Haymaking Machinery.—Haymaking includes the cutting, drying and storage of grasses and leguminous crops. The mower or grass cutter consists of a light two-wheeled frame carrying the cutting mechanism (which is driven by gearing from the wheels), a seat for the driver, and a pole or shafts by which the machine is hauled. Mowers are usually drawn by two horses, though tractors also are employed: small one-horse machines are used in hilly districts and on small holdings. The cutting mechanism consists of the cutter bar (a long flat steel bar to which slotted fingers are bolted), and the knife (a long bar of smaller section than the cutter bar to which triangular steel blades are riveted). The cutter bar is carried on shoes or runners and follows, within limits, the irregularities of the land and can be lifted by the driver to clear obstructions. The grass is cut by the movement of the knife to and fro between the fingers in the cutter bar. The cut grass is left behind on the ground in a continuous "swath": this is pushed on one side by means of a hinged board attached to the end of the cutter bar in order to clear a path for the mower on its next round. The usual width of cut of a mower is 4 ft. 6 in. but both smaller and larger sizes are made. Special cutter bars are also made for attachment to tractors; these have a universal joint for actuating the knife from the engine.

Various machines are available for turning the grass in order to assist natural drying. The hay-turner or tedder which was one of the first machines used for this purpose has a series of tines or teeth attached to a skeleton cylinder fixed on the axle of the machine and driven by gearing from the wheels. A metal shield is placed over the forward and upper part of the cylinder while the back is uncovered. When the tines rotate in a forward direction they pick up the grass and carry it round in the machine and throw it out backwards, spreading it evenly over the ground. When the tines rotate in the reverse direction the grass is merely knocked out backwards and stands exposed to the air. Modern practice favours the use of combined swath-turners, side-delivery-rakes and tedders which may be quickly adapted for each operation. Swath-turners are used for turning over the swaths without dispersing the grass. This operation is performed by means of spring tines which revolve across the swath as the machine proceeds. When the machine is used as a tedder, the tines revolve at double the speed in the reverse direction. It should be noted that swath-turners must follow in the track of the mower, while the hay-turner can be used across the field. Side-delivery-rakes are employed for raking the partially made hay into windrows. The machine is carried on two main wheels and a small trailing wheel. The commonest type has four horizontal rake bars fitted with spring-mounted, vertical steel tines. These bars are mounted at each end on revolving disks set at an angle to the frame behind the driver's seat, and are driven by gearing from the main shaft. The tines are mounted on each rake bar in three sections, the middle one of which is readily detachable. If the middle section is removed the swaths are merely turned over. If all three sections are used the hay is swept to one side and left in a windrow. The horse rake is being displaced by the side-delivery-rake for gathering purposes

but is still used for cleaning fields afterwards. It consists of a number of curved steel tines, extending the whole width of the machine, carried on a light frame with two wheels. The teeth are often adjustable, both for pressure and pitch, so that the ground may be either closely or lightly raked. A ratchet-gear fitted to the wheels provides the means for depositing the load which the rake has collected. The use of hay sweeps or hay loaders is steadily displacing hand forking. Which method is adopted depends largely on the farm and the prevailing weather. In large fields and where the ricks are built in the fields, hay sweeps are usually employed. In smaller fields and where it is necessary to cart the hay some distance to the homestead, loaders are more useful. The hay sweep consists of a frame carried on two widely-spaced travelling wheels, and a large number of long wooden teeth or a wooden platform projecting forward from the frame. The hay is swept up as the implement moves forward, drawn, as a rule, by two horses hitched to each side of the sweep. When the sweep is full the teeth or platform is raised slightly from the ground and the machine is driven to the rick and unloaded. Hay loaders are of two distinct types: the apron and the reciprocating fork. The former consists of a gathering drum fitted with spring teeth mounted on a main axle and an endless apron or web. The hay is picked up by the gathering drum and delivered to the travelling web, which elevates it to the waggon or cart. In the reciprocating-fork machine, hay is worked up the loader by means of shaker rods and tines operated by crank shafts, driven by chains from the travelling wheels. Loaders usually pick up hay from the windrows. The loader is mounted on a frame carried on four travelling wheels, and is drawn behind a waggon or lorry. Where the land is laid in ridge and furrow hay-loaders are at a disadvantage.

Silage Cutters and Blowers.—Silage or ensilage is herbage stored in a green moist state. Silage possesses certain advantages as a feeding stuff, and the practice of growing succulent fodder crops for making it, particularly in wet districts, is now a common one. Certain crops which are unsuitable for making hay can be turned into silage. Silage may be stored in pits, stacks or in specially constructed tower silos. For making silage the crop is mown green and cut up into short lengths. Portable combined silage cutters and blowers are employed to reduce the mown crop to the required fineness and to convey it into the silo. A belt conveyer carries the fodder along the feed trough where it is gripped by a pair of rollers, the upper one of which is floating. From these rollers it passes to the knives, which are readily adjustable without altering their set, and are mounted on a fly-wheel together with the fan blades. The whole is enclosed in a casing to which is connected a metal duct running up into the silo and as the chopped fodder leaves the knives it is blown into the silo. Another type of silage cutter is fitted with spiral knives of the lawn-mower type—the fan being situated at the side of the machine and the fodder conveyed to it by worm or other feeding device.

Grain Harvesting and Threshing Machinery.—Although in certain parts of the world cereal crops are harvested only for their grain, both in intensively farmed countries and in primitive countries great importance is attached to the straw. In intensively farmed countries straw is used for food and litter for the cattle and is converted into manure: in primitive countries where fodder is scarce the straw is bruised and fed to the farm animals. These several conditions mainly determine the type of machinery required: other factors are land tenure—since a small-holder does not as a rule use an expensive or complicated machine—and climate. Reapers are the simplest machines used for harvesting grain crops. There are two types of reapers, namely, the manual delivery and the self-delivery or sail-reaper. The former type is very similar to the mower (see above) but has a light wooden frame-work attached to the cutter bar for collecting the cut corn which is raked off by hand and dropped in heaps for making sheaves. These heaps must be cleared away before the machine can cut another strip and it is usual to cut the crop across the field, the reaper running idle on the return journey. Often combined mowers and reapers are used. The self-delivery or sail-reaper is mounted on one main driving wheel having a fixed cutter-bar carried on travelling wheels at either end which may be adjusted for height of cut.

Behind the cutter-bar is a platform on to which the corn falls and from which it is swept to one side by four rakes working on arms attached to a capstan on the main frame and driven from the land-wheel. This machine leaves a clear path for cutting the next strip and the machine is able to travel round and round the field.

Self-binders, which deliver the corn bound in sheaves, often known simply as binders, are really modifications of sail-reapers with the addition of elevating and tying mechanism. Binders are usually hauled by three horses or by tractors. Certain modifications have been introduced to enable higher travelling and cutting speeds to be used when the binders are drawn by tractors, and in some machines the cutting and binding mechanism is driven from the engine of the tractor. The sheaves are either thrown to the ground at the side of the machine or collected by a sheaf carrier and dropped in heaps to facilitate stooking or shocking. Combined harvester-threshers were devised for harvesting in the dry climates of North and South America, Australia and South Africa.

Threshing machines are sometimes fitted with mechanical or self-feeders and conveyers are used for carrying the sheaves from the rick to the thresher. In America the thresher is usually of larger capacity than the English machine. The straw cavings and chaff are all blown through piping to a distance and deposited in heaps. In this way the straw is much broken, contrary to English practice, where straw is expected to be delivered in an unbroken condition.

Corn [Maize] Harvesting and Threshing Machinery.—The extensive cultivation of maize in America and elsewhere has led to the development of special machines for harvesting and threshing this crop, which may be cut and bound into sheaves or merely headed. The corn binder like the grain binder has cutting, elevating and tying devices and is carried on a framework with one large wheel (which drives the mechanism) and two or three smaller wheels. The stalks are cut between a fixed knife and movable knives attached to two endless chains which rotate as the machine traverses the row. There is also a device to grip the stalks and to convey them to the binding platform from which they are either dropped on the ground for shocking or elevated to a waggon drawn alongside the binder. The corn header or picker takes the ears or cobs from the standing stalks, removes the husks and then elevates the cleaned ears into a waggon drawn alongside the machine. The stalks are left standing and the husks are dropped on the ground. The corn sheller removes the kernels from the ears, cleans the shelled corn and separates it from the cobs and other foreign matter. There is also a device to separate any loose kernels from the shredded material. The ears are afterwards put through a sheller for extracting the kernels.

Elevators.—Where large quantities of hay and corn require to be stacked, a great saving in manual labour is effected by the use of elevators. The principal type of elevator consists of a hopper, a long trough and an endless web fitted with forks. The whole is mounted on a frame carried by four wheels and for convenience in transport the machine is made in sections so that it can be folded. The material is fed into the hopper, from which it is picked by the forks and conveyed up the trough to the top of the stack. Elevators may be driven by horse gear, internal combustion engine, or, when used for stacking straw, direct from the threshing machine.

Root Harvesting Machinery.—The increased cost of labour and the extension of root crops grown for the market (e.g., sugar-beet) as distinct from those consumed on the farm, have led to the development of mechanical devices for lifting the roots and performing all subsequent operations necessary to produce a marketable product. The difficulties are very much greater than in the case of standing crops, and since apart from other factors the soil, in all conditions from clay to sand, requires to be separated from the roots, machines have yet to be designed which will perform efficiently under a wide range of conditions all the requisite operations. Only certain machines of particular importance can be described here. The simplest mechanical device for lifting potatoes is the potato plough which has a series of prongs for raising the tubers as the implement is drawn through the ground. More elaborate machines, designed both to raise and

separate the tubers from the soil, are of two distinct types—the spinner and the elevator. Spinners are carried on two land wheels and have a broad scoop share which runs under the ridge and loosens the earth around the tubers. Immediately behind the share is the spinner, consisting of a series of forks rotating at right angles to the track of the machine. The forks are set to work at about the same depth as the share and, as they turn, throw out the potatoes to one side, leaving them in more or less compact rows. Elevators comprise a share and an elevating device actuated by gearing from the two travelling wheels. The machine has a main and a fore carriage, the latter being carried on two small wheels. As it moves forward, the potatoes and a certain amount of earth are raised by the share and carried up by a travelling web, which allows most of the earth to fall through before the potatoes reach the top; the potatoes then either fall to the ground or are delivered to a further cleaning and separating device—usually composed of oscillating forks. The depth of working can be regulated. Both types of machine leave the potatoes on the surface to be picked up and bagged by hand: no satisfactory machine to lift and bag potatoes at one operation has yet been evolved. Potato sorting and grading is effected by a separate machine, consisting of a series of riddles.

The simplest form of beet-lifter consists of a special share attached to an ordinary plough beam. There are many different kinds of digging shares, but only two main types, those which exert a pressure on both sides of the beet, leaving it loose but still standing upright in the ground, and those which exert pressure on one side only and tend to push the beet to one side. With all these machines the beet is afterwards pulled by hand and the tops cut off with a knife, the beet being subsequently loaded by hand into carts. Many machines have been invented for topping beet mechanically, either before or after the roots are lifted. The cutting implement is usually either a revolving disc or a hoe blade generally fixed diagonally across the row. These machines are built either simply as toppers, or in combination with lifters. It cannot, however, be said that an entirely satisfactory topping and lifting machine has yet been produced, though some will do useful work under favourable conditions. See also AGRICULTURAL MACHINERY. See F. N. G. Kranich, *Farm Equipment for Mechanical Power*. (B. J. O.; H. G. R.)

THE UNITED STATES

Among the many devices invented for large-scale farming in the United States a few are of sufficient importance to call for full description here.

The Harvester-thresher or Combine was originally developed for harvesting the small grains in the semi-arid regions of the western United States; it is, however, no longer limited to this area nor merely to the harvesting of small grain. It is now being employed in increasing numbers in the Central States, the East and in the South. Its introduction into these regions of small farms and varying climatic conditions is the result of several innovations, chief among which are the development of a small-type machine that can be operated by one man if necessary. Not only is the smaller machine more suitable to the small acreages in these regions, it is less costly and requires a much smaller investment than the larger machines used in the West. Certain other improvements in the combine have also been influential in extending its use, particularly those making it adapted for harvesting such crops as soy beans, cowpeas, grain sorghums, flax, buckwheat, rice, and clover, alfalfa and timothy seed.

Previously the combine could be used successfully only where the grain ripened evenly and was free from weeds and other green material. Now with the development of a new machine, the windrow harvester, the farmer can begin cutting his grain at the same time he would go into his field with an ordinary binder, which is usually a week to ten days earlier than the combine can be started. The windrow machine, or windrow-harvester, as it is called, is virtually a right-hand header with facilities for delivering the cut grain in a windrow on the stubble. It is important that the stubble be cut high enough so that it will hold the cut grain and allow air to circulate underneath and cure it quickly. The grain is

laid in the windrow with the heads overlapping the butts similar to that in which shingles are laid on a roof. After two or three days of good drying weather, a harvester-thresher equipped with a pick-up device is brought into the field and run in the same direction as the windrow harvester; the grain is picked up just as a man would raise shingles from a roof and goes into the combine to be threshed and handled from there on just as if it were being cut from the stubble in the usual manner. The windrow method has been developed to supplement the combine method of harvesting; its use is especially advantageous where grain is weedy or ripens unevenly or weather hazards are prevalent at the time of harvesting. Frequently a farmer begins his harvest by windrowing his grain and later when conditions are right he removes the pick-up device from the harvester-thresher and finishes the harvest by the straight combine method.

There are several types of combines now in use. The large machine developed for use in the Great Plains is now equipped with an auxiliary engine and may be pulled by horses or tractor. It is made in sizes that cut from 9 to 24 ft. swaths. Machines of this type cutting from 9 to 12 ft. swaths are used somewhat in the Corn Belt and require from 6 to 8 horses, or tractors of 12 to 15 drawbar horse-power. On the hilly farms in the Pacific North-west as many as 30 horses are sometimes used.

Another type of combine introduced in 1926 cuts a 9 or 10 ft. swath and is drawn by a tractor with a direct power drive from the tractor to operate the cutting and threshing machinery. This type can be operated by one man and has the further advantage of being less expensive than the large combines with auxiliary motors.

The smallest type of combine now on the market, also introduced in 1926, is one mounted on the tractor from which it obtains its power. It cuts an 8-ft. swath, the cutter bar being directly in front of the tractor. It also differs radically from all others in that an auger is used instead of canvases on the cutting platform. This small power machine is used mostly on farms which have small acreages of grain.

Combines can be equipped with grain tanks to store the grain until it can be run into a motor truck for hauling to the farm or market. Where wagons are used for hauling the grain away from the combine the grain is usually run directly into a trailing wagon. When one wagon is full, another is substituted to catch the grain while the loaded one is hauled away. The straw is spread behind the machine uniformly over the land by means of special equipment for the purpose. It can then be plowed under without difficulty. Without the straw-spreader equipment the straw is left in a narrow strip and must be raked into piles for burning or hauling.

Mechanical Cotton-harvesters.—Until recent years the world's cotton crop was harvested entirely by hand. The first application of mechanical principles in harvesting the crop in the United States was in connection with the sled or stripper devised for pulling or snapping cotton. This rather primitive, or home-made, affair was an outgrowth of the practice of farmers in certain parts of Texas and Oklahoma who began along about 1900 to pull or snap their cotton by hand. In those regions early frosts made it difficult to pick the cotton in the usual manner as the plants become too brittle for picking the bolls without pulling the entire burr. Adverse weather conditions at cotton picking time, low prices for cotton, and scarcity of labour also were factors making it necessary to adopt rapid and more economical methods of harvesting. The sled method based on the hand method of pulling or snapping was developed under these conditions along about 1918 and used successfully for several seasons but did not come into prominence until the fall of 1926 when Western farmers again suffered from adverse economic conditions.

Two main types of sleds, the finger type and the slot type, are now in general use. The sleds are commonly drawn by two horses and operated by one or two men. The finger type is adapted to small cotton of the kind grown in the Staked Plains area, and the slot type for use in the bottom lands of the plains area where cotton grows more vigorously and taller. The finger type is characterized by toothed arrangements, not unlike mower guards,

attached to the front of the sled where they strip all bolls from the stalks as one strips leaves from a tree branch by drawing it through the fingers of the hand. The harvested cotton falls or is raked back into a box for holding until the end of the row is reached.

The slot type differs from the finger type in that the stripping action is done by narrow slots running through the centre of the sled from front to rear. The slots become narrow and slope upward toward the rear of the sled so that the cotton is stripped from the stalks as they pass into the slots. Well-constructed sleds often gather as much as 95% of the cotton from the plants.

Recently manufacturers of farm machinery have made marked progress in developing an improved harvester of the sled type. The slot idea is retained but the cotton is stripped from the plants by revolving rollers, or by lugs attached to endless chains. The snapping rolls are either twisted, perforated, or spiked to provide a rough surface for removing the cotton from the plants. The stripped cotton is either raked or conveyed from beneath the snapping rolls to a box in the rear, provision being made in some cases to screen out some of the dirt and trash. The endless chain type, however, has no separate conveyor as the stripper fingers convey the cotton to the box.

The newest mechanical cotton pickers are known as the spindle type and have been built to operate with horses or tractor. While these machines are still regarded as in the experimental stage, they have made satisfactory field tests during the past season. The cotton row passes between two revolving cylinders set upright. The cylinders are filled with numerous spindles covered with barbs that catch the cotton and wind it around the spindles. A sleeve arrangement over each spindle automatically slips the cotton off and it is blown into sacks at the rear of the machine. With the development of these machines, as well as improved sled harvesters, a good start has been made toward placing the harvesting of the cotton crop on a mechanical basis.

Hay Stacking Machinery.—In western United States where hay is largely stacked in the field instead of being stored in the barn, stacking machinery is used to eliminate much of the hand labour. Stackers can be used to advantage on many farms in other parts of the country as well as in the West, especially when farm labour is scarce. They enable the farmer to handle hay more rapidly than by other methods and usually a smaller number of men will be required. Boys often replace men in some operations when stackers are employed. Loading the hay on wagons by hand and unloading it with a stacker eliminates half of the hand labour. If push rakes or hay loaders are used to move the hay to the stack, pitching by hand is avoided entirely.

There are two principal types of stackers in common use. One type handles the hay by means of the single or double harpoon fork, grapple fork, or sling, and the other type has long wooden teeth similar to those of the push rake on which the hay is placed for elevating to the top of the stack.

Stackers of the first type are usually home-made affairs and are represented by the cable stacker, the pole or derrick stacker, and the tripod stacker. With the cable stacker hay is brought to the stack on wagons or by push rakes. The load is elevated by forks or slings to a carrier which runs on the cable and deposits the load at any desired point on the top of the stack between the poles. The height and length of the stack is limited only by the height of the poles and the length of the cable used. The pole or derrick stacker consists of a single pole set upright and of sufficient length to make a stack of the desired height. A shorter pole (or boom) is fastened at right angles near the top of the upright pole. By means of ropes and pulleys one or two horses elevate the fork or sling load of hay to the outer end of the boom pole which is then swung over the stack where the load is dropped. The upright pole is anchored by means of guy wires. The tripod stacker has 3 poles about 30 ft. long, bolted together at the top and spread out at the bottom far enough to permit a stack to be built under the tripod. The equipment for this outfit consists of three pulleys, a hay rope, a trip rope, and a horse fork.

The second type of stacker is represented by the "overshot,"

the "swing around," and the "combination." Each of these has long wooden teeth, like those of the push rake, on which hay brought from the windrow by push rakes is deposited for elevation to the top of the stack. The overshot stacker is so called because the hay is carried up and over the stacker frame and dropped on the stack. On some forms the stacker head merely slides up an inclined plane and dumps its load on the stack, while on others the stacker head is attached to a frame-work which vaults it up and over. These stackers are mounted on wheels or sled-like frames to facilitate their movement from place to place in the field. The swing around stacker is similar to the overshot except that the stacker head is attached to an arm balanced like an old-fashioned well sweep over the top of a high upright pole. A weight at the far end of the arm counterbalances the load of hay and helps to lift it. This stacker has the advantage of being able to deliver the hay at any desired point on the top of the stack. The combination stacker does the work of both the stacker and the push rake. Stacks a little more than 20 ft. high can be made with the combination stacker. It is most commonly used around the stack to pick up the loads brought in by push rakes, depositing them on the stack from either side or end. In all types of stackers one or two horses furnish the power to elevate the loads of hay to the top of the stack. (L. S. R.)

HARVEY, FREDERICK WILLIAM (1888—), English poet, was born in Gloucestershire. He was educated at Rossall, and studied law, setting up in practice as a solicitor in 1912. He enlisted at the outbreak of the World War, obtaining a commission in 1915, and was captured in 1916. After the war he returned to his solicitor's practice. In addition to four volumes of poetry, he published his experiences as a prisoner in Germany in *Comrades in Captivity* (1920).

His poetry includes: *A Gloucester Lad at Home and Abroad* (1916); *Gloucestershire Friends* (1917); *Ducks* (1919), and *Farewell* (1921).

HARVEY, GABRIEL (c. 1545–1630), English writer, eldest son of a ropemaker of Saffron-Walden, Essex, was born about 1545. He matriculated at Christ's college, Cambridge, in 1566, and in 1570 was elected fellow of Pembroke Hall. Here he formed a lasting friendship with Edmund Spenser, and it has been suggested (*Athen. Cantab.* ii. 258) that he may have been the poet's tutor. Harvey was a good scholar, who has perhaps been judged too exclusively from the brilliant invectives directed against him by Thomas Nashe (*q.v.*). Harvey desired to be "epitaphed as the Inventour of the English Hexameter," and was the prime mover in the literary clique that desired to impose on English verse the Latin rules of quantity. In a "gallant, familiar letter" to M. Immerito (Edmund Spenser) he says that Sir Edward Dyer and Sir Philip Sidney were helping forward "our new famous enterprise for the exchanging of Barbarous and Balductum Rymes with Artificial Verses." The document includes a tepid appreciation of the *Faerie Queene* which had been sent to him for his opinion, and he gives examples of English hexameters illustrative of the principles enunciated in the correspondence. The opening lines—

"What might I call this Tree? A Laurell? O bonny Laurell

Needs to thy bowes will I bow this knee, and vayne my bonetto"—are sufficient to show that Harvey's metrical experiments presented a fair mark for Nashe's wit. "He (Harvey) goes twitching and hopping in our language like a man running upon quagmires, up the hill in one syllable, and down the dale in another," says Nashe in *Strange Newes*, and he mimics him in the mocking couplet:

"But eh! what news do you hear of that good Gabriel Huffe-Snuffe,
Known to the world for a foole, and clapt in the Fleete for a
Runner?"

Harvey exercised great influence over Spenser for a short time, and the friendship lasted even though Spenser's genius refused to be bound by the laws of the new prosody. Harvey is the Hobnoll of his friend's *Shepheards Calender*, and into his mouth is put the beautiful song in the fourth eclogue in praise of Eliza. If he was really the author of the verses "To the Learned Shepheard" signed "Hobynoll" and prefixed to the *Faerie Queene*, he was a good poet spoiled. But Harvey's genuine friendship for Spenser shows the best side of a disposition uncompromising and quarrel-

some towards the world in general. In 1573 ill-will against him in his college was so strong that there was a delay of three months before the fellows would agree to grant him the necessary grace for his M.A. degree. He became reader in rhetoric about 1576, and in 1578 disputed publicly before Queen Elizabeth on her visit to Sir Thomas Smith at Audley End. In 1585 he was elected master of Trinity Hall, of which he had been a fellow from 1578, but the appointment appears to have been quashed at court. Gabriel's brother, Richard, had taken part in the Marprelate controversy, and had given offence to Robert Greene (*q.v.*) by contemptuous references to him and his fellow wits. Greene retorted in his *Quip for an Upstart Courtier* with some scathing remarks on the Harveys, the worst of which were expunged in later editions, drawing attention among other things to Harvey's modest parentage. After Greene's death Harvey published *Four Letters and certaine Sonnets* (1592), in which in a spirit of righteous superiority he laid bare with spiteful fulness the miserable details of Greene's later years. For the controversy with Nashe which followed see NASHE, THOMAS. In 1599 Archbishop Whitgift made a raid on contemporary satire in general, and among other books the tracts of Harvey and Nashe were destroyed, and it was forbidden to reprint them. Harvey spent the last years of his life in retirement at his native place, dying in 1630.

The Letter-Book of Gabriel Harvey, A.D. 1573-80 (1884, ed. E. J. L. Scott, Camden Society), contains rough drafts of the correspondence between Spenser and Harvey, letters relative to the disputes at Pembroke Hall, and an extraordinary correspondence dealing with the pursuit of his sister Mercy by a young nobleman.

Harvey's complete works were edited by Dr. A. B. Grosart with a "Memorial Introduction" for the *Huth Library* (1884-85). G. C. Stone-Smith edited other fragments as *Marginalia* (Stratford-on-Avon, 1913). See also Isaac Disraeli, on "Literary Ridicule," in *Calamities of Authors* (ed., 1840); T. Warton, *History of English Poetry* (ed. W. C. Hazlitt, 1871); J. P. Collier, *Bibliographical and Critical Account of the Rarest Books in the English Language* (1865), and the *Works of Thomas Nashe*.

HARVEY, SIR GEORGE (1806-1876), Scottish painter, son of a watchmaker, was born at St. Ninians, near Stirling, and died at Edinburgh on Jan. 22, 1876. He became a fellow of the Royal Scottish academy in 1829, and its president in 1864. Harvey painted some pictures on subjects drawn from religious and Scottish history, but his best work is in *genre* pictures of Scottish life.

HARVEY, GEORGE BRINTON McCLELLAN (1864-1928), American editor and diplomat, was born in Peacham (Vt.), Feb. 16, 1864. At eighteen he became a reporter on the *Springfield* (Mass.) *Republican*, and later on the *Chicago News* and the *New York World*. He was insurance commissioner of New Jersey in 1890-91 and managing editor of the *New York World*, 1891-93. Then for several years he was engaged in the construction and administration of electric railways, and in 1898 organized a syndicate which secured possession of the lines in Havana, Cuba. The following year he purchased the *North American Review*, which he thereafter edited. During 1900-15 he was president of the publishing house of Harper & Bros., and during 1902-13 was editor of *Harper's Weekly*. In 1903 he purchased the *Metropolitan Magazine*.

Harvey was said to have been the first to suggest (in 1906) Woodrow Wilson, then president of Princeton, as a presidential possibility. In the campaign of 1912 he gave Wilson strong support, but after the latter's nomination an estrangement developed. In 1916 Harvey urged the election of Charles E. Hughes, the Republican candidate for president. He was strongly opposed to the League of Nations on the ground that it involved the yielding of national sovereignty. In 1918 he established the *North American Review's War Weekly*, later called *Harvey's Weekly*, which bitterly denounced the Wilson administration. In 1921 he was appointed ambassador to England by President Harding, a position which he held till Dec. 1923. He was editorial director of the *Washington Post* in 1924-25. He died at Dublin, N.H., Aug. 20, 1928.

Harvey's books include *Women* (1908), *The Power of Tolerance*,

and *Other Speeches* (1911), and *Henry Clay Frick, the Man* (1928).

See Willis Fletcher Johnson, *George Harvey* (1929).

HARVEY, WILLIAM (1578-1657), English physician, the discoverer of the circulation of the blood, was born at Folkestone on April 1, 1578. He was educated at Caius college, Cambridge, and then proceeded to Padua to study medicine under H. Fabricius and became doctor of medicine in April 1602. Returning to England, he settled in London. He was admitted (June 1607) fellow of the Royal College of Physicians, and in 1609 obtained the reversion of the post of physician to St. Bartholomew's hospital, and in the same year he succeeded to the post.

In 1616 he began a course of lectures at the College of Physicians in which he first brought forward his views upon the movements of the heart and blood. Meantime his practice increased, and he had the lord chancellor, Francis Bacon, and the earl of Arundel among his patients. He was physician extraordinary to James I., and physician in ordinary to Charles I. In 1628 he published the *Exercitatio anatomica de motu cordis et sanguinis*; between 1629 and 1632 he travelled on the Continent, principally in Italy with James Stuart, afterwards duke of Richmond. Four years later he accompanied the earl of Arundel on his embassy to the emperor Ferdinand II. He returned to his practice in London at the close of the year 1636, and accompanied Charles I. in one of his journeys to Scotland (1639 or 1641), and was in attendance on the king at the battle of Edgehill (Oct. 1642), and then followed Charles I. to Oxford.

While with the king at Oxford he was made warden of Merton college, but a year later, in 1646, that city surrendered to Fairfax, and Harvey returned to London. He was now 68 years old, and, having resigned his appointments and relinquished the cares of practice, lived in learned retirement with one or other of his brothers. It was in his brother Daniel's house at Combe that Dr. (afterwards Sir George) Ent, a faithful friend and disciple (1604-89), visited him in 1650. The work on which he had been chiefly engaged at Oxford, and indeed since the publication of his treatise on the circulation in 1628, was an investigation into the subject of generation. Charles I. had put the royal deer parks at Windsor and Hampton Court at his disposal, and had watched his demonstration of the growth of the chick with no less interest than the movements of the living heart. Harvey had collected a large number of observations, and Ent succeeded in obtaining the manuscripts, with authority to print them or not. The result was the publication of the *Exercitationes de generatione* (1651).

This was the last of Harvey's labours. He had now reached his 73rd year. His theory of the circulation was generally accepted by the most eminent anatomists both in his own country and abroad and he was known and honoured throughout Europe. In 1654 he was elected president of the College of Physicians but declined the honour, though he enriched the college with many gifts.

Harvey died on June 3, 1657, and was buried at Hempstead, Essex; in 1883 his remains were placed in the Harvey chapel in the church there.

John Aubrey says: "In person he was not tall, but of the lowest stature; round faced, olivaster complexion, little eyes, round, very black, full of spirits; his hair black as a raven, but quite white 20 years before he died." The best known portrait of him extant is by Cornelius Jansen in the library of the College of Physicians.

Harvey's Work on the Circulation.—In estimating the character and value of the discovery announced in the *Exercitatio de motu cordis et sanguinis*, it is necessary to bear in mind the previous state of knowledge. Aristotle taught that the blood was elaborated from the food in the liver, thence carried to the heart, and sent through the veins over the body. The Alexandrian physicians, Erasistratus and Herophilus, taught that, while the veins carried blood from the heart to the members, the arteries carried a subtle kind of air or spirit. Galen discovered that the arteries were not, as their name implies, mere air-pipes, but that they contained blood as well as vital air or spirit and he believed that the nerves (*νεῦρα*) arose from the brain and conveyed "animal spirits" to the body. The views of Galen remained current till the 16th

century. The physicians of that period had developed certain doctrines concerning the vascular system which we may thus summarize: *First*, the blood is not stagnant, but moves in the body. But no one had a conception of a continuous stream returning to its source (a circulation in the true sense of the word) either in the system or in the lungs. If they used the word *circulatio*, as did Caesalpinus, it was as vaguely as the French policeman cries "Circulez." The movements of the blood were in fact thought to be slow and irregular in direction as well as in speed, like the "circulation" of air in a house, or of a crowd in the streets. *Secondly*, they supposed that one kind of blood flowed from the liver to the right ventricle of the heart, and thence to the lungs and the general system by the veins, and that another flowed from the left ventricle to the general system by the arteries. *Thirdly*, they supposed that the septum of the heart was pervious and allowed blood to pass directly from the right to the left side. *Fourthly*, they had no conception of the functions of the heart as the motor power of the movement of the blood. They doubted whether its substance was muscular; they supposed its pulsation, like that of the arteries, to be due to expansion of the contained spirits.

Of the great anatomists of the 16th century, Vesalius (*De humani corporis fabrica*, 1542) ascertained that the septum between the right and left ventricles is complete, though he could not bring himself to deny the invisible pores which Galen's system demanded. Servetus, in his *Christianismi restitutio* (1553), goes somewhat farther, and, from this anatomical fact and the large size of the pulmonary arteries he concludes that there is a communication in the lungs by which blood passes from the pulmonary artery to the pulmonary vein. It seems doubtful whether even Servetus rightly conceived of the entire mass of the blood passing through the pulmonary artery and the lungs. Indeed, a true conception of the lesser circulation as a transference of the whole blood of the right side to the left was impossible until the corresponding transference in the greater or systematic circulation was discovered. Lastly, the system of valves in the veins had been elaborately set forth and illustrated by Harvey's own teacher Fabricius.

The way then to Harvey's great work had been paved by the discovery of the valves in the veins, and by that of the lesser circulation, but the significance of the valves was unsuspected and the fact of even the pulmonary circulation was not generally admitted.

In his treatise Harvey proves (1) that it is the contraction, not the dilatation, of the heart which coincides with the pulse, and that the ventricles, as true muscular sacs, squeeze the blood which they contain into the aorta and pulmonary artery; (2) that the pulse is produced by the arteries being filled with blood; (3) that there are no pores in the septum of the heart, so that the whole blood in the right ventricle is sent to the lungs and round by the pulmonary veins to the left ventricle, and also that the whole blood in the left ventricle is again sent into the arteries, round by the smaller veins into the venae cavae, and by them to the right ventricle again—thus making a complete "circulation"; (4) that the blood in the arteries and that in the veins is the same blood; (5) that the action of the right and left sides of the heart, auricles, ventricles and valves, is the same, the mechanism in both being for reception and propulsion of liquid and not of air; (6) that the blood propelled through the arteries to the tissues is not all used, but that most of it runs through into the veins; (7) that there is no to-and-fro undulation in the veins, but a constant stream from the distant parts towards the heart; (8) that the dynamical starting-point of the blood is the heart and not the liver.

The method by which Harvey arrived at his solution of the most fundamental and difficult problem in physiology is well worthy of attention. He had not only furnished himself with all the knowledge that books and the instructions of the best anatomists of Italy could give, but, by a long series of dissections, had gained a far more complete knowledge of the comparative anatomy of the heart and vessels than any contemporary. Thus equipped, he tells us that he began his investigations into the

movements of the heart and blood by seeing their action in living animals. He minutely describes what he saw and handled in dogs, pigs, serpents, frogs and fishes, and even in slugs, oysters, lobsters and insects, in the transparent shrimp, and lastly in the chick while still in the shell. He particularly describes his observations and experiments on the ventricles, the auricles, the arteries and the veins. He shows how the arrangement of the vessels in the foetus supports his theory. He adduces facts observed in disease as well as in health to prove the rapidity of the circulation. He explains how the mechanism of the valves in the veins is adapted to favour the flow of the blood to the heart. He estimates the capacity of each ventricle, and reckons the rate at which the whole mass of blood passes through it. He elaborately and clearly demonstrates the effect of obstruction of the blood-stream in arteries or in veins, by the forceps in the case of a snake, by a ligature on the arm of a man, and illustrates his argument by figures. These results can only be explained by the constant circulation of the same blood. Lastly, in the 15th, 16th and 17th chapters, he adds certain confirmatory evidence, as to the effect of position on the circulation, the absorption of animal poisons and of medicines applied externally, the muscular structure of the heart and the necessary working of its valves. The whole treatise, which occupies only 52 pages of print, is a model of accurate observation, patient accumulation of facts, ingenious experimentation, cautious hypothesis and logical deduction.

In one point only was the demonstration of the circulation incomplete. Harvey did not see the capillary channels by which the blood passes from the arteries to the veins. This gap in the circulation was supplied thirty years later by the great anatomist Marcello Malpighi, who described the capillary circulation four years after Harvey's death. But the existence of the channels first seen by Malpighi was already clearly pointed to by Harvey's reasoning.

Harvey's Work on Generation.—The *Exercitationes de generatione* is between five and six times as long as the *Exerc. de motu cord. et sang.*, and is followed by excursus *De partu*, *De uteri membranis*, *De conceptione*; but, though the fruit of as patient and extensive observations, its value is far inferior. The subject was more abstruse, and inaccessible to proper investigation without the aid of the microscope. Fabricius, Harvey's master, in his work *De formatione ovi et pulli* (1621) and another pupil of Fabricius, Volcher Coiter (1534-?) of Nuremberg, were among the few who had preceded Harvey in modern times. The 72 chapters which form the book lack the co-ordination so conspicuous in the earlier treatise, and some of them seem almost like detached chapters of a system which was never completed or finally revised.

Aristotle had believed that the male parent determined the form of the future embryo, while the female only nourished and nursed the seed. Galen taught that each parent contributes seeds, the union of which produced the young animal. Harvey, after speaking with due honour of Aristotle and Fabricius, begins "ab ovo," for he says, "almost all animals, even those which bring forth their young alive, and man himself, are produced from eggs." This dictum, usually quoted as *omne vivum ex ovo*, was a prevision of genius, and was not proved until K. E. von Baer discovered the mammalian ovum in 1827. Harvey proceeds with a careful anatomical description of the ovary and oviduct of the hen, describes the new-laid egg, and then gives an account of the appearance seen on the successive days of incubation. Commenting on Aristotle and Fabricius, he declares against spontaneous generation, proves that there is no *semen foemineum*, that the chalazae of the hen's eggs are not the *semen galli*, and that both parents contribute to the formation of the egg. He describes accurately the first appearance of the ovarian ova as mere specks, their assumption of yolk and afterwards of albumen. He describes two methods of production of the embryo from the ovum: one is *metamorphosis*, or the direct transformation of pre-existing material, as a worm from an egg, or a butterfly from an *aurelia* (chrysalis); the other is *epigenesis*, or development with addition of parts, the true generation observed in all higher animals. Chapters xlvii.-l. are devoted to the abstruse question of the

efficient cause of generation, which, after much discussion of the opinions of Aristotle and of Sennertus, Harvey refers to the action of both parents as the efficient instruments of the first great cause. He then goes on to describe the order in which the several parts appear in the chick. He states that the *punctum saliens* or foetal heart is the first organ to be seen, and explains that the nutrition of the chick is not only effected by yolk conveyed directly into the midgut, as Aristotle taught, but also by absorption from yolk and white by the umbilical (omphalomeseraic) veins; on the fourth day of incubation appear two masses (which he oddly names *vermiculus*), one of which develops into three vesicles, to form the cerebrum, cerebellum and eyes, the other into the breast-bone and thorax; on the sixth or seventh day come the viscera, and lastly, the feathers and other external parts. Harvey points out how nearly this order of development in the chick agrees with what he had observed in mammalian and particularly in human embryos. He notes the bifid apex of the foetal heart in man and the equal thickness of the ventricles, the soft cartilages which represent the future bones, the large amount of liquor amnii and absence of placenta which characterize the foetus in the third month; in the fourth the position of the testes in the abdomen, and the uterus with its Fallopian tubes resembling the uterus bicornis of the sheep; the large thymus; the caecum, small as in the adult, not forming a second stomach as in the pig, the horse and the hare; the lobulated kidneys, like those of the seal ("*vitulo*," sc. *marino*) and porpoise, and the large suprarenal veins, not much smaller than those of the kidneys (li.-lvi.). He failed, however, to trace the connection of the urachus with the bladder. In the following chapters (lxiii.-lxxii.) he describes the process of generation in the fallow deer or the roe. Much of Harvey's work on generation was superseded during the next 25 years by that of Malpighi. The remaining writings of Harvey are unimportant.

Of Harvey as a practising physician we know very little. Aubrey tells us that "he paid his visits on horseback with a foot-cloth, his man following on foot, as the fashion then was." He adds—"Though all of his profession would allow him to be an excellent anatomist, I never heard any that admired his therapeutic way. I knew several practitioners that would not have given threepence for one of his bills" (the apothecaries used to collect physicians' prescriptions and sell or publish them to their own profit), "and that a man could hardly tell by his bill what he did aim at." However this may have been, and rational therapeutics was impossible when the foundation stone of physiology had only just been laid, we know that Harvey was an active practitioner, performing such important surgical operations as the removal of a breast, and he turned his obstetric experience to account in his book on generation. Some good practical precepts as to the conduct of labour are quoted by Percivall Willughby (1596-1685). He also took notes of the anatomy of disease; these unfortunately perished with his other manuscripts. We may regard him as a forerunner of Morgagni, for Harvey saw that pathology is but a branch of physiology, and like it must depend on accurate anatomy. He speaks to this purpose in his first epistle to Riolan. The only specimen we have of his observations in morbid anatomy is his account of the post-mortem examination made by order of the king on the body of the famous Thomas Parr, who died in 1635, at the reputed age of 152. Harvey insists on the value of physiological truths for their own sake, independently of their immediate utility; but he himself gives us an interesting example of the practical application of his theory of the circulation, in the cure of a large tumour by tying the arteries which supplied it with blood (*De generat. Exerc.*, xix.).

BIBLIOGRAPHY.—The following is believed to be a complete list of all the known writings of Harvey, published and unpublished:—*Exercitatio anatomica de motu cordis et sanguinis*, (Frankfort-on-Main, 1628); *Exercitationes duae anatomicae de circulatione sanguinis, ad Johannem Riolanum, filium, Parisiensem* (Cambridge, 1649); *Exercitationes de generatione animalium, quibus accedunt quaedam de partu, de membranis ac humoribus uteri, et de conceptione* (1651); *Anatomia Thomae Parr*, first published in the treatise of Dr. John Betts, *De ortu et natura sanguinis* (1669). Letters: To Caspar Hoffmann of Nuremberg, May 1636; to Schlegel of Hamburg, April 1651; three to Giovanni Nardi of Florence, July 1651, Dec. 1653, and Nov. 1655; two to Dr. Morison of Paris, May 1652; two to Dr. Horst of

Darmstadt, Feb. 1654-55 and July 1655; to Dr. Vlackveld of Haarlem, May 1657. His letters to Hoffman and Schlegel are on the circulation; those to Morison, Horst and Vlackveld refer to the discovery of the lacteals; the two to Nardi are short letters of friendship. All these letters were published by Sir George Ent in his collected works (Leyden, 1687). Of two ms. letters, one, on official business to the secretary, Dorchester, was printed by Dr. Aveling, with a facsimile of the crabbéd handwriting (*Memorials of Harvey*, 1875), and the other, about a patient, appears in Dr. Robert Willis's *Life of Harvey* (1878). *Praelectiones anatomicae universalis per me Gul. Harveium medicum Londinensem, anat. et chir. professorem, an. dom.* (1616), aetat. 37,—ms. notes of his Lumeian lectures in Latin—are in the British Museum library; an autotype reproduction was issued by the College of Physicians in 1886. An account of a second ms. in the British Museum, entitled *Gulielmus Harveius de musculis, motu locali*, etc., was published by Sir G. E. Paget (*Notice of an unpublished ms. of Harvey*, 1850). The following treatises, or notes towards them, were lost either in the pillaging of Harvey's house, or perhaps in the Fire of London, which destroyed the old College of Physicians: *A Treatise on Respiration*, promised and probably at least in part completed (pp. 82, 550, ed. 1766); *Observationes de usu Lienis*; *Observationes de motu locali*, perhaps identical with the above-mentioned manuscript; *Tractatum physiologicum*; *Anatomia medicalis* (apparently notes of morbid anatomy); *De generatione insectorum*. The fine edition of Harvey's *Works*, published by the Royal College of Physicians in 1766, was superintended by Dr. Mark Akenside; it contains the two treatises, the account of the post-mortem examination of old Parr, and the six letters enumerated above. A translation of this volume by Dr. Willis, with Harvey's will, was published by the Sydenham Society (1847).

A copy of the *De generatione* with numerous notes in Harvey's own hand, referring chiefly to his reading of Aristotelian works, is in private possession.

There is a convenient photographic facsimile of the work on the circulation issued by C. Moreton (1894). The standard translation of his collected works is still that of Thomas Willis (1847). A convenient reprint of the translation by Willis of the work on the circulation is available (1906).

The literature that has arisen on Harvey and his great discovery would fill a library. A bibliography by Geoffrey Keynes has been published (1928), and a further account of the works of Harvey on the occasion of the celebration of the tercentenary of the publication of the work on the circulation by the Royal College of Physicians, London (1928). Of recent writings on Harvey mention may be made of the life by D'Arcy Power (1897); the facsimile of Harvey's Paduan diploma issued by the Royal College of Physicians, with pamphlet by J. F. Payne (1908); the volume of *Portraits of Harvey* published by the Historical Section of the Royal Society of Medicine (1913). The Harveian oration at the Royal College of Physicians is devoted to an annual exposition of some part of his work. Among the recent orations are those by W. Osler, *The Growth of Truth* (1906); H. R. Spencer, *William Harvey, Obstetric Physician and Gynaecologist* (1921); A. Chaplin, *Medicine in the Century before Harvey* (1922); C. Singer, *Discovery of the Circulation of the Blood* (1922) gives an exposition of the history of this event.

(P. H. P. S.; C. Sr.)

HARVEY, WILLIAM HENRY (1811-1866), Irish botanist, was born on Feb. 5, 1811, at Summerville, near Limerick, and was educated at Kildare. He became an authority on algae and Cape flora, on which he published extensive works. He died at Torquay on May 15, 1866.

HARVEY, a city of Cook county, Ill., U.S.A., 20m. S. of the Chicago "Loop." It is served by the Baltimore and Ohio Chicago Terminal, the Illinois Central, and the Grand Trunk railways and is near the Calumet river. The population was 9,216 in 1920 (22% foreign-born white), and was estimated locally at over 20,000 in 1928. It is a residential suburb, and also has important manufactures, including mine, oil-well, road and ditching machinery, railway cars, foundry equipment, cement, gas stoves, automobiles, electric travellers and aluminium-ware. Harvey was named for a Chicago capitalist. It was founded in 1890, chartered as a city in 1895, and in 1921 adopted a commission form of government.

HARVEY STEEL PROCESS. Named after the inventor, H. A. Harvey, an American metallurgist, this is a process of hardening the surface of steel, used in the production of armour plate. The essence of the process is that the plate is face-hardened by cementation of its surface. The plate is exposed in a furnace to great heat for a considerable period, about a fortnight, and covered with finely pulverized carbon. The surface of the steel is thus penetrated and carburized to a considerable depth, the front of the plate becoming of a different composition from that of the back. After thus being exposed to cementation, the plate

is withdrawn and cooled slowly to a dull red, when it is suddenly chilled by a water spray. (See IRON AND STEEL; ARMOUR PLATE; METALLURGY.)

HARWICH, municipal borough and seaport, Harwich parliamentary division, Essex, England, on the extremity of a small peninsula projecting into the estuary of the Stour and Orwell, 70 m. N.E. by E. of London by the L.N.E. railway. Pop. (1921) 13,046, including Halstead, added to the borough in 1917. Harwich (Herewica, Herewyck) formed part of the manor of Dovercourt. It became a borough in 1319 by a charter of Edward II., which was confirmed in 1342 and 1378, and by each of the Lancastrian kings. Harwich received charters in 1547, 1553 and 1560. In 1604 James I. gave it a charter which provided a new constitution, and from this date begins the regular parliamentary representation. Two burgesses had attended parliament in 1343. Until 1867 Harwich returned two members; it then lost one, and in 1885 its representation was merged. In 1252 Henry III. granted to Roger Bigod a market here every Tuesday, and a fair on Ascension day, and eight days after. In 1320 a Tuesday market was granted, but no fair is mentioned. James I. granted a Friday market, and two fairs, at the feast of St. Philip and St. James, and on St. Luke's day. The fair has died out, but markets are still held on Tuesday and Friday. In the 14th century merchants came even from Spain, and there was much trade in wheat and wool with Flanders. But the passenger traffic appears to have been as important at Harwich in the 14th century as it is now. Shipbuilding was a large industry at Harwich in the 17th century.

The town of Harwich occupies an elevated situation, and a wide view is obtained from Beacon hill at the southern end of the esplanade. The harbour is one of the best on the east coast of England, and in stormy weather is largely used for shelter, and ships drawing 17 ft. can enter at low water. A breakwater and seawall prevent the blocking of the harbour entrance and encroachments of the sea; and there is another breakwater at Landguard point on the opposite (Suffolk) shore of the estuary. The principal imports are grain and agricultural produce, timber and coal, fruit, vegetables, cattle and horses and the exports cement, horses and fish. Harwich is one of the principal English ports for continental passenger traffic, steamers regularly serving the Hook of Holland, Amsterdam, Rotterdam, Antwerp, Esbjerg, Zeebrugge, Copenhagen and Hamburg. A train ferry to Zeebrugge was inaugurated in 1924. The continental trains of the L.N.E. railway run to Parkeston quay, 1 m. from Harwich up the Stour, where the passenger steamers start. The fisheries are important, principally those for shrimps and lobsters. There are cement and shipbuilding works. There are several of the Martello towers of the Napoleonic era. Between the Parkeston Quay and Town railway stations is that of Dovercourt, a popular watering-place now united with Harwich. Harwich is the most important naval base on the east coast.

HARZBURG, a town of Germany, in the republic of Brunswick, situated at the northern foot of the Harz mountains, at the terminus of the railway from Brunswick, 5 m. E.S.E. from Goslar and 18 m. S. from Wolfenbüttel. Pop. (1925) 6,198. The town is a spa and possesses brine and carbonated springs. A mile and a half south from the town lies the Burgberg, 1,500 ft. above sea-level, with remains of an old castle and, according to tradition, formerly an altar to the heathen god Krodo, still to be seen in the Ulrich chapel at Goslar.

HARZ MOUNTAINS, the most northerly mountain-system of Germany, situated between the rivers Weser and Elbe, occupy an area of 784 sq.m. Their greatest length extends in a south-east and north-west direction for 57 m. and their maximum breadth is about 20 m. An irregular series of terraced plateaus rises here and there into rounded summits, and is intersected by narrow, deep valleys. The north-western and higher part is Ober or Upper Harz; the south-eastern and more extensive part, Unter or Lower Harz; while the north-west and south-west slopes of the Upper Harz form the Vorharz. The Brocken group, dividing the Upper and Lower Harz, is generally classed with the Upper. The Upper Harz includes the Brocken (3,806 ft.), the Heinrichshöhe (3,425 ft.), the Königsberg (3,376 ft.) and the Wurmberg (3,176 ft.);

the Lower Harz, the Josephshöhe in the Auerberg group and the Viktorshöhe in the Ramberg, each 1,887 ft. The Brocken (*q.v.*) is celebrated in legends immortalized in Goethe's *Faust*. While useful in working the numerous mines of the district, at other parts of their course the many streams present most picturesque scenery. The finest valley is the rocky Bodethal, with the Ross-

trappe, the Hexentanzplatz, the Baumannshöhle and the Bielschöhle.

The Harz is a mass of Palaeozoic rock rising through the Mesozoic strata of north Germany, and bounded on all sides by faults. Slates, schists, quartzites and limestones form the greater part but the Brocken and Viktorshöhe are intrusive granite, and diabases and diabase tuffs are interstratified with sediments. Silurian, Devonian and Carboniferous are represented—the Silurian and Devonian forming the greater part of the hills south-east of a line drawn from Lauterberg to Wernigerode, while north-west of this line the Lower Carboniferous predominates. A few patches of Upper Carboniferous on the borders of the hills near Ilfeld, Ballenstedt, etc., are unconformable upon the Devonian. The general strike of the folds, especially in Oberharz is about north-east. The mass belongs to the Hercynian chain of Europe (which derives its name from the Harz), and continues north-eastwards the Ardennes and Eifel. The folding took place at the close of the Palaeozoic; but the faulting to which they owe their present position was probably Tertiary. Metalliferous veins are common, amongst the best-known being the silver-bearing lead veins of Klausthal, which occur in the Culm or Lower Carboniferous.

Owing to its position as the first range which the northerly winds strike after crossing the north German plain, the climate on the summit of the Harz is generally raw and damp, even in summer. In 1895 an observatory was opened on the top of the Brocken, and the results of the first five years (1896–1900) showed a July mean of 50° Fahr., a February mean of 24.7°, and a yearly

mean of 36.6°. During the same five years the rainfall averaged 64½ in. annually. But while the hill-top summer is thus ungenial, the summer heat of the lower-lying valleys is greatly tempered and cooled; so that, adding this to the scenery, forests and legendary and romantic associations, the Harz is a favourite summer resort. Among the more popular places of resort are Harzburg, Thale and the Bodethal; Blankenburg, with the Teufelsmauer and the Hermannshöhle; Wernigerode, Ilsenburg, Grund, Lautenberg, Hubertusbad, Alexisbad and Suderode. Some places also have mineral springs and baths, pine-needle baths, whey cures, etc. The Harz is penetrated by several railways, among them a rack-railway up the Brocken, opened in 1898.

The northern summits are bare, but the lower slopes of the Upper Harz are rich in pines and firs. Between the forests stretch numerous peat-mosses, the spongy reservoirs of which are sources of many small streams. On the Brocken are found one or two arctic and several alpine plants. In the Lower Harz the forests contain a great variety of timber. The beech attains unusual size and beauty, and the walnut-tree grows in the eastern districts. The last bear was killed in the Harz in 1705, and the last lynx in 1817, and since then the wolf has become extinct; but deer, foxes, wild cats and badgers are still found.

Mining has been carried on since the middle of the 16th century, especially for rich argentiferous lead, but gold in small quantities, copper, iron, sulphur, alum and arsenic are also found. Klausthal and St. Andreasberg in the Upper Harz are the chief centres. Near the latter the Samson shaft goes down 2,790 ft. or 720 ft. below sea-level. For obviating flooding of deep workings, large drainage works have been built. In 1777-1799 the Georgsstollen was cut through the mountains from the east of Klausthal westward to Grund, a distance of 4 m.; the Ernst-Auguststollen, no less than 14 m. in length, was made from the same neighbourhood to Gittelde, at the west side of the Harz, in 1851-1864. Marble, granite and gypsum are worked; and vitriol is manufactured. Much wood is exported for building and other purposes, and it is used locally as fuel. The sawdust of numerous mills is collected for use in paper-making. Turf-cutting, coarse lace-making and the breeding of canaries and native song-birds also occupy many of the people. Agriculture is carried on chiefly on the plateaus of the Lower Harz; but there is excellent pasturage both in the north and in the south. In the Lower Harz, as in Switzerland, the cows, which carry bells are driven up into the heights in early summer, returning to the sheltered regions in late autumn.

Upper and Lower Saxon, Thuringian and Frankish stocks have all contributed to form the present people, and their respective influences are still to be traced in the varieties of dialect. The boundary line between High and Low German passes through the Harz. The Harz was the last stronghold of paganism in Germany, and to that fact are due its legends and fanciful names.

See G. Braun, *Deutschland* (Berlin, 1926).

HASĀ, AL, so-called from the springs of its main oasis, is the easternmost province of the kingdom of Najd or Nejd extending S. along the west coast of the Persian gulf, with an average width of 50 m. from the frontier of the Kuwait enclave to Jabrin on the north edge of the Great South desert. The coast is low and flat, with a deep barrier of sand-dunes between it and the hard desert. Along it are the three ports of Jubail, Qāṭif and 'Uqair (ancient Gerrha), the first and last being fair harbours, which of recent years have attracted an increasing amount of trade, while Qāṭif is both a sea-port and extensive oasis with palms and other cultivation irrigated by springs. The fort of Qāṭif is a strongly-built structure attributed to the Carmathian prince, Abu Tāhīr. Inland the southern oasis of Jabrin was found by Cheesman, in 1923, to be a miserable settlement of palms, the headquarters of the camel-breeding tribe, Al Murra, of the Rub' Al Khālī.

About 150 m. N. lies the main oasis, which gives its name to the province and is famous for its many springs, both hot and cold; its prosperous palm groves producing the excellent Khalās variety of date; its Shiā' population; its peculiar breed of large white donkeys; and its many settlements, of which the chief are Hufūf (30,000) and Mubarrāz (20,000). The Kūt or fort of

Hufūf is attributed to the Carmathians, and its chief architectural feature is the great mosque of Ibrāhīm Pasha, so named after a Turkish governor of the province (not the famous Ibrāhīm Pasha) during the early 19th century. The great market place, or Sūq al Khamīs, is the scene of great activity every Thursday, when a good business is done in the produce of the oasis and the 'abas (mantles) and leather-work, which are the main features of local industry. 'Ain al Hārā, near Mubarrāz, and Umm al Saba' are the most remarkable of the numerous spring-fed pools, from which perennial streams issue for the irrigation of the oasis.

Before the Wahhābī movement of the 18th century, Hasā was ruled by princes of a dynasty called 'Aair. In due course it was absorbed by the Wahhābī empire and, on the destruction of the latter, it came within the orbit of Turkey. Relapsing again under the Wahhābī rule of Faisal ibn Sa'ūd, it was reoccupied in 1875 by Midhat Pasha and remained part of the Turkish province of Najd until 1914, when Abdul'aziz ibn Sa'ūd captured it by a bold *coup-de-main* and ejected the Turkish garrisons from Hufūf, Qāṭif and 'Uqair. Since then the province has enjoyed a period of peace and growing prosperity, as testified by several British visitors, the last of whom, Cheesman, spent a considerable time at Hufūf and completed the rough survey which was made in 1920 by Maj. H. R. P. Dickson. The Hasā tribes—'Ajman, Banī Hājir and Banī Khālid—were formerly conspicuous disturbers of the peace, but have been brought under effective control by the present governor, appointed to the post in 1914. The peninsula of Qatar, closing the Gulf of Bahrain on the south, forms geographically part of Hasā, but is administered semi-independently by its Shaikhly family of Ibn Thānī, which acknowledges Ibn Sa'ūd as its suzerain. Part of the prosperity of the Hasā is due to its share in the pearl fisheries along its coast. (H. St. J. B. P.)

HASAN and ḤOSAIN (or ḤUSEIN), sons of the fourth Mohammedan caliph Ali by his wife Fatima, daughter of Mohammed. On Ali's death Ḥasan was proclaimed caliph, but the strength of Moawiya who had rebelled against Ali was such that he resigned his claim on condition that he should have the disposal of the treasure stored at Kufa, with the revenues of Darabjird. This secret negotiation came to the ears of Ḥasan's supporters, a mutiny broke out and Ḥasan was wounded. He retired to Medina where he died about 669. The story that he was poisoned at Moawiya's instigation is generally discredited (see CALIPHATE). Subsequently his brother Ḥosain revolted against Moawiya's successor Yazid, but was defeated and killed at Kerbela on Oct. 10, 680. Ḥosain is the hero of the passion play performed annually (e.g., at Kerbela) on the anniversary of his death by the Shi'ites of Persia and India, to whom the family of Ali are the only true descendants of Mohammed.

See Sir Wm. Muir, *The Caliphate* (1883); Sir Lewis Pelly, *The Miracle Play of Hasan and Hosein* (1879).

HASAN UL-BASRI (Abū Sa'ūd ul-Ḥasan ibn Abī-l-Ḥasan Yassār ul-Baṣrī) (642-728 or 737), Arabian theologian, was born at Medina, the son of a freedman of Zaid ibn Thābit, one of the *Anṣār* (Helpers of the Prophet). He became a teacher of Baṣra and founded a school there, where among his pupils was Wāṣil ibn 'Atā, the founder of the Mo'tazilites. He himself was a great supporter of orthodoxy and practised asceticism. With him fear is the basis of morality, and sadness the characteristic of his religion. In politics he adhered to the earliest principles of Islam, being strictly opposed to the inherited caliphate of the Omayyads and a believer in the election of the caliph.

His life is given in Nawāwī's *Biographical Dictionary* (ed. F. Wüstenfeld, Göttingen, 1842-47). Cf. R. Dozy, *Essai sur l'histoire de l'islamisme* (1879); A. von Kremer, *Culturgeschichtliche Streifzüge* (1873); R. A. Nicholson, *A Literary History of the Arabs* (1907).

HASBEYA, a small Druse town of the Beka', situated at the foot of Mt. Hermon, 36 m. W. of Damascus and set in the midst of olives, vines and other fruit trees. Its castle was held by the Crusaders but recaptured by the Druses (1171).

In the immediate neighbourhood is the chief sanctuary of the Druses and the place where the founder of the sect dwelt. A large

number of Christians were massacred here in 1860. In the course of the punitive expedition the sacred and secret books of the Druses were discovered. The ground around Hasbeya is volcanic and there are bitumen pits in the neighbourhood. An identification of the site with the Baal-Gad or Baal-Hermon of the Bible has been suggested. (E. Ro.)

HASDAI IBN SHAPRUT (c. 915–970/90), the founder of the new culture of the Jews in Moorish Spain in the 10th century, was born at Jaen and died at Córdoba. He was both physician and minister to Caliph Abd ar-Rahman III. in Córdoba. A man of wide learning and culture, he encouraged the settlement of Jewish scholars in Andalusia, and promoted the Jewish renaissance in Europe.

See article in *Jewish Encyclopedia*.

HASDEU or **HÄJDEU**, **BOGDAN PETRICEICU** (1836–1907), Rumanian philologist, was born at Khotin, Bessarabia, and studied at the University of Kharkov. In 1858 he first settled in Jassy as professor of the high school and librarian. He may be considered as the pioneer in many branches of Rumanian philology and history. At Jassy he started his *Archiva historica a Romaniei* (1865–67), in which a large number of old documents in Slavonic and Rumanian were published for the first time. In 1870 he inaugurated *Columna lui Traian*, the best philological review of the time in Rumania. In his *Cuvente den Bătrâni* (2 vols., 1878–81) he was the first to contribute to the history of apocryphal literature in Rumania. His *Historia critica a Romanilor* (1875), though incomplete, marks the beginning of critical investigation into the history of Rumania. Hasdeu edited the ancient Psalter of Coresi of 1577 (*Psaltirea lui Coresi*, 1881). In 1876 he was appointed director of the State archives in Bucharest and in 1878 professor of philology at the University of Bucharest. His works include one drama, *Rasvan și Vidra*. After the death of his only child Julia in 1888 he became a mystic and a strong believer in spiritualism. He died at Campina on Sept. 7, 1907. (M. G.)

HASDRUBAL, the name of several Carthaginian generals, the most important being:

1. The son-in-law of Hamilcar Barca (q.v.), who followed the latter in his campaign against the governing aristocracy at Carthage at the close of the First Punic War, and in his subsequent wars in Spain. After Hamilcar's death (228) Hasdrubal, who succeeded him in the command, extended the newly acquired empire by skilful diplomacy, and consolidated it by the foundation of New Carthage (Cartagena) as the capital of the new province, and by a treaty with Rome which fixed the Ebro as the boundary between the two powers. In 221 he was killed by an assassin.

Polybius ii. 1; Livy xxi. 1; Appian, *Hispanica*, 4–8.

2. The second son of Hamilcar Barca, and younger brother of Hannibal. Left in command of Spain when Hannibal departed to Italy (218), he fought for six years against the brothers Gnaeus and Publius Scipio. A defeat in 216 prevented him from joining Hannibal in Italy at a critical moment; but in 212 he completely routed his opponents, both the Scipios being killed. He was subsequently outgeneralled by Publius Scipio the Younger, who in 209 captured New Carthage. Nevertheless, he evaded Scipio and broke into Central Italy (207). He was ultimately defeated on the banks of the Metaurus, his head being thrown into Hannibal's camp by order of the Roman general Nero.

Polybius x. 34–xi. 3; Livy xxvii. 1–51; Appian, *Bellum Hannibalicum*, ch. lii. sqq.; R. Oehler, *Der letzte Feldzug des Barkiden Hasdrubals* (1897); C. Lehmann, *Die Angriffe der drei Barkiden auf Italien* (Leipzig, 1905). See also PUNIC WARS.

HASE, CARL BENEDICT (1780–1864), French Hellenist, of German extraction, was born at Sulza near Naumburg on May 11, 1780, and died in Paris on March 21, 1864. He made his way to Paris on foot in 1801, and from being employed to edit Johannes Lydus by Choiseul-Gouffier, devoted himself to Byzantine studies. In addition to various professorships, in 1812 he was chosen to supervise the studies of Louis Napoleon and his brother. His most important works are the editions of Leo Diaconus and other Byzantine writers (1819), and of Johannes Lydus, *De ostentis* (1823), a masterpiece of textual restoration, the difficulties of which were aggravated by the fact that the ms. had

for a long time been stowed away in a wine-barrel in a monastery.

See J. D. Guignaut, *Notice historique sur la vie et les travaux de Carl Benedict Hase* (1867); articles in *Nouvelle Biographie générale* and *Allgemeine deutsche Biographie*; and a collection of autobiographical letters, *Briefe von der Wanderung und aus Paris*, edited by O. Heine (1894), containing a vivid account of Hase's journey, his enthusiastic impressions of Paris and the hardships of his early life.

HASE, KARL AUGUST VON (1800–1890), German Protestant theologian and Church historian, was born at Steinbach, Saxony on Aug. 25, 1800. He studied at Leipzig and Erlangen, and was professor of theology at Jena from 1829 to 1883. He died at Jena on Jan. 3, 1890. Hase's aim was to reconcile modern culture with historical Christianity in a scientific way. His views are presented scientifically in his *Evangelisch-protestantische Dogmatik* (1826; 6th ed., 1870), the value of which "lies partly in the full and judiciously chosen historical materials prefixed to each dogma, and partly in the skill, caution and tact with which the permanent religious significance of various dogmas is discussed" (Otto Pfeiderer). More popular in style is his *Gnosis oder prot.-evang. Glaubenslehre* (3 vols., 1827–29; 2nd ed., 1869–70). But his reputation rests chiefly on his treatment of Church history in his *Kirchengeschichte, Lehrbuch zunächst für akademische Vorlesungen* (1834, 12th ed.; 1900).

For his life see his *Ideale und Irrtümer* (1872; 5th ed., 1894) and *Annalen meines Lebens* (1891); R. Bürkner, *Karl von Hase* (1900). See also O. Pfeiderer, *Development of Theology* (1890); F. Lichtenberger, *Hist. of German Theology* (1889).

HASHISH or **HASHEESH**, the Arabic name, meaning literally "dried herb," for the various preparations of the Indian hemp plant (*Cannabis indica*), used as a narcotic or intoxicant in the East, and either smoked, chewed, or drunk (see **HEMP** and **BHANG**). From the Arabic hashishin, i.e., "hemp-eaters," comes the English "assassin" (see **ASSASSIN**).

HASKOVO, a town in S. Bulgaria, capital of the department of the same name. Pop. (1926) 26,366. It is connected by rail with the main Sofia-Constantinople railway. It is an important centre for the tobacco trade of S. Bulgaria. Near by are a natural mineral bath and a coal mine.

HASLEMERE, a market-town in Surrey, England, 43 m. S.W. from London by the S.R. It is situated in an elevated valley between the ridges of Hindhead (895 ft.) and Blackdown (918 ft.). Their summits are open heath, but their flanks are wooded and deeply scored by steep valleys, of which the most remarkable is the Devil's Punch Bowl, a hollow on the west flank of Hindhead. On Blackdown is Aldworth, built for Alfred, Lord Tennyson, who died here in 1892. George Eliot stayed for a considerable period at Shottersmill, a neighbouring village. Pop. of Haslemere (1921) 3,865; of Hindhead, 1,536.

HASLER or **HASSLER, HANS LEO** (?1564–1612), German composer, was born at Nuremberg, probably in 1564. He was taught by his father, Isaac Hasler, a musician of some standing in Nuremberg, and afterwards became a pupil of Andrea Gabrieli in Venice. About 1585 he entered the house of the Fuggers at Augsburg and in 1560 was appointed musical director in that city. He next became organist of the Frauenkirche at Nuremberg (1601) and in 1608 entered the service of Christian II. of Saxony. He died on June 8, 1612, at Frankfurt. Hasler is considered the greatest German representative of the Venetian school. His church music is of great beauty but his fame rests on the charm of his secular "songs," which are essentially German in spirit. One of his melodies in the *Lustgarten deutscher Gesänge*: "Mein G'müt ist mir verwirret, das macht ein' Jungfrau zart" was adapted to the chorales "Herzlich tut mich verlangen," "O Haupt voll Blut und Wunden" and others, and appears no fewer than five times in Bach's Matthew Passion.

Hasler's principal works are: *XXIV. Canzonetti a 4 voci* (Nuremberg 1590); *Cantiones sacrae de festis praecipuis totius anni 4, 5, 8, et plurimum vocum* (Augsburg, 1591); *Concentus ecclesiastici* (Augsburg 1596); *Neue teutsche Gesaeng, Madrigali* (1596); *Cantiones novae* (1597); *8 Masses* (1599); *Lustgarten deutscher Gesänge* (1601, reprinted in *Ges. d. Musikforschung's* publications) *Sacri concentus*, 5 to 13 v. (Augsburg 1601) *Psalmen u. Gesänge* (Nuremberg 1607, Breitkopf 1777); German and Latin secular songs. Three masses are included in Proske's *Musica divina*, a *Pater noster* in Rochlitz's *Sammlung* vol.

III. and other pieces in Bodenschatz's *Florilegium* and Schadaeus's *Promptuarium musicum*. See Eitner: *Quellenlexikon* and a bibl. in *Monatshefte für Musikgeschichte* (1874).

HASLINGDEN, market town, municipal borough, Rossendale parliamentary borough, Lancashire, England, 19 m. N.W. of Manchester by the L.M.S. railway. Pop. (1921) 17,486. The old town stood on the slope of a hill, on the borders of Rossendale forest, but the modern part has extended about its base. The parish church of St. James (rebuilt 1780), still retains a 16th century tower. Woollen manufactures have given place to the manufacture of cotton goods. Engineering works, coal mining, quarrying and brick making are carried on in the neighbourhood. The borough was incorporated in 1891.

HASPE, a town in the Prussian province of Westphalia, on the Düsseldorf-Dortmund railway 10 m. N.E. of Barmen, was raised to the rank of a town in 1873. Pop. (1925) 25,636. Its industries include iron foundries, rolling mills, puddling furnaces and manufactures of iron, steel, brass, aluminium wares and of machines.

HASSAM, CHILDE (1859–), American figure and landscape painter and etcher, was born in Dorchester, now part of the city of Boston, and studied in Boston and Paris. He soon fell under the influence of the Impressionists, and took to painting in a style of his own, in brilliant colour, with effective touches of pure pigment. He won a bronze medal at the Paris Exhibition of 1889; medals at the World's Fair, Chicago, 1893; Boston Art Club, 1896; Philadelphia Art Club, 1892; Carnegie Institute, Pittsburgh, 1898; Buffalo Pan-American, 1901; Temple gold medal, Pennsylvania Academy of Fine Arts, Philadelphia, 1899; silver medal, Paris Exhibition, 1900; and gold medal of honour, Pennsylvania Academy of Fine Arts, 1920; and a gold medal at the Sesqui-centennial Exhibition, Philadelphia, 1926.

HASSAN, a town and district of Mysore, India. The town dates from the 11th century and had in 1921 a population of 8,096. The district naturally divides into the Malnad, or hill country, including some of the highest ranges of the Western Ghats, and the Maidan or plain country, sloping towards the south. The Hemavati, which flows into the Cauvery in the extreme south, is the most important river. The upper slopes of the Western Ghats are clothed with forests, and wild animals abound. Minerals found are gold, magnesite, mica, corundum and asbestos. The soil of the valleys is rich red loam. The area is 2,665 sq.m. Population (1921) 583,960. The district contains remarkable monuments, such as the colossal Jain image at Sravana Belgola (a monolith 57 ft. high on the summit of a hill) and the great temple at Halebid. Coffee cultivation is largely carried on. The Madras and Southern Mahratta railway traverses the north-east of the district, and Hassan has a station on the line of the Mysore railway from Arsikere to Mysore.

The history of Hassan begins with the Hoysala dynasty, which lasted from the 11th till the 14th century. Their capital was at Dwarasamundra (Dwaravati-pura), the ruins of which are scattered round the village of Halebid. The earlier kings professed the Jain faith, but the finest temples were erected to Siva by later monarchs. At their zenith all south India owned their sway.

HASSANIA, an African tribe of Arab stock. They inhabit the desert between Merawi and the Nile at the 6th cataract, and the left bank of the Blue Nile immediately south of Khartum. See H. A. MacMichael, *History of the Arabs of the Sudan* (1922).

HASSÂN IBN THÂBIT (died 674), Arabian poet, was born in Yathrib (Medina), a member of the tribe Khazraj. In his youth he travelled to Hira and Damascus, then settled in Medina, where, after the advent of Mohammed, he accepted Islam and wrote poems in defence of the prophet. His poetry is regarded as lacking in distinction.

His diwan has been published at Bombay (1864), Tunis (1864) and Lahore (1878). See H. Hirschfeld's "Prolegomena to an edition of the Diwan of Hassan" in *Transactions of Oriental Congress* (1892).

(G. W. T.)

HASSE, JOHANN ADOLPH (1699–1783), German musical composer, was born at Bergedorf near Hamburg, on March 25, 1699. After singing in a travelling operatic company and at the court theatre of Brunswick, he made his début as a composer

at that theatre with the opera *Antigonus*. Afterwards he went to Italy to complete his studies under Porpora, with whom, however, he seems to have disagreed both as a man and as an artist. But he gained the friendship of Alessandro Scarlatti, to whom he owed his first commission for a serenade for two voices, sung by two of the greatest singers of Italy, Farinelli and Signora Tesi. Subsequently his opera *Sesostrato*, written for the Royal Opera at Naples in 1726, made his name known all over Italy. He then spent some years in Venice, where he married (1730) the soprano singer Faustina Bordogni (1693–1783) with whom he was invited by the splendour-loving elector of Saxony, Augustus II. In 1733 Hasse was invited to London by the aristocratic clique inimical to Handel. But he modestly and wisely declined to become the great master's rival, remaining in London only long enough to superintend the rehearsals for his opera *Artaserse* (first produced at Venice, 1730). Meanwhile Faustina had remained at Dresden, the declared favourite of the public and unfortunately also of the elector; her husband, who remained attached to her was only allowed to see her at long intervals. In 1739, after the death of Augustus II., Hasse settled permanently at Dresden till 1763, when he and his wife retired from court service. Later, however, he went with his family to Vienna, and added several operas to the great number of his works already in existence. His last work for the stage was the opera *Ruggiero* (1771), written for the wedding of Archduke Ferdinand at Milan. On the same occasion a work by Mozart, then fourteen years old, was performed, and Hasse observed "this youngster will surpass us all." Hasse died at Venice on Dec. 23, 1783.

His compositions include 120 operas, besides oratorios, cantatas, masses, and many instrumental works, all now forgotten though the popularity which many of them enjoyed during the composer's life time was enormous. The two airs which Farinelli had to repeat every day for ten years to the melancholy king of Spain, Philip V., were both from Hasse's works.

HASSELT, ANDRE HENRI CONSTANT VAN (1806–1874), Belgian poet, was born at Maastricht, in Limburg, on Jan. 5, 1806. He was educated in his native town, and at the University of Liège. In 1833 he left Maastricht, then blockaded by the Belgian forces, and made his way to Brussels, where he became a naturalized Belgian, and was attached to the Bibliothèque de Bourgogne. In 1843 he entered the education department, and eventually became an inspector of normal schools. His native language was Dutch, and as a French poet André van Hasselt had to overcome the difficulties of writing in a foreign language. His first volume of verse, *Primevères* (1834), shows markedly the influence of Victor Hugo, which had been strengthened by a visit to Paris in 1830. His relations with Hugo became intimate in 1851–52, when the poet was an exile in Brussels. His chief work, the epic of the *Quatre Incarnations du Christ*, was published in 1867. In the same volume were printed his *Études rythmiques*, a series of metrical experiments designed to show that the French language could be adapted to every kind of musical rhythm. He died in Dec. 1874.

A selection from his works (10 vols., 1876–77) was edited by Charles Hen and Louis Alvin. He wrote many books for children, chiefly under the pseudonym of Alfred Avelines; and studies on historical and literary subjects. The books written in collaboration with Charles Hen are signed Charles André. A bibliography of his writings is appended to the notice by Louis Alvin in the *Biographie nat. de Belgique*, vol. vii. A series of tributes to his memory are printed in the *Poésies choisies* (1901), edited by Georges Barral for the *Collection des poètes français de l'étranger*. This book contains a biographical and critical study by Jules Guillaume, and some valuable notes on the poet's theories of rhythm.

HASSELT, the capital of the Belgian province of Limburg. Pop. (1925) 21,166. It stands at the junction of several important roads and railways from Maaseyck, Maastricht and Liège. It has many breweries and distilleries, and makes coarse gin called Hasselt spirit. On Aug. 6, 1831 the Dutch troops obtained here their chief success over the Belgian nationalists during the War of Independence. A septennial fete is held on the day of Assumption, Aug. 15, in honour of the Virgin under the name of Virga Jesse. Fir trees and branches are planted in front of the houses. The figure of the giant who is supposed to have once held the

Hazelbosch under his terror is paraded on this occasion as the "lounge man." Originally this celebration was held annually, but in the 18th century it was restricted to once in seven years. Hasselt is beginning to grow quickly as the industrial capital of the new Campini coalfield.

HASSENPFUG, HANS DANIEL LUDWIG FRIEDRICH (1794–1862), German statesman, was born at Hanau, Hesse, on Feb. 26, 1794. He studied law at Göttingen, graduated in 1816, and took his seat as *Assessor* in the judicial chamber of the board of government (*Regierungskollegium*) at Cassel, of which his father Johann Hassenpflug was also a member. He rose rapidly, and in May 1832 was appointed successively minister of justice and of the interior. He now became conspicuous in the constitutional struggles of Germany. He deliberately set to work to reverse the Hessian constitution of 1831. The story of the constitutional deadlock that resulted belongs to the history of Hesse-Cassel and Germany; so far as Hassenpflug himself was concerned, it made him, more even than Metternich, the Mephistopheles of the Reaction to the German people. In the summer of 1837 he was suddenly removed from his post as minister of the interior and he thereupon left the elector's service.

In 1838–39 he was head of the administration of the little principality of Hohenzollern-Sigmaringen, and in 1839–40 civil governor of the grand-duchy of Luxemburg. From 1841 to 1850 he was in the Prussian judicial service. In 1850 he was tried for peculation and convicted; and, though this judgment was reversed on appeal, he left the service of Prussia.

He was now recalled by the elector of Hesse, and immediately threw himself again with zeal into the struggle against the constitution. Finding the opinion of all classes, including the army, solidly against him, he decided to risk all on an alliance with the reviving fortunes of Austria, which was steadily working for the restoration of the *status quo* overthrown by the revolution of 1848. On his advice the elector seceded from the Northern Union established by Prussia and, on Sept. 13 fled from Hesse with his minister. They went to Frankfort, where the federal diet had been re-established, and on the 21st persuaded the diet to decree armed intervention in Hesse. This decree, carried out by Austrian troops, all but led to war with Prussia, but the unreadiness of the Berlin government led to the triumph of Austria and of Hassenpflug, who at the end of the year was installed at Cassel as minister of finance. He was loathed and despised by all, and disliked even by his master. In November 1853, he was publicly horse-whipped by the count of Isenburg-Wächtersbach, the elector's son-in-law. The count was pronounced insane; but Hassenpflug tendered his resignation. It was not accepted; and it was not till Oct. 16, 1855 that he was finally relieved of his offices. He died at Marburg on Oct. 16, 1862. He lived just long enough to hear of the restoration of the Hesse constitution of 1831 (June 21, 1862), which it had been his life's mission to destroy. Of his publications the most important is *Actenstücke, die landständischen Anklagen wider den Kurfürstlichen hessischen Staatsminister Hassenpflug. Ein Beitrag zur Zeitgeschichte und zum neueren deutschen Staatsrechte*, anonym. (Stuttgart and Tübingen, 1836.) He was twice married, his first wife being the sister of the brothers Grimm.

See the biography by Wippermann in *Allgemeine deutsche Biographie*, with authorities.

HASTINAPUR, an ancient city of British India, in the Meerut district of the United Provinces, lying on the banks of a former bed of the Ganges, 22 m. N.E. of Meerut. It formed the capital of the great Pandava kingdom, celebrated in the *Mahābhārata*, and probably one of the earliest Aryan settlements outside the Punjab. Tradition points to a group of shapeless mounds as the residence of the Lunar princes of the house of Bharata whose deeds are commemorated in the great national epic. The town was finally swept away by a flood of the Ganges, and the capital was transferred to Kausambi.

HASTINGS, a famous English family. Sir Henry de Hastings (d. 1268), was summoned to parliament as a baron by Simon de Montfort in 1264. Having joined Montfort's party Sir Henry led the Londoners at the battle of Lewes and was taken prisoner

at Evesham. He was among those who resisted the king at Kenilworth, and after the issue of the *Dictum de Kenilworth* he commanded the remnants of the baronial party when they made their last stand in the isle of Ely, submitting to Henry in July 1267.

His son JOHN, BARON HASTINGS (c. 1262–c. 1313), married Isabella (d. 1305), daughter of William de Valence, earl of Pembroke, a half-brother of Henry III. His paternal grandmother, Ada, was a younger daughter of David, earl of Huntingdon, and a niece of the Scottish king, William the Lion; and in 1290 when Margaret, the maid of Norway, died, Hastings came forward, unsuccessfully, as a claimant for the vacant throne. He fought constantly either in France or in Scotland; he led the bishop of Durham's men at the celebrated siege of Carlaverock castle in 1300; and with his brother Edmund he signed the letter which in 1301 the English barons sent to Pope Boniface VIII. repudiating papal interference in the affairs of Scotland; on two occasions he represented the king in Aquitaine.

LAURENCE HASTINGS (1318?–1348), son of John, 3rd baron, was created earl of Pembroke in 1339. (See PEMROKE.)

HASTINGS, FRANCIS RAWDON-HASTINGS, 1ST MARQUESS OF (1754–1826), British soldier and governor-general of India, born on Dec. 9, 1754, was the son of Sir John Rawdon of Moira, Co. Down, fourth baronet, who was created Baron Rawdon of Moira, and afterwards earl of Moira, in the Irish peerage. Lord Rawdon, as he was then called, was educated at Harrow and Oxford, and joined the army in 1771 as ensign in the 15th foot. His life may be divided into four periods: from 1775 to 1782 he was engaged with much distinction in the American war; from 1783 to 1813 he held various high appointments at home, and took an active part in the business of the House of Lords; from 1813 to 1823 was the period of his labours in India; after retiring from which, in the last years of his life (1824–1826), he was governor of Malta. He was created an English peer, Baron Rawdon (1783), and succeeded his father as earl of Moira in 1793.

In 1812 he was appointed governor-general of Bengal and commander-in-chief of the forces in India. He landed at Calcutta, and assumed office in succession to Lord Minto in Oct. 1813. One of the chief questions which awaited him was that of relations with the Gurkha state of Nepal. Lord Moira, after travelling through the northern provinces to study the question, declared war against Nepal (Nov. 1814). The enemy's frontier was 600 m. long, and Lord Moira, who directed the plan of the campaign, resolved to act offensively along the whole line. In 1816 the Gurkhas abandoned the disputed districts, ceded some territory to the British, and agreed to receive a British resident. This affair brought Lord Moira the marquessate of Hastings (1817).

He had now to deal with a combination of Mahratta powers. In 1816 the Pindaris entered British territory in the Northern Circars, where they destroyed 339 villages. Before the end of 1817 the preparations of Lord Hastings were completed, when the peshwa suddenly broke into war, and the British were opposed at once to the Mahratta and Pindari powers, estimated at 200,000 men and 500 guns. Both were utterly shattered in a brief campaign of four months (1817–18). The peshwa's dominions were annexed, and those of Sindhia, Holkar, and the raja of Berar lay at the mercy of the governor-general, and were saved only by his moderation. Thus, after 60 years from the battle of Plassey, the supremacy of British power in India was effectively established.

While Lord Hastings's achievements were appreciated in India, the court of directors of the East India company grumbled at his having extended British territory. They also disliked his measures for introducing education among the natives and his encouraging the freedom of the press. In 1819 he obtained the cession by purchase of the island of Singapore. In finance his administration was very successful, as, in spite of his wars, he showed an annual surplus of two millions sterling. Lord Hastings did not escape unjust detraction. His last years of office were embittered by the discussions on the affairs of the banking-house of W. Palmer and company. Annoyed by the insinuations made against him, he tendered his resignation in 1821, though he did not leave India till the first day of 1823. He was much exhausted by his nine years

of labour in India, and his fortune was gone. In 1824 he received the comparatively small post of governor of Malta. He died on Nov. 28, 1826, leaving a request that his right hand should be cut off and preserved till the death of the marchioness of Hastings, and then be interred in her coffin.

See Ross-of-Bladensburg, *The Marquess of Hastings* ("Rulers of India" series, 1893); and *Private Journal of the Marquess of Hastings*, edited by his daughter, the marchioness of Bute (1858).

HASTINGS, FRANK ABNEY (1794-1828), British naval officer and phil-Hellene, was son of Lieut.-gen. Sir Charles Hastings, a natural son of Francis Hastings, tenth earl of Huntingdon. He served in the navy from 1805 to 1820. In 1822 he joined the Greek service. For two years he took part in the naval operations in the Gulf of Smyrna and elsewhere. He saw that the light squadrons of the Greeks must in the end be overpowered by the heavier Turkish navy, clumsy as it was; and in 1823 he drew up and presented to Lord Byron an able memorandum which was laid before the Greek Government in 1824. This paper contains the germs of the great revolution afterwards effected in naval gunnery and tactics. In substance the memorandum advocated the use of steamers in preference to sailing ships, and of direct fire with shells and hot shot, as a more trustworthy means of destroying the Turkish fleet than fire-ships.

The application of Hastings's ideas led necessarily to the disuse of sailing ships, and the introduction of armour. Largely by the use of his own money, of which he is said to have spent £7,000, he was able to some extent to carry out his bold plans. In 1824 he came to England to obtain a steamer, and in 1825 he had fitted out a small steamer named the "Karteria" (Perseverance), manned by Englishmen, Swedes and Greeks, and provided with apparatus for the discharge of shell and hot shot. The effect produced by his shells in an attack on the sea-line of communication of the Turkish army, then besieging Athens at Oropus and Volo in March and April 1827, proved the truth of his contention. After the defeat of the Greeks round Athens, Hastings, in co-operation with General Sir R. Church (*q.v.*), shifted the scene of the attack to western Greece. Here his destruction of a small Turkish squadron at Salona Bay in the Gulf of Corinth (Sept. 29, 1827) provoked Ibrahim Pasha into the aggressive movements which led to the destruction of his fleet by the allies at Navarino (*q.v.*) on Oct. 20, 1827. On May 25, 1828, Hastings was wounded in an attack on Anatolikon, and he died in the harbour of Zante on June 1.

See T. Gordon, *History of the Greek Revolution* (1832); G. Finlay, *History of the Greek Revolution* (Edinburgh, 1861).

HASTINGS, WARREN (1732-1818), the first governor-general of British India, was born on Dec. 6, 1732, in the hamlet of Churchill, near Daylesford, of an old Oxfordshire family which had fallen into poverty. His mother died a few days after giving him birth; his father, Pynaston Hastings, drifted away to perish obscurely in the West Indies. Young Hastings attended a charity school in his native village until, at the age of eight, he was taken in charge by an uncle, Howard Hastings, who held a post in the customs. After two years at a private school at Newington Butts, he was sent to Westminster, where Thurlow, Shelburne, Elijah Impey, and the poets Cowper and Churchill were among his contemporaries. In 1749, his uncle died, leaving him to the care of a distant kinsman, Mr. Creswicke, who sent his ward to seek his fortune as a "writer" in Bengal.

When Hastings landed at Calcutta in October 1750 the affairs of the East India Company were at a low ebb. In southern India French influence was predominant. Bengal, however, was under the able government of Ali Vardi Khan, who peremptorily forbade the foreign settlers at Calcutta and Chandernagore to introduce feuds from Europe. Hastings was placed in charge of an *aurang* or factory in the interior, where his duties would be to superintend the weaving of silk and cotton goods under a system of money advances. In 1753 he was transferred to Cossimbazar, the river-port of the native capital of Murshidabad. In 1756 the old nawab died, and was succeeded by his grandson Suraj-ud-Dowla, a young madman of 19, whose name is indelibly associated with the tragedy of the Black Hole. When Suraj-ud-

Dowla resolved to drive the English out of Bengal, his first step was to occupy the fortified factory at Cossimbazar, and imprison Hastings and his companions. Hastings was soon released at the intercession of the Dutch resident, and made use of his position at Murshidabad to open negotiations with the English fugitives at Falta, the site of a Dutch factory near the mouth of the Hugli. After a while he fled from the Mohammedan court to join the main body of the English at Falta.

When the relieving force arrived from Madras under Colonel Clive and Admiral Watson, Hastings enrolled himself as a volunteer, and took part in the action which led to the recovery of Calcutta. Clive appointed him in 1758 resident at the court of Murshidabad. There he first came into collision with the Bengali Brahman, Nuncomar. During his three years of office as resident he served the Company well, but his name nowhere occurs in the official lists of those who derived pecuniary profit from the necessities and weakness of the native court. In 1761 he was promoted to be member of council, under the presidency of Vansittart, who had been introduced by Clive from Madras. The period of Vansittart's government has been truly described as "the most revolting page of our Indian history." The administration was left in the hands of the nawab, while a few irresponsible English traders had drawn to themselves all real power. The members of council, the commanders of the troops, and the commercial residents plundered on a grand scale. The youngest servant of the Company claimed the right of trading on his own account, free from taxation and from local jurisdiction, not only for himself but also for every native subordinate whom he might permit to use his name.

This exemption, threatening the very foundations of the Muslim government, finally led to a rupture with the nawab. Sometimes in conjunction only with Vansittart, sometimes absolutely alone, Hastings protested unceasingly against the policy and practices of his colleagues. On one occasion he was stigmatized in a minute by Batson with "having espoused the nawab's cause, and as a hired solicitor defended all his actions, however dishonourable and detrimental to the Company." An altercation ensued. Batson gave him the lie and struck him in the council chamber. When war was actually begun, Hastings officially recorded his previous resolution to have resigned, in order to repudiate responsibility for measures which he had always opposed. After the decisive victory of Buxar over the allied forces of Bengal and Oudh, he resigned his seat and sailed for England in November 1764.

Fourteen years' residence in Bengal had not made Hastings a rich man, estimated by the opportunities of his position. According to the custom of the time he had augmented his slender salary by private trade. At a later date he was charged by Burke with having taken up profitable contracts for supplying bullocks for the use of the Company's troops. It is admitted that he conducted by means of agents a large business in timber in the Gangetic Sundarbans. When at Falta he had married Mrs. Buchanan, the widow of an officer. She bore him two children, of whom one died in infancy at Murshidabad, and was shortly followed by her mother (1759). The other child, a son, was sent to England, and also died shortly before his father's return. While at home Hastings made the personal acquaintance of Samuel Johnson and Lord Mansfield. In 1766 he was called upon to give evidence before a committee of the House of Commons upon the affairs of Bengal.

In the winter of 1768, Hastings received the appointment of second in council at Madras. Among his companions on his voyage round the Cape were the Baron Imhoff, a speculative portrait-painter, and his wife, a lady of some personal attractions and great social charm, who was destined henceforth to be Hastings's lifelong companion. At Madras he won the good-will of his employers by devoting himself to the improvement of their manufacturing business, and he kept his hands clean from the prevalent taint of pecuniary transactions with the nawab of the Carnatic. He drew up a scheme for the construction of a pier at Madras, to avoid the dangers of landing through the surf, and instructed his brother-in-law in England to obtain estimates from the engineers Brindley and Smeaton.

In 1772 he was nominated to the second place in council in Bengal with a promise of the reversion of the governorship when Mr. Cartier should retire. The second governorship of Clive was marked by the transfer of the *divāni* or financial administration from the Mogul emperor to the Company, and by the enforcement of stringent regulations against the besetting sin of peculation. But Clive was followed by two inefficient successors; and in 1770 occurred the most terrible Indian famine on record, which is credibly estimated to have swept away one-third of the population. In April 1772 Warren Hastings took his seat as president of the council at Fort William. His first care was to effect a radical reform in the system of government. Clive's plan of governing through the agency of the native court had proved a failure. The directors were determined "to stand forth as *divān*, and take upon themselves by their own servants the entire management of the revenues." All the officers of administration were transferred from Murshidabad to Calcutta, which Hastings boasted at this early date that he would make the first city in Asia.

This reform involved the ruin of many native reputations, and for a second time brought Hastings into collision with Nuncomar. At the same time a settlement of the land revenue on leases for five years was begun, and the police and military systems of the country were placed upon a new footing. Hastings was a man of immense industry, with an insatiable appetite for detail. The whole of this large series of reforms was conducted under his own personal supervision. As a measure of economy, the stipend paid to the titular nawab of Bengal, who was then a minor, was reduced by one-half—to sixteen *lakhs* a year (say £160,000). Macaulay imputes this reduction to Hastings as a characteristic act of financial immorality; but it had been expressly enjoined by the court of directors, in a despatch dated six months before Hastings took up office. His bargains with Shuja-ud-Dowlah, the nawab wazir of Oudh, stand on a different basis. The Mahrattas had got possession of the person of the Mogul emperor, Shah Alam, from whom Clive obtained the grant of Bengal in 1765, and to whom he assigned in return the districts of Allahabad and Kora and a tribute of £300,000.

With the emperor in their camp, the Mahrattas were threatening the province of Oudh. Hastings, as a deliberate measure of policy, withheld the tribute due to the emperor, and resold Allahabad and Kora to the wazir of Oudh. The Mahrattas retreated, and danger for the time was dissipated by the death of their principal leader. The wazir now determined to satisfy an old quarrel against the adjoining tribe of Rohillas, who had established themselves for some generations in a fertile tract west of Oudh. They were not so much the occupiers of the soil as a dominant caste of warriors and freebooters. But in those troubled days their title was as good as any to be found in India. After some hesitation, Hastings allowed the Company's troops to be used to further the designs of his Oudh ally, in consideration of a payment to the Bengal treasury. The Rohillas were defeated. Some of them fled the country, and so far as possible Hastings obtained terms for those who remained. The fighting, no doubt, on the part of the wazir was conducted with all the savagery of Oriental warfare; but there is no evidence that it was a war of extermination.

Meanwhile the Regulating Act, passed by the North ministry in 1773, changed the constitution of the Bengal government. The council was reduced to four members with a governor-general, with certain indefinite powers of control over the presidencies of Madras and Bombay. Hastings was named in the act as governor-general for a term of five years. The council consisted of General Clavering and Colonel Monson, two third-rate politicians of considerable parliamentary influence; Philip Francis (*q.v.*), then only known as an able permanent official; and Barwell, of the Bengal Civil Service. At the same time a supreme court of judicature was appointed, composed of a chief and three puisne judges, to exercise an indeterminate jurisdiction at Calcutta. The chief-justice was Sir Elijah Impey, already mentioned as a schoolfellow of Hastings at Westminster. The tendency of the Regulating Act was to establish for the first time the influence

of the crown, or rather of parliament, in Indian affairs. The new members of council disembarked at Calcutta on Oct. 19, 1774; and on the following day commenced the long feud which scarcely terminated twenty-one years later with the acquittal of Warren Hastings by the House of Lords. Taking advantage of an ambiguous clause in their commission, the majority of the council (for Barwell uniformly sided with Hastings) reviewed the recent measures of the governor-general. All that he had done they condemned; all that they could they reversed. Hastings was reduced to the position of a cipher at their meetings. They listened to detailed allegations of corruption brought against him by Nuncomar.

Hastings disdained to reply, and referred his accuser to the supreme court. The majority of the council, in their executive capacity, resolved that the governor-general had been guilty of peculation, and ordered him to refund. A few days later Nuncomar was thrown into prison on a charge of forgery preferred by a private prosecutor, tried before the supreme court sitting in bar, found guilty by a jury of Englishmen and sentenced to be hanged. Hastings always maintained that he did not cause the charge to be instituted, and the legality of Nuncomar's trial is thoroughly proved by Sir James Stephen. The majority of the council abandoned their supporter, who was executed in due course. He had forwarded a petition for reprieve to the council, which Clavering took care should not be presented in time, and which was subsequently burnt by the common hangman on the motion of Francis. Meanwhile, Hastings had sent an agent to England with a general authority to place his resignation in the hands of the Company under certain conditions. The resignation was promptly accepted, and one of the directors was appointed to the vacancy. But in the meantime Colonel Monson had died, and Hastings was thus restored, by virtue of his casting vote, to the supreme management of affairs. He refused to ratify his resignation; and when Clavering attempted to seize the governor-generalship, he judiciously obtained an opinion from the judges of the supreme court in his favour. Hastings was never again subjected to gross insult, and his general policy prevailed.

A crisis was now approaching in foreign affairs. Bengal was prosperous, and free from external enemies on every quarter. But the government of Bombay had hurried on a rupture with the Mahratta confederacy at a time when France was on the point of declaring war against England, and when England was faced with revolt in America. Hastings shouldered the whole responsibility of military affairs. The French settlements in India were promptly occupied. On the part of Bombay, the Mahratta war was conducted with procrastination and disgrace. But Hastings avenged the capitulation of Wargaoon by the complete success of his own plan of operations. Goddard with a Bengal army marched across India, and achieved almost without a blow the conquest of Gujarat. Popham stormed the rock fortress of Gwalior, then deemed impregnable and the key of central India; and by this feat held in check Sindhia, the most formidable of the Mahratta chiefs. The Bhonsla Mahratta raja of Nagpur, whose dominions bordered on Bengal, was won over by the diplomacy of an emissary of Hastings.

But while these events were taking place, a new source of embarrassment had arisen at Calcutta. The supreme court assumed a jurisdiction of first instance over the entire province of Bengal. The English common law, was arbitrarily extended to an alien system of society. *Zamindars*, or government renters, were arrested on mesne process; the sanctity of the *zenāna* was violated by the sheriff's officer; the deepest feelings of the people and the entire fabric of revenue administration were alike disregarded. On this point the entire council acted in harmony. Hastings and Francis went joint-bail for imprisoned natives of distinction. At last, after the dispute between the judges and the executive threatened to become a trial of armed force, Hastings set it at rest by a characteristic stroke of policy. A new judicial office was created in the name of the Company, to which Impey was appointed. The understanding between Hastings and Francis was for a short period extended to general policy. Francis received

patronage for his friends, while Hastings was to be unimpeded in the control of foreign affairs. But a difference of interpretation arose. Hastings recorded in an official minute that he had found Francis's private and public conduct to be "void of truth and honour." They met as duellists. Francis fell wounded, and soon afterwards returned to England.

The Mahratta war was not yet terminated, when a more formidable danger threatened the English in India. The Madras authorities had irritated beyond endurance the two greatest Mussulman powers in the peninsula, the nizam of the Deccan and Hyder Ali, the usurper of Mysore, who began to negotiate an alliance with the Mahrattas. A second time the genius of Hastings saved the situation. On the arrival of the news that Hyder had descended from the highlands of Mysore, cut to pieces the only British army in the field, and swept the Carnatic up to the gates of Madras, he adopted a daring policy. He signed a blank treaty of peace with the Mahrattas, who were still in arms, reversed the action of the Madras government towards the nizam, and concentrated all the resources of Bengal against Hyder Ali. Sir Eyre Coote was sent by sea to Madras with all the troops and treasure available; and reinforcements marched southwards under Colonel Pearse along the coast line of Orissa. The landing of Coote preserved Madras from destruction, though the war lasted through many campaigns and only terminated with the death of Hyder. Pearse's detachment was decimated by an epidemic of cholera (perhaps the first mention of this disease by name in Indian history); but the survivors penetrated to Madras, held Bhonsla and the nizam in check, and corroborated the lesson taught by Goddard—that the Company's sepoys could march anywhere, when boldly led.

Hastings had to provide the ways and means for this exhausting war. He reformed the collection of the land tax and the government monopolies of opium and salt were placed upon a remunerative basis. Pressing demands were met by loans, and in at least one case from the private purse of the governor-general. Hastings's fertile mind at once turned to the hoards of the native princes. Chait Sing, raja of Benares, the greatest of the vassal chiefs who had grown rich under British protection, lay under suspicion of disloyalty. The wazir of Oudh had fallen into arrears for the maintenance of the Company's garrison posted in his dominions, and his administration was in disorder. In his case the ancestral hoards were under the control of his mother, the begum of Oudh, into whose hands they had passed when Hastings was powerless in council.

Hastings resolved to make a progress up country to arrange the affairs of both provinces, and bring back all the treasure that could be squeezed out of its holders. When he reached Benares and presented his demands, the raja rose in insurrection, and the governor-general barely escaped with his life. But Popham rallied a force for his defence. The insurgents were defeated again and again; Chait Sing took to flight, and an augmented permanent tribute was imposed upon his successor. The wazir of Oudh consented to everything demanded of him. The begum was charged with having abetted Chait Sing in his rebellion; and after severe pressure applied to herself and her attendant eunuchs, a fine of more than a million sterling was exacted from her. Hastings appears to have been uneasy about the incidents of this expedition, and to have anticipated censure in England. He therefore procured documentary evidence of the rebellious intentions of the raja and the begum, to the validity of which Impey obligingly lent his extra-judicial sanction.

The remainder of Hastings's term of office in India was passed in comparative tranquillity. But in England the long struggle between the Company and the ministers of the crown for the supreme control of Indian affairs and the attendant patronage had reached its climax. The success of Hastings's administration alone postponed the solution. His original term of five years would have expired in 1778; but it was annually prolonged by special act of parliament until his voluntary resignation. Indian affairs formed at this time the hinge on which party politics turned. On one occasion Dundas carried a motion in the House of Commons, censuring Hastings and demanding his recall. The directors of

the Company were disposed to agree; but in the court of proprietors Hastings always possessed a sufficient majority. Fox's India Bill led to the downfall of the Coalition ministry in 1783. The act which Pitt carried in 1784 introduced a new constitution, in which Hastings felt that he had no place. In February 1785 he sailed from Calcutta, after a dignified ceremony of resignation, and amid enthusiastic farewells from all classes.

On his arrival in England, after a second absence of sixteen years, he was well received. Pitt had never taken a side against him, while Thurlow was his pronounced friend. But Francis, whom he had discomfited in the council chamber at Calcutta, was more than his match in the parliamentary arena. Burke had taken the subject races of India under the protection of his eloquence. Francis, who had been the early friend of Burke, supplied him with the animus against Hastings, and with the knowledge of detail, which he might otherwise have lacked. The Whig party followed Burke's lead. Dundas, Pitt's favourite subordinate, had already committed himself by his earlier resolution of censure; and Pitt was induced by motives which are still obscure to incline the ministerial majority to the same side. To meet the oratory of Burke and Sheridan and Fox, Hastings wrote an elaborate minute with which he wearied the ears of the House for two successive nights, and he subsidized a swarm of pamphleteers. The impeachment was decided upon in 1786, but the actual trial did not commence until 1788. For seven long years Hastings was upon his defence on the charge of "high crimes and misdemeanours." During this anxious period he bore himself with characteristic dignity.

At last, in 1795, the House of Lords gave a verdict of not guilty on all charges laid against him; and he left the bar at which he had so frequently appeared, with his reputation clear, but ruined in fortune. The wealth he brought back from India was swallowed up in the expenses of his trial. He forwarded a petition to Pitt praying that he might be reimbursed his costs from the public funds. This petition, of course, was rejected. At last, when he was reduced to actual destitution, it was arranged that the East India Company should grant him an annuity of £4,000 for a term of years, with £90,000 paid down in advance. This annuity expired before his death; and he was compelled to make more than one fresh appeal to the bounty of the Company, which was never withheld. Shortly before his acquittal he had fulfilled the dream of his childhood, by buying back the ancestral manor of Daylesford, where the remainder of his life was passed in honourable retirement. In 1813 he was called on to give evidence upon Indian affairs before the two houses of parliament, which received him with exceptional marks of respect. The university of Oxford conferred on him the honorary degree of D.C.L.; and in the following year he was sworn to the privy council. He died on Aug. 22, 1818, in his 86th year, and lies buried behind the chancel of the parish church, which he had recently restored at his own charges.

In physical appearance, Hastings "looked like a great man, and not like a bad man." The body was wholly subjugated to the mind. A frame naturally slight had been further attenuated by rigorous habits of temperance, and thus rendered proof against the diseases of the tropics. Against his private character not even calumny has breathed a reproach. As brother, as husband and as friend, his affections were as steadfast as they were warm. A classical education and the instincts of family pride saved him from the greed and the vulgar display which marked the typical "nabob." Concerning his second marriage, it suffices to say that the Baroness Imhoff was nearly forty years of age, with a family of grown-up children, when the law of her native land allowed her to become Mrs. Hastings. She survived her husband, who cherished towards her to the last the sentiments of a lover. Her children he adopted as his own; and it was chiefly for her sake that he desired the peerage which was twice held out to him.

Hastings's public career will probably never cease to be a subject of controversy. He was the scapegoat upon whose head parliament laid the accumulated sins, real and imaginary, of the East India Company. If the acquisition of the Indian empire can be supported on ethical grounds, Hastings needs no defence. No

one who reads his private correspondence will admit that even his least defensible acts were dictated by dishonourable motives. On certain of his public measures no difference of opinion can arise. He was the first to attempt to open a trade route with Tibet, and to organize a survey of Bengal and of the eastern seas. He persuaded the *pundits* of Bengal to disclose the treasures of Sanskrit to European scholars. He founded the Madrasa or college for Mahomedan education at Calcutta, primarily out of his own funds; and he projected the foundation of an Indian institute in England. The Bengal Asiatic Society was established under his auspices, though he yielded the post of president to Sir W. Jones.

No Englishman ever understood the native character so well as Hastings; none ever devoted himself more heartily to the promotion of every scheme, great and small, that could advance the prosperity of India. Natives and Anglo-Indians alike venerate his name, the former as their first beneficent administrator, the latter as the most able and most enlightened of their own class. If Clive's sword conquered the Indian empire, it was the brain of Hastings that planned the system of civil administration, and his genius that saved the empire in its darkest hour.

HASTINGS, WILLIAM, BARON (c. 1430-1483), a son of Sir Leonard Hastings (d. 1455), was master of the Mint; and chamberlain of the royal household under Edward IV. Created a baron in 1461, he married Catherine, daughter of Richard Neville, earl of Salisbury. He was faithful to Edward IV. during the king's exile in the winter of 1470-1471. After his return he fought for him at Barnet and at Tewkesbury; he has been accused of taking part in the murder of Henry VI.'s son, prince Edward, after the latter battle. He was made captain of Calais in 1471, and was with Edward IV. when he met Louis XI. of France at Picquigny in 1475, on which occasion he received gifts from Louis and from Charles the Bold of Burgundy. After Edward IV.'s death Hastings refused to ally himself with Richard, duke of Gloucester, afterwards King Richard III. During a meeting of the council on June 13, 1483 he was seized and at once put to death. This dramatic incident is related by Sir Thomas More in his *History of Richard III.*, and has been worked by Shakespeare into his play *Richard III.*

HASTINGS, a municipal, county and parliamentary borough and watering-place of Sussex, England, one of the Cinque Ports, 62 m. S.E. by S. from London, on the S.R. Pop. (1921) 66,495. Rock shelters on Castle hill and numerous flint implements which have been discovered at Hastings suggest an extensive early population, and there are earthworks and a promontory camp probably of early Iron Age or Roman-British date. Hastings was not a Roman settlement, but it was a place of some note in the Anglo-Saxon period. In 795 land at Hastings (Haestingaceaster, Haestingas, Haestingaport) was included in a grant, which may possibly be a forgery, of a South Saxon chieftain to the abbey of St. Denis in France; and a royal mint was established at the town by Aethelstan. The battle of Hastings (*q.v.*) in 1066 was fought near the present Battle Abbey, about 6 m. inland. After the Conquest William I. made the earthworks of the existing castle. By 1086 Hastings was a borough and had given its name to the rape of Sussex in which it lay. The town at that time had a harbour and a market. Whether Hastings was one of the towns afterwards known as the Cinque Ports at the time when they received their first charter from Edward the Confessor is uncertain, but in the reign of William I. it was among them. These combined towns, of which Hastings was the head, had special liberties and separate jurisdiction under a warden. The only charter peculiar to Hastings

was granted in 1589 by Elizabeth, and incorporated the borough under the name of "mayor, jurats and commonalty," instead of the former title of "bailiff, jurats and commonalty." Hastings returned two members to parliament probably from 1322, and certainly from 1366, until 1385, when the number was reduced to one.

It is situated at the mouth of two narrow valleys, and, being sheltered by hills on the north and east, has an especially mild climate. A parade fronts the English Channel, and connects the town on the west with St. Leonard's, the residential quarter which is included within the borough. Both Hastings and St. Leonard's have fine piers; there is a covered parade known as the Marina, and the Alexandra Park of 75 ac. was opened in 1891. There are also numerous public gardens. The sandy beach is extensive, and affords excellent bathing. On the brink of the West Cliff stand a square and a circular tower and fragments of the castle, erected soon after the time of William the Conqueror; together with the ruins, excavated in 1824, of the castle chapel, a transitional Norman structure 110 ft. long, with a nave, chancel and aisles. Besides the chapel there was formerly a college, both being under the control of a dean and secular canons. The deanery was held by Thomas à Becket, and one of the canonries by William of Wykeham. Titus Oates, whose father was rector of the parish, was baptized in 1619 in the Church of All Saints. The prosperity of the town depends almost wholly on its reputation as a watering-place, but there is a small fishing industry. The fish-market is beneath the castle cliff. The parliamentary borough returns one member. The county borough was created in 1888.

Battle of Hastings.—On Sept. 28, 1066, William of Normandy, bent on asserting by arms his right to the English crown, landed at Pevensey. King Harold, who had destroyed the invaders of northern England at the battle of Stamford Bridge in Yorkshire, on hearing the news hurried southward, gathering what forces he could on the way. He took up his position, athwart the road from Hastings to London, on a hill some 6m. inland from Hastings, with his back to the great forest of Anderida (the Weald) and in front of him a long glacis-like slope, at the bottom of which began the opposing slope of Telham Hill. The English

FROM SIR CHARLES Oman, "THE ART OF WAR IN THE MIDDLE AGES" (METHUEN & CO.)

The English, under Harold, held a strong position on a hill and, but for the error of twice pursuing the Normans into the plain, might well have had the best of the battle. All day Harold's infantry withstood the assaults of the Norman foot and heavy cavalry. Only when Harold was mortally wounded, were the Normans able to pierce the English line, and thus open the way for the completion of the Norman conquest of England.

army was composed almost entirely of infantry. The shire levies, for the most part destitute of body armour and with miscellane-

Freeman called this hill Senlac and introduced the fashion of describing the battle as "the battle of Senlac." J. H. Round, however, proved conclusively that this name, being French (Senlecque), could not have been in use at the time of the Conquest, that the battle-field had in fact no name, pointing out that in William of Malmesbury and in Domesday Book the battle is called "of Hastings" (*Bellum Hastingsense*), while only one writer, Ordericus Vitalis, describes it 200 years after the event as *Bellum Senlacium*. See Round, *Feudal England*, p. 333 *et seq.* (1895).

ous and even improvised weapons, were arranged on either flank of Harold's guards (*huscarles*), picked men armed principally with the Danish axe and shield.

Before this position Duke William appeared on the morning of Oct. 14. His host, composed not only of his Norman vassals but of barons, knights and adventurers from all quarters, was arranged in a centre and two wings, each corps having its archers and arblasters in the front line, the rest of the infantry in the second, and the heavy armoured cavalry in the third. Neither the arrows nor the charge of the second line of foot-men, who, unlike the English, wore defensive mail, made any impression on the English standing in a serried mass behind their interlocked shields.¹

Then the heavy cavalry came on, led by the duke and his brother Odo, and encouraged by the example of the minstrel Taillefer, who rode forward, tossing and catching his sword, into the midst of the English line before he was pulled down and killed. All along the front the cavalry came to close quarters with the defenders, but the long powerful Danish axes were as formidable as the halbert and the bill proved to be in battles of later centuries, and they lopped off the arms of the assailants and cut down their horses. The fire of the attack died out and the left wing (Bretons) fled in rout. But as the *fjrd* levies broke out of the line and pursued the Bretons down the hill in a wild, formless mob, William's cavalry swung round and destroyed them, and this suggested to the duke to repeat deliberately what the Bretons had done from fear. Another advance, followed by a feigned retreat, drew down a second large body of the English from the crest, and these in turn, once in the open, were ridden over and slaughtered by the men-at-arms. Lastly, these two disasters having weakened the defenders both materially and morally, William subjected the *huscarles*, who had stood fast when the *fjrd* broke its ranks, to a constant rain of arrows, varied from time to time by cavalry charges. These magnificent soldiers endured the trial for many hours, from noon till close on nightfall; but at last, when the Norman archers raised their bows so as to pitch the arrows at a steep angle of descent in the midst of the *huscarles*, the strain became too great. While some rushed forward alone or in twos and threes to die in the midst of the enemy, the remainder stood fast, too closely crowded almost for the wounded to drop. At last Harold received a mortal wound, the English began to waver, and the knights forced their way in. Only a remnant of the defenders made its way back to the forest; and William, after resting for a night on the hardly-won ground, began the work of the Norman Conquest. Tactically, the battle was a victory for the skilful combination of horseman and archer, its effect increased by ruse, over the infantryman.

HASTINGS, a city of south-western Michigan, U.S.A., on the Chicago, Kalamazoo and Saginaw and the Michigan Central railways; the county seat of Barry county, which has over 200 lakes. The population was 5,132 in 1920 (94% native white) and was estimated locally at 6,000 in 1928. It is in the heart of the pleasure-resort section; shipping point for wheat, corn, live stock and dairy products; and has a large milk condensery, machine shops and factories making tables, car-seals, book-cases and cabinets, automatic fire extinguishers and automobile accessories. The city was founded about 1835 and incorporated in 1871.

HASTINGS, a city of Minnesota, U.S.A., 20m. S.E. of Saint Paul, on the Mississippi river; the county seat of Dakota county. It is served by the Burlington and the Chicago, Milwaukee, St. Paul and Pacific railways. The population was 4,571 in 1920, and was estimated locally at 5,500 in 1928. A State hospital for the

¹There was long a difference of opinion as to whether the English were, or were not, defended by any other rampart than that of the customary "shield-wall." Freeman, apparently as a result of a misunderstanding of a passage in Henry of Huntingdon and the slightly ambiguous verse of Wace in the *Roman du Rou* (ll. 6,991-6,994 and ll. 7,815-7,826), affirms that Harold turned "the battle as far as possible into the likeness of a siege," by building round his troops a "palisade" of solid timber (*Norman Conquest*, iii. 444). This was proved to be a fable by J. H. Round, who sums up the controversy in his *Feudal England*, p. 340 *et seq.*, where references to other monographs on the subject will be found. See also Oman, *History of the Art of War in the Middle Ages*, i, p. 154-155 (1924).

insane is situated here. The city was founded about 1820 and incorporated in 1857.

HASTINGS, a city of Nebraska, U.S.A., 75m. W. by S. of Lincoln, on Federal highway 38; the county seat of Adams county, and an important railroad centre, served by the Burlington, the Chicago and North Western, the Missouri Pacific, the St. Joseph and Grand Island and the Union Pacific railways. The population was 11,647 in 1920 (87% native white). Hastings is the seat of Hastings college (Presbyterian), opened in 1882, and of a State hospital for the insane. It is an important shipping point for grain and live stock, and has a large jobbing and wholesale trade. There are two large cold-storage plants. The manufactures (including brick, brooms, harness and automobile pumps) were valued in 1925 at \$4,421,417. The city was settled in 1872 and incorporated in 1874. The population reached 13,584 in 1890; fell to 7,188 in 1900, following Nebraska's period of hard times; and increased 62% between 1900 and 1920.

HASTINGS-ON-HUDSON, a village of Westchester county, New York, U.S.A., 17 m. above New York city, on the E. bank of the river, and served by the New York Central railroad. The population was 6,311 in 1925. It is the site of the cottage plant of the Orphan Asylum society in New York city (inc. 1807). Chemical, brass and pavement works are the chief industries. The village was incorporated in 1879.

HAT: see HAT MANUFACTURE; HEAD-DRESS.

HATCH, EDWIN (1835-1889), English theologian, was born at Derby on Sept. 14, 1835, and had a distinguished academic career in Canada and Great Britain. His treatises *On the Organization of the Early Christian Churches* (1881, his Brampton lectures), and on *The Influence of Greek Ideas and Usages on the Christian Church* (the Hibbert lectures for 1888) provoked criticism on account of the challenge they threw down to the high-church party, but the research and fairness displayed were admitted on all hands. He died on Nov. 10, 1889.

See W. Sanday in *The Expositor* (February, 1890).

HATCHET, a small, light form of axe with a short handle (see TOOL); for the war-hatchet of the North American Indians and the symbolical ceremonies connected with it see TOMAHAWK.

HATCHETTITE, sometimes termed *Mountain Tallow*, *Mineral Adipocire*, or *Adipocerite*, a mineral hydrocarbon occurring in the coal-measures of Belgium and elsewhere, occupying in some cases the interior of hollow concretions of iron-ore, but more generally the cavities of fossil shells or crevices in the rocks. It is of yellow colour and translucent, but darkens and becomes opaque on exposure. It has no odour, is greasy to the touch, and has a slightly glistening lustre. Its hardness is that of soft wax. The melting point is 46° to 47° C., and the composition is C. 85.55, H. 14.45.

HATCHMENT or **ACHIEVEMENT**, in heraldry, the setting out of armorial bearings, with all that belongs to them, shield,

helm and crest, supporters and motto or word. The term "hatchment" is now usually applied to armorial bearings enclosed in a black lozenge-shaped frame suspended against the wall of a deceased person's house. It remains for from six to twelve months, when it is removed to the parish church. This custom is falling into disuse, though a hatchment was shown in a London street in 1928. It is usual to hang the hatchment of a head of a house at the universities of Oxford and Cambridge over the entrance to his lodge or residence.

If for a bachelor the hatchment has a black ground. If for a single woman, her arms are represented upon a lozenge, bordered with knotted ribbons, also on a black ground. If the hatchment be for a married man, his arms upon a shield impale those of his surviving wife; or if she be an heiress they are placed upon a scutcheon or pretence, and crest and other appendages are added. The dexter half of the ground is black, the sinister white. For a wife whose husband is alive the same arrangement is used,

FROM THE ENCYCLOPEDIA HERALDICA

HATCHMENT OF DECEASED MAN, WIFE SURVIVING

The man's arms, on black background, impinge on his widow's, white background

but the sinister ground only is black. For a widower the same is used as for a married man, but the whole ground is black; for a widow the husband's arms are given with her own, but upon a lozenge, with ribbons, without crest or appendages, and the whole ground is black. When there have been two wives or two husbands the ground is divided into three parts per pale, and the division behind the arms of the survivor is white. Colours and military or naval emblems are sometimes placed behind the arms of military or naval officers. It is thus easy to discern from the hatchment the sex, condition and quality, and possibly the name of the deceased. In Scottish hatchments it is not unusual to place the arms of the father and mother of the deceased in the two lateral angles of the lozenge, and sometimes the 4, 8 or 16 genealogical escutcheons are ranged along the margin.

HATFIELD, town in Hertfordshire, England, 17½ m. N. of London by the L.N.E. railway. Pop. (1921) 5,695. The church of St. Etheldreda contains an Early English round arch with the dog-tooth moulding, but the rest is Decorated and Perpendicular. The Salisbury chapel, north of the chancel, built by Robert Cecil, first earl of Salisbury, is of classic and Gothic styles. In the vicinity is Hatfield House, close to the site of a palace of the bishops of Ely erected in the 12th century. From this palace comes the proper form of the name of the town, Bishop's Hatfield. In 1538 the manor was resigned to Henry VIII. by Bishop Thomas Goodrich of Ely, in exchange for certain lands in Cambridge, Essex and Norfolk; and after that monarch the palace was successively the residence of Edward VI., Queen Elizabeth, during the reign of her sister Mary, and of James I., who exchanged it in 1607 for Theobalds, near Cheshunt, an estate of Robert Cecil, earl of Salisbury, in whose family Hatfield House has since remained. The west wing built in 1608-11 was destroyed by fire in 1835 when the dowager marchioness of Salisbury, widow of the 1st marquess, was burnt. Hatfield House was built, and has been restored and maintained, in the richest style of its period. Some 15th century buildings are now used as offices. The park is 10 m. in circumference. Beyond the river Lea is an example of a monks' walled vineyard.

HATHERLEY, WILLIAM PAGE WOOD, 1ST BARON, cr. 1868 (1801-1881), lord chancellor of Great Britain, son of Sir Matthew Wood, a London alderman and lord mayor who became famous for befriending Queen Caroline and braving George IV., was born in London on Nov. 29, 1801. He was educated at Winchester, Geneva university, and at Trinity college, Cambridge, of which he became a fellow in 1824. He entered Lincoln's Inn, and was called to the bar in 1824. He practised as an equity draughtsman and before parliamentary committees. In 1845 he became Q.C., and in 1847 became M.P. for the city of Oxford. In 1849 he was appointed vice-chancellor of the county palatine of Lancaster, and was solicitor-general in 1851-52. When the Liberal party returned to power in 1853, he was raised to the bench as a vice-chancellor. In 1868 he was made a lord justice of appeal, but before the end of the year was selected by Mr. Gladstone to be lord chancellor. He retired in 1872, but sat occasionally as a law lord. He died in London on July 10, 1881.

HATHRAS, a town of British India, in the Aligarh district of the United Provinces, 29 m. N. of Agra. Pop. (1921), 38,763. At the end of the 18th century it was held by a Jat chieftain, whose ruined fort still stands at the east end of the town, and was annexed by the British in 1803. Hathras has rapidly risen to commercial importance, and now ranks second to Cawnpore among the trading centres of the Doab.

HAT MANUFACTURE. The hat, a covering for the head worn by both sexes, is distinguished from the cap or bonnet by the possession of a brim. The history of the hat as part of the apparel of both sexes, with the various changes in shape which it has undergone, is treated in the article HEAD-DRESS.

At the present day the hat trade is divided into four sections. The first is concerned with the manufacture of hats made from fur; the second, with those made from wool. The productions from these two sections are known as fur felt hats and wool felt hats respectively. The third section engages itself in the manufacture of hats made from materials plaited or woven from straw

or vegetable products of a fibrous nature such as palm leaf, hemp, bamboo, rush, etc. This section is known as the straw hat section of the industry (see STRAW AND STRAW MANUFACTURES). The fourth has to do with hats made from silk plush and is termed silk hatting.

Fur Felt Hats.—The manufacture of fur felt hats under modern conditions entails a series of processes in which highly skilled labour must be employed. The furs used in the industry are coney (rabbit), hare, muskrat, nutria and beaver. The three latter are aquatic and before they can be utilised, have to be washed thoroughly in a strong solution of whale oil soap and water to remove the scum and dirt with which the fur fibres are encrusted. Hare and coney do not require this preliminary washing. All long coarse guard hairs are plucked from the skin, leaving only the smooth soft fur.

After plucking, the remaining fur is treated with a solution of nitrate of mercury, process known as *carrotting*, its object being to open out the minute branches or *barbs* with which each fur fibre is covered. Carrotted skins are fed into a machine which cuts the hide into short shreds, the fur fibre emerges on an endless belt, the hide, now denuded of fur and useless for hat manufacturing purposes being discarded. Fur fibre having been sorted according to its quality value, now undergoes an operation known as *blowing* by which the fibres are fed into a machine whose mechanism contains numerous revolving cylinders bearing thousands of steel teeth or pickers. The action of this machine separates from the individual fur fibres the *kemp* or colouring matter useless for hat manufacturing purposes, and the *down* of the fibre the portion from which fur felt hats are made.

The accumulation of millions of fur fibres into a *hood* from which a finished hat is made is known as *forming*; this, as having reference to the manufacture of fur felt hats, is the process by which fur fibres are knit closely together to form a fabric which shall have the requisite configuration, thickness, homogeneity and stability. For this purpose, a quantity of fur, varying according to the weight and dimensions of hood that is to be made, is fed into a machine and projected into a chamber containing a minutely perforated copper cone. This cone revolves, and to its damp outer side are drawn by suction the myriads of mist-like fur particles; thus the cone rapidly becomes covered with a film of fur. The cone, with its coating of fur, is wrapped round with flannel and, protected further with a metal cover, is immersed in hot water after which the formed hood is removed from the cone.

Each fur fibre has a number of minute branches or barbs and when a mass of such fibres is subjected to heat, moisture and motion with the addition of pressure, the fibres become firmly interlocked. Repetitions of this treatment result in fur felt the shape of which is relatively much the same as that of the original mass, but decreased in size through the working together of fibres and the consequent shrinkage. It is usual to form the hat body or "hood" (the unit which, after many processes, finally emerges as a completed hat) as a cone about 29 in. in height and about 20 in. in diameter. As the hood is handled, not as a cone but in the flat, the diameter of the cone is not considered in the terminology. Thus, the size of the hood above mentioned would be referred to as 29×31, the latter figure being the width of the flat hood across the corners at the base.

After a hood has been formed, the fabric has little cohesion and has to be hardened or shrunk, the object being to interlock or knit together the individual hair fibres so closely that they become inseparable. In the hardening operation, the formed hoods, saturated with water, are stacked together in lots of six to ten, rolled up in a wet cloth and manipulated by hand. Some shrinkage occurs. During this process, the operator must be careful not to tear the hood or treat the delicate fabric so roughly as to cause a "shove" or other damage.

The universal method is to divide the hardening process into four successive shrinking operations known as (a) *hardening*, (b) *starting*, (c) *planking*, (d) *second or final planking*.

These operations are not closely defined, and the extent to which each is carried varies with different manufacturers and with special requirements. To indicate the progressive steps, a hood

29 in. x 31 in. (height 29 in., width across base 31 in.) after hardening will be considered as an example and the following table will show the approximate relative dimensions:

Operation	Dimensions inches
A. After hardening	29 x 31
B. " starting	18 x 24
C. " planking	11 x 16 $\frac{1}{2}$
D. " second planking	10 $\frac{1}{2}$ x 15 $\frac{1}{4}$

Briefly the following is a description of operations B., C. and D.

Starting is a shrinking operation employing an open kettle of boiling water and a machine with three deeply corrugated revolving rollers. The operator takes four to six hoods, wets them in boiling water, piles them one on the other, rolls them up, wraps a canvas cloth round them and tosses the bundle between the rollers of the machine. After a time, the bundle is taken out, unwrapped, unrolled and the hats immersed in boiling water. Each hood is then subjected to hand manipulation. The same hoods are then stacked up again, this time however, their relative positions are changed. They are rolled up again but the rolling is started from another corner or side, the canvas is wrapped on and the bundle tossed between the rollers. These operations are repeated until the operator finds that the shrinking has been carried far enough.

Planking is an operation similar to "starting" employing a three-roller machine over an open hot water bath. The pressure used is somewhat greater, more manipulation is performed and the hoods are put through the machine a greater number of times.

Second planking is another shrinking operation employing similar equipment but requiring still greater pressure and increased manipulation.

The operations by which fur fibre is converted into a fur felt hood comprise what is known as the wet side of hat manufacturing; the processes by which the hood is converted into a finished hat being termed the dry side of the industry. In this regard no general methods are adopted, so much depending on the particular shape or style of headwear it is purposed to produce. Usually, before a hood is converted into a hat, a certain amount of stiffening or proofing is applied. In this operation the hood is treated with a solution composed of shellac and methylated spirit. The hood after this application is placed in a hot oven or kiln the spirit in the solution tending to slightly open the "pores" of the fabric, the heat, whilst evaporating the spirit, driving the shellac into the opened "pores" and there solidifying. The object of this process is to weld the fur fibres so closely together that they cannot be separated during subsequent operations.

The operation of *blocking* or *shaping* is that whereby the hood is converted into its ultimate shape. As a rule, the hood is saturated with dry steam and whilst in this condition pulled over a wooden block the shape of the hat to be produced. The dry steam softens the shellac or "proofing" in the hood allowing the whole to become malleable. The wooden block with its felt covering is now allowed to dry and in drying the shellac again hardens, thus once more tightening up the fur fibres so that the whole fabric has moulded itself to the configuration of the block on which it has been placed. When quite dry, the hood, now converted into a definite shape, is removed from the block and can be regarded as a hat, the trimming of which is merely a matter of fashion requirements.

Wool Felt Hats.—In the manufacture of these articles the wool used is technically known as *noils*, being the short fibre separated by *stapling* from the *tops* or longer wool fibres used in the weaving of cloth. The *noil* is carded through a machine carrying a number of cylinders clothed with wire card. This has a cleaning and strengthening effect and the wool *noil* emerges in a continuous web rather like a lace curtain. This web is wrapped round a double cone which is cut through the middle giving two half cones of carded wool known technically as *formes*.

A *forme* varies in size and in weight according to the type of hat for which it is intended, but before it can be made into a hat it has to be reduced to a *hood*, as in fur felt hat production.

This process known as hardening is conducted by means of steam and rotary rubbing, the action serving to shrink and consolidate the wool, the final hardening being obtained by means of machine rolling whilst the formes are immersed in boiling water. The forme, having been reduced to a hood, is thoroughly dried.

In the shrinking processes, various surface inequalities become apparent on the hood and in order to remove the same and get a perfectly even face to the fabric and to obtain a degree of lustre the hoods are passed through a machine containing a wheel or bob coated with fine sand paper and revolving at a high speed. This is termed pouncing or buffing.

Wool felt hat production from the hood stage proceeds very closely on the lines adopted in the manufacture of fur felt hats.

The operation of dyeing both fur and wool hats is conducted whilst they are in the hood stage and prior to their being stiffened or proofed.

The continent of Europe supplies approximately 90% of the world's fur and wool hoods for hat manufacturing.

Silk Hats.—The silk hat was invented in Florence about 1760, but it was not until the beginning of the 19th century that it was worn to any extent.

A silk hat consists of a light stiff body covered with a plush of silk, the manufacture of which in a brilliant glossy condition is the most important element in the industry. Originally the bodies were made of felt and various other materials, but now calico is chiefly used. The calico is first stiffened with a varnish of shellac, and then cut into pieces sufficient for crown, side and brim. The side-piece is wound round a wooden hat block, its edges are joined by hot ironing, and the crown-piece is put on and similarly attached to the side. The brim, consisting of three thicknesses of calico cemented together, is now slipped over and brought to its position, and thereafter a second side-piece and another crown are cemented on. The whole of the body, thus prepared, now receives a coat of size; subsequently it is varnished, and thus made ready for the operation of covering. In covering this body, the under brim, generally of merino, is first attached, then the upper brim, and lastly the crown and side sewn together are drawn over. All these by hot ironing and stretching are drawn smooth and tight, and as the varnish of the body softens with the heat, body and cover adhere all over to each other without wrinkle or pucker. Dressing and polishing by means of damping, brushing and ironing come next, after which the hat is "velured" in a revolving machine by the application of haircloth and velvet velures, which cleans the nap and gives it a smooth and glossy surface. The brim has only then to be bound, the linings inserted, and the brim finally curled, when the hat is ready for use.

HATSHEPSET or **HATASU** (fl. 1500 B.C.), Egyptian queen, daughter of Thotmes I., sister and queen of the short-reigned Thotmes II., after whose death she secured the crown in spite of opposition from the future Thotmes III., who was the son either of Thotmes I. or of Thotmes II. She acquired fame by her magnificent terrace-temple at Dér el-Bahrî and by her obelisks at Thebes, the expenses of which were partly met by the treasure-hunting expeditions which she sent to South Arabia. The long military inactivity of her reign, during which State affairs were in the hands of her partisans, shook Egyptian power in Asia. In 1841 her tomb was discovered on a cliff behind the Valley of the King's Tomb. Her successor Thotmes III. had her name and figure cut off from the sculptures in her temple and treated the remains of her partisans in a similar manner.

See *Camb. Anc. Hist.* (vol. ii. 1924).

HATTIESBURG, a city of south-eastern Mississippi, U.S.A., on the Leaf river; the county seat of Forrest county. It is on Federal highways 11 and 49, and is served by the Bonhomie and Hattiesburg Southern, the Illinois Central, the Mississippi Central and the Southern railways. The population was 13,270 in 1920 (37% negroes) and was estimated locally at over 20,000 in 1928. It is in the heart of the long-leaf pine belt, which, although the timber is fast vanishing, still supplies many saw-mills. A large plant of the Hercules Powder company makes turpentine, resin and other articles from the pine stumps, and there are railroad shops and sundry smaller manufacturing industries. The factory

output in 1925 was valued at \$6,826,847. Hattiesburg is the seat of the State Teachers college (established 1910) and of the Mississippi Woman's college. During the World War an army cantonment (Camp Shelby) was situated here. The city was founded about 1882, as a lumber centre, and was named after the wife of a railway official who was influential in its establishment. It was incorporated as a town in 1884 and as a city in 1899. In 1908, when Forrest county was erected from part of Perry, it became the county seat. It has a commission form of government.

HATTINGEN, a town in the Prussian province of Westphalia, on the river Ruhr, 21 m. N.E. of Düsseldorf. Pop. (1925) 14,285. Hattingen, which received communal rights in 1396, was one of the Hanse towns. The manufactures include tobacco, and iron and steel goods.

HATTO I. (850?-913), archbishop of Mainz, belonged to a Swabian family, and was probably educated at the monastery of Reichenau, of which he became abbot in 888. The German king, Arnulf, appointed him archbishop of Mainz in 891. He presided over the synod of Tribur in 895, accompanied the king to Italy in 894 and 895, and in 899, when Arnulf died, became regent of Germany, and guardian of the young king, Louis the Child. He compelled Zwentibold, king of Lorraine, an illegitimate son of Arnulf, to recognize Louis. In 896 he secured for himself the abbey of Ellwangen and in 898 that of Lorsch. He assisted the Franconian family of the Conradines in its feud with the Babenbergs, and was accused of betraying Adalbert, count of Babenberg, to death. He retained his influence during the whole of the reign of Louis; and on the king's death in 911 helped to secure the election of Conrad, duke of Franconia, to the vacant throne. When trouble arose between Conrad and Henry, duke of Saxony, afterwards King Henry the Fowler, the attitude of Conrad was ascribed by the Saxons to the influence of Hatto, who wished to prevent Henry from securing authority in Thuringia, where the see of Mainz had extensive possessions. He was accused of complicity in a plot to murder Duke Henry, who in return ravaged the archiepiscopal lands in Saxony and Thuringia. He died on May 15, 913. Stories of cruelty and treachery gathered round his name.

See E. Dümmler, *Geschichte des ostfränkischen Reichs* (Leipzig, 1887-88); G. Phillips, *Die grosse Synode von Tribur* (Vienna, 1865); J. Heidemann, *Hatto I., Erzbischof von Mainz* (1865); G. Waitz, *Jahrbücher der deutschen Geschichte unter Heinrich I.* (Berlin and Leipzig, 1863); and J. F. Bömer, *Regesta archiepiscoporum Maguntinensium*, ed. C. Will (Innsbruck, 1877-86).

HATTON, SIR CHRISTOPHER (1540-1591), lord chancellor of England and favourite of Queen Elizabeth, was a son of William Hatton (d. 1546) of Holdenby, Northants, and was educated at St. Mary Hall, Oxford. A handsome and accomplished man and a good dancer, he attracted the notice of Queen Elizabeth, became one of her gentlemen pensioners in 1564, and captain of her bodyguard in 1572. He received numerous estates and many positions of trust and profit from the queen, and rumour, probably untrue, asserted that he was Elizabeth's lover. Hatton had been made vice-chamberlain of the royal household and a member of the privy council in 1578, and had been a member of parliament since 1571. In 1578 he was knighted, and was now regarded as the queen's spokesman in the House of Commons, being an active agent in the prosecutions of John Stubbs and William Parry. He was one of the negotiators for a marriage between Elizabeth and Francis, duke of Alençon, in 1581; was a member of the court which tried Anthony Babington in 1586; and was one of the commissioners who found Mary queen of Scots guilty. He advised William Davison (*q.v.*) to forward the warrant for her execution to Fotheringay. In the same year (1587) Hatton was made lord chancellor, although he had no great knowledge of the law. He died in London on Nov. 20, 1591, and was buried in St. Paul's cathedral. Elizabeth showed her affection for her favourite in an extravagant and ostentatious manner. She called him her *mouton*, and forced the bishop of Ely to give him the freehold of Ely Place, Holborn, and his name is perpetuated in Hatton Garden. Hatton was a patron of learning, and among his friends was Edmund Spenser. He wrote the fourth act of a tragedy, *Tancred and Gismund*, and his death occasioned several panegyrics in both prose and verse.

See Sir N. H. Nicolas, *Life and Times of Sir Christopher Hatton* (1847); and *Correspondence of the Family of Hatton, being chiefly Letters addressed to Christopher, first Viscount Hatton, 1601-1704*, edited with introduction by E. M. Thompson (1878).

HATTON, JOHN LIP TROT (1809-1886), English musical composer, was born at Liverpool on Oct. 12, 1809. He was virtually a self-taught musician, and found his way to London as a member of Macready's company at Drury Lane in 1832. Ten years after this he was appointed conductor at the same theatre for a series of English operas, and in 1843 his own first operetta, *Queen of the Thames*, was given with success. He had a successful career in Austria and the United States, and from about 1853 was engaged at the Princess's theatre to provide and conduct the music for Charles Kean's Shakespearean revivals. Hatton excelled in the lyrical forms of music, and won popularity by such songs as "To Anthea," "Good-bye, Sweetheart," and "Simon the Cellarer," the first of which may be called a classic in its own way. He died at Margate on Sept. 20, 1886.

HATZFELDT, FRANZ LUDWIG, PRINCE VON (1756-1827), born at Vienna on Nov. 22, 1756 entered the Prussian army in 1795, and in 1806 was made governor of Berlin. Although he showed great moderation when Napoleon entered that city, and had forbidden the removal of arms from the arsenal and the destruction of bridges, the Emperor threatened to bring him before a court-martial and to have him shot as a spy. Hatzfeldt was saved by the entreaties of the princess von Hatzfeldt. After the final defeat of Napoleon, Hatzfeldt was one of the leaders of reaction in Prussia, and won the approbation of Metternich by the ejection of all liberal elements from the government in 1824. Ambassador at Vienna from 1822, he died there on Feb. 3, 1827.

HATZFELDT, MELCHIOR (1593-1658), COUNT OF GLEICHEN and Imperialist general, was born on Oct. 10, 1593 at Krottorf, Hesse. He served with the Imperialist army in the Thirty Years' War, was defeated by the Swedes, led by Bauer, at Wittstock (1636), and in the following year assisted at the relief of Leipzig. From 1639 to 1643 he led the campaigns in Westphalia and the Rhine lands. In 1644 he raised a new army in Bohemia; but in 1645, owing to his defeat at the battle of Jankau, in which he was made prisoner by Torstensson, he was succeeded in his command by Gallas. He retired in 1646. The war in Poland in 1657 brought him from his retirement. He led an army of 16,000 men to the help of the king of Poland against the Swedes, and captured Cracow. He then advanced against Thorn, but his health failed, and he surrendered the command to Montecucculi. He died on Jan. 9, 1658 at Powitzka, near Traehenberg.

See J. Krebs, *Aus dem Leben des kaiserl. Feldmarschalls Grafen Melchior von Hatzfeldt* (1910).

HAUCH, JOHANNES CARSTEN (1790-1872), Danish poet, was born of Danish parents at Frederikshald, Norway, on May 12, 1790. In 1803 he returned with his father to Denmark and served as a volunteer against the English in 1807 before he entered the University of Copenhagen. He became the friend and associate of Steffens and Oehlenschläger, warmly adopting the romantic views about poetry and philosophy. His early dramatic poems (1816) and a lyrical drama, *Rosaura* (1817) had no success, and Hauch decided to resume his scientific studies. An accident which entailed the amputation of a foot drove him back to literature. Again his plays—on historical subjects—were indifferently received, whereupon he turned to fiction, and produced a series of romantic novels. In 1842 he collected his shorter *Poems*. In 1846 he was appointed professor of the Scandinavian languages in Kiel, but returned to Copenhagen when the war broke out in 1848. His dramatic talent was now at its height, and he produced one admirable tragedy after another. In 1861 he published another collection of *Lyrical Poems and Romances*; and in 1862 the historical epic of *Valdemar Seir*, volumes which contain his best work. From 1851, when he succeeded Oehlenschläger, to his death, he held the honorary post of professor of aesthetics at the University of Copenhagen. He died in Rome on March 4, 1872. Of Hauch's dramas *Marshal Stig* is perhaps the best, and of his novels the patriotic tale of *Vilhelm Zabern* is admired the most.

See G. Brandes, "Carsten Hauch" (1873) in *Danske Digtere* (1877); F. Rönning, J. C. Hauch (1890), and in *Dansk Biografisk-Lexicon*, vol. vii. (1893). Hauch's novels were collected (1873-74) and his dramatic works (3 vols., 2nd ed., 1852-59).

HAUCK, ALBERT (1845-1918), German theologian, was born at Hassertrüdingen, M.-Franken, on Dec. 9, 1845, and studied at the universities of Erlangen and of Berlin. He took orders, and from 1875-8 was pastor at Frankenheim. Hauck was professor of theology at Erlangen (1882-89), and at Leipzig (1889-98), and then for a year rector of the university. He died on April 7, 1918. His most important work is *Kirchengeschichte Deutschlands* (5 vols. 1887-1911; 5th ed. 1920). He edited the 3rd edition of the *Realencyclopädie* of Protestant theology (24 vols. 1896-1913).

HAUER, FRANZ, RITTER VON (1822-1899), Austrian geologist, born in Vienna on Jan. 30, 1822, was son of Joseph von Hauer (1778-1863), who was equally distinguished as a high Austrian official and authority on finance and as a palaeontologist. In 1886 Franz Hauer became superintendent of the imperial natural history museum in Vienna. Among his special geological works are those on the Cephalopoda of the Triassic and Jurassic formations of Alpine regions (1855-1856). His most important general work was that of the *Geological Map of Austro-Hungary*, in twelve sheets (1867-1871; 4th ed., 1884, including Bosnia and Montenegro). He died on March 20, 1899.

PUBLICATIONS.—*Beiträge zur Paläontologie von Österreich* (1858-59); *Die Geologie und ihre Anwendung auf die Kenntnis der Bodenbeschaffenheit der österr.-ungar. Monarchie* (1875; ed. 2, 1878). See *Memoir* by Dr. E. Tietze; *Jahrbuch der K. K. geolog. Reichsanstalt* (1899, reprinted 1900, with portrait).

HAUFF, WILHELM (1802-1827), German poet and novelist, was born at Stuttgart on Nov. 29, 1802, and educated at the Klosterschule at Blaubeuren, and the university of Tübingen. For the children of the Württemberg minister of war, von Hügel, to whom he acted as tutor, he wrote his *Märchen*, which he published in his *Märchenalbum auf das Jahr 1826*. To the same period belong his *Mitteilungen aus den Memoiren des Satan* (1826) and *Der Mann im Monde* (1825). The latter, a parody of the novels of H. Clarendon (pseudonym of K. G. S. Heun) was published under Clarendon's name, and Hauff was mulcted in damages. Nevertheless he went on to write a *Kontroverspredigt über H. Clarendon und den Mann im Monde* (1826). His historical romance *Lichtenstein* (1826), treating of the reign of duke Ulrich of Swabia, was one of the early imitations of Walter Scott. His other works include the charming *Bettlerin vom Pont des Arts*; *Phantasien im Bremer Ratskeller* (1827); and some short poems which have passed into *Volkslieder*, among them *Morgenrot*, *Morgenrot, leuchtest mir zum frühen Tod*; and *Steh' ich in finst'rer Mitternacht*. Hauff died prematurely on Nov. 18, 1827. The freshness and originality of Hauff's talent, his inventiveness and his genial humour have made him a minor classic.

See his *Sämtliche Werke*, ed. G. Schwab (3 vols., 1830-34; 5 vols., 18th ed., 1882); ed. F. Bobertag (1891-97); and a selection by M. Mendheim (3 vols., 1891). These and later editions contain biographical material.

HAUG, MARTIN (1827-1876), German orientalist, was born at Ostdorf near Balingen, Württemberg, on Jan. 30, 1827. He studied oriental languages, especially Sanskrit, at Tübingen and Göttingen, and in 1854 settled as *Privatdozent* at Bonn. In 1856 he removed to Heidelberg, where he assisted Bunsen in his literary work; and in 1859 he went out to India, where he became superintendent of Sanskrit studies and professor of Sanskrit in Poona. The result of his researches into Zend literature was a volume of *Essays on the sacred language, writings and religion of the Parsees* (Bombay, 1862). Having returned to Stuttgart in 1866, he was called to Munich as professor of Sanskrit and comparative philology in 1868. He died on June 3, 1876.

HAUGE, HANS NIELSEN (1771-1824), Norwegian preacher, was born in the parish of Thunö, Norway, on April 3, 1771, the son of a peasant. In his twenty-sixth year, believing himself to be divinely commissioned, he began to preach, calling people to repentance and attacking rationalism. In 1804 he was arrested, and only released from prison in 1814. He died at

Breddwill, near Christiania, on March 29, 1824. His pietistic adherents, who did not formally break with the church, but placed great stress on the evangelical doctrines of faith and grace, were called *Haugianer* or *Leser* (i.e., Readers).

See C. Bang, *Hans Nielsen Hauge og hans Samtid* (Christiania; 2nd ed., 1875); O. Rost, *Nogle Bemaerkninger om Hans Nielsen Hauge og hans Reining* (1883).

HAUGESUND, a seaport of Norway in Stavanger amt (county), on the west coast, 34m. N. by W. of Stavanger. Pop. (1927) 17,117. It is an important fishing centre, particularly for herrings which form the chief export. Mackerel and lobsters are also important. The principal imports are coal and salt. There are factories for woollen goods and margarine, and a small shipbuilding industry. The town is difficult of access by land. Haugesund is the reputed death-place of Harald Haarfager, to whom an obelisk of red granite was erected in 1872 on the thousandth anniversary of his victory at the Hafsford (near Stavanger) whereby he won the sovereignty of Norway. The memorial stands 1½m. N. of the town, on the Haraldshaug.

HAUGHTON, WILLIAM (fl. 1598), English playwright, collaborated in many plays with Henry Chettle, Thomas Dekker, John Day and Richard Hathway. He was working for the Admiral's Company from 1597 to 1602, and Philip Henslowe, on March 10, 1600, lent him ten shillings "to release him out of the Clink." He had a share with Dekker and Chettle in *The Patient Grissill* (1599), and *Englishmen for my Money*, or *A Woman will have her Will* (1598) is ascribed to his sole authorship.

Englishmen for my Money is reprinted in vol. x. of W. C. Hazlitt's edition of Dodsley's *Old Plays*; also by W. W. Greg (1912, Malone Society Reprints), and by A. C. Baugh (1917). A list of lost and doubtful plays in which Haughton had a share is given in E. K. Chambers, *The Elizabethan Stage*, vol. iii. (1923).

HAUGWITZ, CHRISTIAN AUGUST HEINRICH KURT, COUNT VON, FREIHERR VON KRAPPITZ (1752-1832), Prussian statesman, was born on June 11, 1752, at Peucke near Öls. In 1791 he was elected by the Silesian estates general director of the province. At the invitation of Frederick William II. he entered the Prussian service, became ambassador at Vienna in 1792 and a member of the cabinet at Berlin.

Haugwitz, who had attended the young emperor Francis II. at his coronation and been present at the conferences held at Mainz to consider the attitude of the German powers towards the Revolution, was at first opposed to intervention in France, but eventually entered on the negotiations for the subsidy treaty between Great Britain and Prussia, and Great Britain and Holland, signed at The Hague on April 19, 1794. Haugwitz, however, was not the man to direct a strong and aggressive policy; and in October the denunciation by Great Britain of The Hague treaty broke the last tie that bound Prussia to the Coalition. The separate treaty with France, signed at Basle on April 5, 1795, was mainly due to the influence of Haugwitz.

No guarantee of the retention of the Rhine provinces of the Empire had been inserted in the Basle treaty; but Haugwitz and the king hoped to preserve them by establishing the armed neutrality of North Germany and securing its recognition by the French republic. This policy was rendered futile by the victories of Napoleon Bonaparte and the virtual conquest of South Germany by the French. Haugwitz recognized this fact, and in vain urged Frederick William III. to join the new Coalition in 1798. When the king refused his urgent advice to demand the evacuation of Hanover by the French in 1803, he offered to resign, and in Aug. 1804 he was replaced by Hardenberg. In his retirement Haugwitz was still consulted, and used his influence against Hardenberg's policy of a *rapprochement* with France. He was recalled, as Hardenberg's colleague in the foreign office, in 1805. He pursued a vacillating policy, and was definitely worsted by Napoleon. The ultimatum he was to have conveyed to the French emperor was never delivered. Instead he signed the treaties of Schönbrunn (Dec. 15, 1805) and Paris (Feb. 15, 1806), which gave Hanover to Prussia in return for Ansbach, Cleves and Neuchâtel. The Prussian ultimatum to Napoleon was eventually forced upon him, and with the battle of Jena (Oct. 14), his political career came to an end.

The last eleven years of his life were spent in Italy, and he died in Venice on Feb. 9, 1832. During his retirement in Italy he wrote memoirs in justification of his policy, a fragment of which dealing with the episode of the treaty of Schönbrunn was published at Jena in 1837.

See L. von Ranke, *Hardenberg u. d. Gesch. des preuss. Staates* (Leipzig, 1879-81), note on Haugwitz's memoirs in vol. ii.; *Denkwürdigkeiten des Staatskanzlers Fürsten von Hardenberg*, ed. Ranke (5 vols., Leipzig, 1877).

HAUNTINGS. The supposed manifestations of existence by spirits of the dead in houses or places familiar to them in life. See SPIRITUALISM and PSYCHICAL RESEARCH.

HAUPT, MORITZ (1808-1874), German philologist, was born at Zittau, in Lusatia, on July 27, 1808. On the close of his university course at Leipzig (1830) he studied Greek, Latin, German, Old French, Provençal and Bohemian. In Sept. 1837 he "habilitated" at Leipzig as *Privatdozent*, and his first lectures, dealing with such diverse subjects as Catullus and the *Nibelungenlied*, indicated the twofold direction of his labours. He became professor extraordinarius (1841) and then professor ordinarius (1843) of German language and literature. But, having taken part in 1849 with Otto Jahn and Theodor Mommsen in a political agitation for the maintenance of the imperial constitution, Haupt was deprived of his professorship by a decree of April 22, 1851. Two years later, however, he was called to succeed his friend Lachmann at Berlin, and became a member of the Berlin academy. He died on Feb. 5, 1874.

Haupt edited texts of Ovid, Catullus, Tibullus, Propertius, Horace and Virgil. As early as 1836, with Hoffmann von Fallersleben, he started the *Altdeutsche Blätter*, which in 1841 gave place to the *Zeitschrift für deutsches Altertum*, of which he continued editor till his death. Hartmann von Aue's *Erec* (1839) and his *Lieder*, *Büchlein* and *Der arme Heinrich* (1842), Rudolf von Ems's *Guter Gerhard* (1840) and Conrad von Würzburg's *Engelhard* (1844) are the principal German works which he edited. Three volumes of his *Opuscula* were published at Leipzig (1875-77).

See Kirchhoff, "Gedächtnisrede," in *Abhandl. der Königl. Akad. der Wissenschaften zu Berlin* (1875); Otto Belger, *Moritz Haupt als Lehrer* (1879); Sandys, *Hist. Class. Schol.* iii. (1908).

HAUPTMANN, GERHART (1862-), German author, was born in Obersalzbrunn, Silesia, on Nov. 15, 1862, the son of an innkeeper. He was educated locally and in Breslau, and was at first intended for a farmer. His instincts were, however, always artistic. In 1880-81 he spent two years at the Breslau school of art, followed by a year's study at Jena university. He then travelled in France, Spain and Italy and in 1884 established himself in Rome as a sculptor. Obligated by reasons of health to return to Germany, he lived in Dresden, Berlin (where he had thoughts of going on the stage) and Erkner, near Berlin, later settling at Schreiberhau, Silesia.

A man of great versatility and exceptionally wide artistic sympathies, Hauptmann hesitated long before choosing literature as his means of expression. His earliest work was *Promethidenlos* (1885). In 1889 he began the series of dramas which set him at a bound at the head of the German dramatic writers of his time. Hauptmann's first drama, *Vor Sonnenaufgang* (1889), appeared at a moment when the cultivated German public read nothing but Scandinavian, French and Russian authors, and German writers, to gain a hearing, were obliged to adopt foreign pseudonyms. Hauptmann's genius forced German attention back to its native authors. He was at heart always rather a romanticist than a naturalist, but circumstances forced him to begin as a naturalist. *Vor Sonnenaufgang* aroused a storm of criticism similar to that encountered by Ibsen and Strindberg, by whose side he took his place. He persevered, however, with a series of dramas depicting the life of the working classes or the poverty-stricken middle classes until, by 1910, German naturalism was fully established. These naturalist dramas include *Einsame Menschen* (1891), *Fuhrmann Henschel* (1898), *Gabriel Schillings Flucht* (1912), and most notably *Die Weber* (1892), a social drama on the grand scale, representing the rise, outbreak, development and failure of

a miniature revolution, and perhaps Hauptmann's greatest work. These dramas had created the type of German naturalism; but in Hauptmann exact and conscientious observation was mellowed by his great sensibility and feeling for beauty and genuine poetic gift. His romantic tendencies found play as early as 1892 in the somewhat fantastic *Hanneles Himmelfahrt*, while *Die Versunkene Glocke* (1896) and *Und Pippa Tanzt* (1906) are fairy pieces in a rather vague symbolic style. Hauptmann's insight, intellectual honesty and earnest purpose maintained him in the position which he had won as the foremost and most representative German writer. His later plays, however, the best of which was perhaps *Der Weisse Heiland* (1919), met with less appreciation than his earlier work. The subjective vision which now permeated his work perhaps hardly replaced his earlier peculiar gift for reproducing the life of others. Hauptmann's narrative work is less famous than his dramatic, but he has produced two stories almost perfect in form and content: *Der Narr in Christo Emanuel Quint* (1910) and *Der Ketzer von Soana* (1918), as well as one of the most famous of German novels in *Atlantis* (1912). Hauptmann's verse, though dignified and sincere, lacks warmth.

See C. Holl, *Gerhart Hauptmann*, etc. (1913); W. Bonsels, *Das junge Deutschland und der grosse Krieg, aus Anlass des Briefwechsels Romain Rollands mit G. Hauptmann über den Krieg und die Kultur* (1914); A. Esprey, *G. Hauptmann und wir Deutschen* (1916); J. H. Marschan, *Das Mitleid bei G. Hauptmann*, bib. (1919); Paul Fechter, *Gerhart Hauptmann* (1922); P. Schlenker, *G. Hauptmann* (1922).

HAUPTMANN, MORITZ (1792-1868), German musical composer and writer, was born at Dresden, on Oct. 13, 1792, and studied music under Scholz, Lanska, Grosse and Morlacchi, the rival of Weber. Afterwards he completed his education as a violinist and composer under Spohr, and till 1820 held various appointments in private families, varying his musical occupations with mathematical and other studies bearing chiefly on acoustics and kindred subjects. For a time also Hauptmann was employed as an architect, but all other pursuits gave place to music, and a tragic grand opera, *Mathilde*, dates from 1826. In 1822 he entered the orchestra of Cassel, again under Spohr's direction, and taught composition and musical theory to Ferdinand David, Burgmüller, Kiel and others. His compositions at this time chiefly consisted of motets, masses, cantatas and songs. In 1842 Hauptmann became cantor at the Thomas-school of Leipzig where one of his predecessors had been J. S. Bach, and professor at the conservatoire. Here his unique gift as a teacher developed, and was acknowledged by a crowd of enthusiastic pupils, among whom were Joachim, von Bülow, Sullivan and Cowen. He was, as already indicated, a mathematician and a philosopher as well as a musician, and brought his studies in philosophy to bear on music. His most important publication was *Die Natur der Harmonik und Metrik* (1853, Eng. trans. *The Nature of Harmony and Metric*, 1888), a standard work. He died on Jan. 3, 1868.

Amongst his vocal compositions—by far the most important portion of his work—may be mentioned two masses, choral songs for mixed voices (*Op.* 32, 47), and numerous part songs, which remain in the repertory of most German choirs.

See a selection from the two German volumes of his letters to Hauser, Spohr and others, *Letters of a Leipzig Cantor* (1892).

HAURÉAU (JEAN), BARTHELEMY (1812-1896), French historian, was born in Paris. He was a deputy to the National Assembly of 1848; contact with the revolution gradually cooled his old ardour. He became director of the ms. department of the Bibliothèque Nationale but resigned after the *coup d'état* of 1851, and refused to accept any administrative post until after the fall of the empire. He was director of the national printing press from 1870 to 1881, and in 1893 became director of the Fondation Thiers. He died on April 29, 1896.

Hauréau devoted his life to the religious, philosophical and more particularly the literary history of the middle ages. From the time of his appointment to the Bibliothèque Nationale up to the last days of his life he made abstracts of all the mediaeval Latin writings (many anonymous or of doubtful attribution) relating to philosophy, theology, grammar, canon law and poetry, carefully noting on cards the first words of each passage. After his death this index of *incipits*, arranged alphabetically, was pre-

sent to the Académie des Inscriptions, and a copy was placed in the ms. department of the Bibliothèque Nationale.

See notice by Paul Meyer prefixed to vol. xxxiii. of the *Histoire littéraire de la France*.

HAUSA, a long-headed people of northern Nigeria (Emirates of Sokoto, Katsina, Zaria) and, in the French area north of Kano, the sultanate of Zinder. They are of mixed blood; the organization is feudal with local centralization. The paramount chief is assisted by a council of notables and court functionaries. The Muslim laws of inheritance are applied. Marriage between brothers-in-law and sisters-in-law is common. The oldest brother of the deceased succeeds to headship of the family. They are cultivators and great traders, whose harmonious language is spread over the whole of Central Africa. They are Mohammedans, but there are many animistic survivals and traces of totemism, with belief in witchcraft. The priest-king was killed in certain eventualities.

See Tremearne, *Hausa Superstitions and Customs*; Meek, *The Northern Tribes of Nigeria* (1925). (H. LAB.)

LANGUAGE

The Hausa language is, perhaps, the most important of the many languages of West Africa—certainly the most important in Northern Nigeria. It is spoken as their mother tongue by over 3½ million people in the 14 Hausa States (enclosed between the Niger, the Benue and the southern edge of the Sahara), but it extends far beyond these limits. The late Robert Needham Cust expressed the opinion that "it has a great extra-territorial expansion, and from various causes, especially the dispersion of Hausa slaves among other tribes"—to which might have been added, the frequent journeys of Hausa traders back and forth across the Sahara—"it has obtained the rank of a Lingua Franca, and it is the general vehicle of communication between tribes speaking different languages."

Affinities and Structure.—The languages of Africa fall into three distinct families, now, by general agreement, called the Sudanic, Bantu and Hamitic. To the first belong such as Twi, Ewe, Yoruba, the Shilluk of the Upper Nile, the Luo ("Kavirondo") of Kenya Colony, and many others, which have no grammatical inflections, contain chiefly words of one syllable and make great use of *tone*, pitch, or "musical intonation" to distinguish words otherwise alike in sound, but different in meaning, while there is little or no stress accent. The Bantu family (*q.v.*) has a somewhat elaborate grammatical structure; stress accent is very marked, but most of the languages also possess tone. The Hamitic languages, which include Hausa, Berber, Somali, Galla and several others, as well as Ancient Egyptian, are classed as *Inflected* and share with the other two great families (the Indo-European and Semitic) the possession of *grammatical gender*, or the distinction of masculine and feminine indicated by the form of a word, as in our pronouns "he" and "she," or terminations like *-ess* as in "lion-ess." (It is curious that this feature is absent from all known languages outside the three great families mentioned above, sex being indicated, where necessary, by using a different word, as we do, *e.g.*, in the case of "bull" and "cow," or by adding the word for "man" and "woman," saying, for instance, "man-lion" and "woman-lion.") The plural, as a rule, is indicated either by a termination ("suffix") or a change of vowel in the body of the word, comparable to our "man, men," "mouse, mice." More than one plural is used (in Hausa at least two of these are recognized): one to indicate several individuals of a species, another to express multitude (sometimes called a "collective plural") and one enumerating several *kinds* of the same object. There is no article, definite or indefinite, in the Bantu languages (one or two exceptions seem to

MUSLIM HAUSA HEADS-MAN

A mixture of Arab with Negro blood has made this people of the central Sudan intelligent and keen-witted, especially at trading

arise from European influence). Hausa agrees with them in this respect, though some other Hamitic tongues do not. Another point of resemblance is the position of the genitive; both Hamitic and Bantu place the thing possessed before the possessor, whereas the more typical Sudanic languages reverse this arrangement and say, *e.g.*, "the king's horse" (or rather, literally, "king horse," there being no possessive inflection). In Hausa this would be *doki-n sarki* "(the) horse of (the) king" and in Swahili (to take a specimen Bantu language) it would be *farasi* ("horse") *wa* ("of") *mfalme* ("king"). As already implied, Hausa possesses the masculine and feminine genders which (there being no neuter) are applied to things without life as well as to persons. The pronoun "he" is in Hausa *shi*, "she" is *ita*; there are other forms used with different tenses of the verb. Masculine and feminine nouns are distinguished from each other by their terminations, and adjectives have to agree with them.

Phonology.—The *sounds* of Hausa have only in recent years been studied with any approach to accurate analysis, and the last word has not been said on the subject. They should not in themselves prove difficult, provided sufficient attention is paid to such hints as those given by Capt. F. W. Taylor in his *Hausa Grammar*; *e.g.*, "When learning Hausa colloquially it is of the greatest importance to watch a native's mouth. Generally speaking, he has a wide mouth and often articulates with the corners drawn well back and all the front teeth showing. . . . Apparently (the tongue) is larger and less mobile, and appears to be used more *en bloc* and in a more frontal position than is the case with the average Englishman."

A very important point, as regards pronunciation of the Hausa language, is the existence of tones, a feature absent from other Hamitic languages, and indicating the fact that the Hausa people, though Hamitic by language, are not so by race. Their language must have been brought to them by immigrants from the north—perhaps at the time when the Batutsi entered Ruanda and ancestors of the present royal family came into Uganda. (But in these last instances, the immigrants acquired the Bantu language of the country.) Tones are found in many, if not most of the Bantu languages, and are an essential characteristic of the Sudanic, where many words, otherwise similar, can only be distinguished in this way; so essential that the originally Sudanic-speaking Hausa imported it into their acquired tongue. "Hausa," says Capt. Taylor, "occupies a position midway between the tone languages, such as Yoruba, and the stress languages, such as English, for, though the tones of the Hausa nouns are almost constant, the verb undergoes so many changes that it has in many cases discarded a pitch accent and acquired a stress accent."

Literature.—Hausa is written by the natives in the Arabic character (here called Ajami) with certain distinctive peculiarities which prevent its being easily read by anyone familiar with Arabic script only. There exist large numbers of Ajami mss., though only a few have appeared in print. Some poems of a religious character, collected by the late Canon Charles Robinson, were published by the Cambridge University Press in 1902, and the two volumes of Hausa tales edited and translated by Capt. R. Sutherland Rattray contain, both the Hausa text in Roman transliteration, and the original Ajami in facsimile. The language was systematically studied by William Balfour Baikie, the British consul at Lokoja, on the Niger, from 1857 to 1864; by the missionary, James Frederick Schön (died 1889), whose first attempt at a grammar was published in 1843 (he afterwards produced a fuller grammar and a dictionary which is still valuable); and the great traveller, Heinrich Barth (1821-65). Schön wrote down, from the dictation of two native youths, the narrative of their life and travels, and a number of folk-tales, which have been published under the title of *Magana Hausa*. Mention should also be made of Maj. Edgar's *Litafi na tatsuniyoyi na Hausa*—three volumes of Hausa stories. Others have collected proverbs, of which, as in most African languages, there is a great variety, usually shrewd and racy, and of great value, as throwing light on native ways of thought. The requirements of native education have already necessitated the production of several readers

and other school books, and the whole of the Bible has been translated into Hausa.

It may be of interest to give a few proverbs as specimens of the language:

Rashin farin wata, tamrārō kē hashē.

"When the moon is not full, the stars are bright."

Kāwā mai-yāyā ita kē tsōrō shirwa.

"It is the hen with chickens that fears the hawk."

Idan mugun mutun yā shibka zanba, kai ka sa lauƙe ka yankē.

"If a bad man has sown evil, do you set your sickle to it and cut it down."

Alla bā Ka da kēta, gōnar mayē ruē Kakwāyēi.

"Allah, Thou hast no evil, Thou sendest rain (even) on the wizard's garden."

(A. WE.)

HAUSER, KASPAR (c. 1812–1833), a German youth whose origin is surrounded with mystery. The first record of him is in May 1828, when he appeared in Nuremberg, dressed as a peasant, and with a helpless and bewildered air that attracted attention. In his possession was found a letter purporting to be written by a labourer, stating that the boy was given into his custody on Oct. 7, 1812, and that according to agreement he had instructed him in reading, writing and the Christian religion, but had kept him in close confinement. With this letter was enclosed another purporting to be written by the boy's mother, stating that he was born on April 30, 1812, that his name was Kaspar, and that his father, an ex-cavalry officer in the 6th regiment at Nuremberg, was dead. For some time the lad was detained at Nuremberg as a vagrant; Professor Daumer then undertook his guardianship and the charge of his education. Earl Stanhope became interested in his history, and sent him in 1832 to Ansbach to be educated. He became clerk in the office of Feuerbach, president of the court of appeal; and his strange history was almost forgotten when interest in it was revived by his death as the result of a wound received on Dec. 14, 1833. Whether the wound was self-inflicted or whether, as he alleged, it was dealt by a stranger, is unknown. Kaspar Hauser's story has been used by Jakob Wassermann in a novel (1908) and by Kurt Martens in a play (1904).

The theory of Daumer and Feuerbach and other pamphleteers (see E. E. Evans, *Story of Kaspar Hauser from Authentic Records*, 1892) was that the youth was the crown prince of Baden, the legitimate son of the grand-duke Charles of Baden, and that he had been kidnapped at Karlsruhe in Oct. 1812 by emissaries of the countess of Hochberg (morganatic wife of the grand-duke) in order to secure the succession to her offspring; but this theory was answered in 1875 by the publication in the Augsburg *Allgemeine Zeitung* of the official record of the baptism, post-mortem examination and burial of the heir supposed to have been kidnapped. See *Kaspar Hauser und sein badisches Prinzentum* (Heidelberg, 1876). The evidence was analyzed by Andrew Lang in his *Historical Mysteries* (1904), with results unfavourable to the "romantic" version of the story. Lang's view was that possibly Kaspar was a sort of "ambulatory automatist," an instance of a phenomenon, known by other cases to students of psychical abnormalities, of which the characteristics are a mania for straying away and the persistence of delusions as to identity; but he inclines to regard Kaspar as simply a "humbug." The "authentic records" purporting to confirm the kidnapping story Lang stigmatizes as "worthless and impudent rubbish."

See also J. Mayer, *Authentische Mitteilungen über Kaspar Häuser* (1913); and H. Pies, *Kaspar Hauser, Augenzeugenberichte und Selbstzeugnisse* (2 vols., 1925).

HAUSMANN, JOHANN FRIEDRICH LUDWIG (1782–1859), German mineralogist, was born at Hanover on Feb. 22, 1782. He was educated at Göttingen, and in 1811 returned there as professor, holding his chair for over 40 years. Hausmann wrote on gypsum, pyrites, feldspar, tachylite, cordierite and on

some eruptive rocks, and he devoted much attention to the crystals developed during metallurgical processes. He died Dec. 26, 1859.

PUBLICATIONS.—*Grundlinien einer Encyclopädie der Bergwerkswissenschaften* (1811); *Reise durch Skandinavien* (5 vols., 1811–18); *Handbuch der Mineralogie* (3 vols., 1813; 2nd ed., 1828–47).

HAUSRATH, ADOLPH (1837–1909), German Protestant theologian, was born at Karlsruhe on Jan. 13, 1837, and was educated at Jena, Göttingen, Berlin and Heidelberg, where he became *Privatdozent* in 1861, professor extraordinary in 1867 and ordinary professor in 1872. He was a disciple of the Tübingen school. Among other works he wrote *Der Apostel Paulus* (1865), *Neutestamentliche Zeitgeschichte* (1868–73, 4 vols.; Eng. trans.), *D. F. Strauss und die Theologie seiner Zeit* (1876–78, 2 vols.), and lives of *Richard Rothe* (2 vols. 1902), and *Luther* (1904). Under the pseudonym George Taylor he wrote several historical romances, *Antinous* (1880), and others. He died on Aug. 2, 1909.

HAÜSSER, LUDWIG (1818–1867), German historian, was born at Kleeburg, Alsace, became professor of history at Heidelberg, and was a member of the Baden parliament. Häusser was one of the leaders of the party which desired the exclusion of Austria from the German Confederation. He died at Heidelberg on March 19, 1867. Häusser's chief work is *Die deutsche Geschichte vom Tode Friedrichs des Grossen bis zur Gründung des deutschen Bundes* (Leipzig, 1854–57, 4 vols.). See E. Marcks, *Ludwig Häusser* (1903).

HAUSSMANN, GEORGES EUGENE, BARON (1809–1891), French financier, whose name is associated with the rebuilding of Paris, was born in that city on March 27, 1809, of a Protestant family, German in origin. He was educated at the Collège Henri IV., and subsequently studied law, attending simultaneously the classes at the Paris conservatoire of music, for he was a good musician. He became *sous-préfet* of Nérac in 1830, and advanced rapidly in the civil service until in 1853 he was chosen by Persigny prefect of the Seine in succession to Jean Jacques Berger, who hesitated to incur the vast expenses of the imperial schemes for the embellishment of Paris. Haussmann laid out the Bois de Boulogne, and made extensive improvements in the smaller parks. The gardens of the Luxembourg Palace were cut down to allow of the formation of new streets, and the Boulevard de Sebastopol, the southern half of which is now the Boulevard St. Michel, was driven through a populous district. A new water supply, a gigantic system of sewers, new bridges, the opera, and other public buildings, the inclusion of outlying districts—these were among the new prefect's achievements, accomplished by the aid of a bold handling of the public funds which called forth Jules Ferry's indictment, *Les Comptes fantastiques de Haussmann*, in 1867. A loan of 250 million francs was sanctioned for the city of Paris in 1865, and another of 260 million in 1869. These sums represented only part of his financial schemes, which led to his dismissal by the government of Émile Ollivier. After the fall of the Empire he spent about a year abroad, but he re-entered public life in 1877, when he became Bonapartist deputy for Ajaccio. He died in Paris on Jan. 11, 1891. Haussmann had been made senator in 1857, member of the Academy of Fine Arts in 1867, and grand cross of the Legion of Honour in 1862. His name is preserved in the Boulevard Haussmann. His later years were occupied with the preparation of his *Mémoires* (3 vols., 1890–1893). See also PARIS.

HAUSSONVILLE, JOSEPH OTHENIN BERNARD DE CLÉRON, COMTE D' (1809–1884), French politician and historian, was born in Paris on May 27, 1809, the son of Charles Louis Bernard de Cléron, comte d'Haussonville (1770–1846), chamberlain at the court of Napoleon. After holding various diplomatic posts, he was elected to the chamber of deputies in 1842, and became a life-senator in 1878. In the senate he defended the religious associations against the anti-clericals. He died in Paris on May 28, 1884.

His works include: *Histoire de la politique extérieure du gouvernement français de 1830 à 1848* (2 vols. 1850), *Histoire de la réunion de la Lorraine à la France* (4 vols. 1859), *L'Eglise romaine et le premier empire, 1800–14* (5 vols., 1864–79); *La France et la Prusse devant l'Europe* (a pamphlet, 1870). He edited at Brussels *Le Bulletin français*.

His wife Louise (1818-1882), daughter of Duc Victor de Broglie published *Robert Emmett* (1858) and other books.

His son GABRIEL PAUL OTHENIN DE CLÉRON was born at Gurcy-le-Châtel (Seine-et-Marne) on Sept. 21, 1843. In 1891, as representative of the Comte de Paris in France, he tried to strengthen the Orleanist party, but their prospects were dashed in 1894 by the death of the comte de Paris. D'Haussonville died in Paris on Sept. 1, 1924.

His works include: *Etudes biographiques et littéraires* (2 series, 1879 and 1888); *Le Comte de Paris, souvenirs personnels* (1895); *Souvenirs sur Madame de Maintenon* (with G. Hanotaux, 3 vols. 1902-04); *Ombres françaises et visions anglaises* (1913).

HAUTE-GARONNE, a frontier department of south-western France, formed in 1790 from portions of the provinces of Languedoc (Toulousain and Lauraguais) and Gascony (Comminges and Nébouzan). Pop. (1926) 431,505. Area, 2,458 sq.m. It is bounded north by the department of Tarn-et-Garonne, east by Tarn, south-east by Aude and Ariège, south by Spain and west by Gers and Hautes-Pyrénées. Quaternary and Tertiary deposits occupy the centre of the department. Towards the south the land rises gradually to the Pyrenees, which on the Spanish border exceed 10,000 ft. Two passes, the Port d'Oo and the Port de Vénasque, exceed 9,800 and 7,900 ft. respectively. The Garonne flows in a northerly direction and receives the Pique, the Salat, the Louge, the Ariège, the Touch and the Save. Except in the mountains the climate is mild, the mean annual temperature being rather higher than at Paris. The rainfall, which averages 24 in. at Toulouse, exceeds 40 in. in the mountains; and sudden inundations of the Garonne cause much damage. Thick forests of oak, fir and pine furnish timber for shipbuilding. Wheat, maize and other grains are the principal crops, and there is generally a surplus for export. Market-gardening flourishes around Toulouse. Vineyards are extensive, though the wine is of medium quality; and chestnuts, apples and peaches are grown. Cattle and sheep are reared and co-operative dairies are numerous in the mountains; but deforestation has tended to reduce the area of pasture-land, the soil, unretained by tree roots, having been gradually washed away. Haute-Garonne has deposits of zinc and lead, and salt-workings; there is an ancient marble-working industry at St. Bât. The mineral springs of Bagnères-de-Luchon Encausse, Barbazan and Salies-du-Salat are well known. Manufactures include iron and copper goods, woollen, cotton and linen goods, leather, paper, boots and shoes and tobacco. The main line of the Southern railway from Bordeaux to Cette passes through Toulouse. The Canal du Midi traverses the department for 32 m. and the lateral canal of the Garonne for 15 m. The Garonne is navigable below its confluence with the Salat. There are two arrondissements—Toulouse and St. Gaudens—subdivided into 39 cantons and 589 communes. Toulouse is the seat of a court of appeal and of an archbishop, the headquarters of the XVII. army corps and the centre of an academy; and St. Gaudens, Bagnères-de-Luchon and St. Bertrand-de-Comminges are important. St. Aventin, Montsaunès and Vènerque possess old churches in the Romanesque style. The choir of St. Just at Valcabrière dates from the 8th or 9th century and part of the nave from the 11th century. There are ruins of a Cistercian abbey at Bonnefont near St. Martory. Gallo-Roman remains have been discovered at Martres. Near Revel is the reservoir of St. Ferréol, constructed for the canal du Midi in the 17th century.

HAUTE-LOIRE, a department of central France, formed in 1790 of Velay and portions of Vivarais and Gévaudan, three districts formerly belonging to the old province of Languedoc, of a portion of Forez formerly belonging to Lyonnais, and a portion of lower Auvergne. Pop. (1926) 260,610. Area, 1,931 sq.m. It is bounded north by Puy-de-Dôme and Loire, east by Loire and Ardèche, south by Ardèche and Lozère and west by Lozère and Cantal. Forming a portion of the Plateau Central, it is traversed from north to south by four mountain ranges. Its highest point, the Mont Mézenc (5,755 ft.), in the south-east, belongs to the mountains of Vivarais, which are continued along the eastern border by the Boutières chain. The Lignon divides the Boutières from the Massif du Mégal, which is separated by the Loire from the

mountains of Velay, a granitic range overlaid with volcanic rocks. The Margeride mountains run along the western border. The Loire waters the eastern half of the department. The Allier, which joins it at Nevers, traverses the western portion. The chief affluents of the Loire within the department are the Borne on the left, joining it near Le Puy, and the Lignon, on the right. The winters are long and rigorous. Rye, oats, barley and wheat are cultivated and aromatic and medicinal plants are abundant on the plateaus. Lentils, peas, mangelwurzels and other forage and potatoes are also grown. Horned cattle belong principally to the Mézenc breed; goats are numerous. The woods yield pine, fir, oak and beech. Lace-making and coal-mining (around Brassac and Langeac) are main industries. There are also mines of antimony and stone-quarries. Silk-milling, caoutchouc-making, paper-making, glass-blowing and wood-sawing are also carried on. The principal imports are flour, brandy, wine, live-stock, lace-thread and agricultural implements. Exports include fat stock, wool, aromatic plants, coal, lace. The department is served chiefly by the Paris-Lyon-Méditerranée company. There are two arrondissements—Le Puy and Brioude—with 28 cantons and 266 communes.

Haute-Loire forms the diocese of Le Puy in the ecclesiastical province of Bourges, and belongs to the académie (educational division) of Clermont-Ferrand. Its court of appeal is at Riom. The churches of Chamalières, St. Paulien and Sainte-Marie-des-Chazes are Romanesque in style; Le Monastier preserves the church, in part Romanesque, and the buildings of the abbey to which it owes its origin. Arlempdes and Bouzols (near Coubron) have the ruins of large feudal châteaux. The rocky plateau overlooking Polignac is occupied by the ruins of the stronghold of the ancient family of Polignac, including a square donjon of the 14th century. Interesting Gallo-Roman remains have been found on the site.

HAUTE-MARNE, a department of north-eastern France, made up of districts belonging to the former province of Champagne (Bassigny, Perthois, Vallage), with smaller portions of Lorraine and Burgundy, and some fragments of Franche-Comté. Area, 2,415 sq.m. Pop. (1926) 195,370. It is bounded north-east by Meuse, east by Vosges, south-east by Haute-Saône, south and south-west by Côte d'Or, west by Aube, and north-west by Marne. Its greatest elevation (1,693 ft.) is in the plateau of Langres between the sources of the Marne and those of the Aube; the watershed between the Rhone and the Seine and Meuse, formed by the plateau of Langres continued north-east by the Monts Faucilles, has an average height of 1,500 or 1,600 ft. To the north is Bassigny (the *paybas* or low country, as distinguished from the highlands), a district characterized by monotonous flats of little fertility and extensive wooded tracts. The principal river of the department is the Marne. It receives on the right the Rognon, and on the left the Blaise. The western portion is watered by the Aube and its tributary the Aujon, both of which have their sources on the plateau of Langres. The Meuse rises in the Monts Faucilles, and has a course of 31 m. within the department. The Apance, the Amance, the Salon and the Vingeanne are tributaries of the Saône. The mean temperature is 51° F, nearly that of Paris; the rainfall is slightly below the average for France.

Agriculture is carried on by small proprietors. The chief crops are wheat and oats; potatoes, lucerne and mangel-wurzels are next in importance. Horse and cattle-raising flourish in Bassigny. The white wine of Soyers is notable. The department is rich in iron and building stone is quarried. The warm springs of Bourbonne-les-Bains are among the earliest known and most frequented in France. Industrial establishments include blast furnaces, foundries, forges, plate-rolling works, and shops for nail-making and smith's work of various descriptions. St. Dizier is the chief centre of manufacture and distribution. The cutlery trade is important at Nogent-en-Bassigny and in the neighbourhood of Langres. Val d'Osne is well known for its metal-work. Flour-milling, glove-making (at Chaumont), basket-making and tanning are also carried on. The principal import is coal, while manufactured goods, iron, stone, wood and cereals are exported. The line of the Eastern railway from Paris to Belfort passes through Chaumont and Langres. The canal from the Marne to the Saône

and that of the Haute-Marne together cover 99 m.; there is a canal 14 m. long from St. Dizier to Wassy. There are two arrondissements (Chaumont and Langres), with 28 cantons and 550 communes. Chaumont is the capital. The department forms the diocese of Langres; it belongs to the VII. military region and to the educational circumscription (académie) of Dijon, where also is its court of appeal. At Montier-en-Der the remains of a 7th century abbey include a church with nave and aisles of the 10th, and choir of the 13th century. Wassy, the scene of the massacre of Protestants in 1562, has a church largely of the Romanesque period. Vignory has a church of the 11th century. Joinville, a metallurgical centre, preserves a château in the Renaissance style. Pailly, near Langres, has a late 16th century château.

HAUTES ALPES, a department in south-east France, formed in 1790 out of the south-eastern portion of the old province of Dauphiné, together with a small part of north Provence. It is bounded north by the department of Savoie, east by Italy and south and south-east by the department of the Basses Alpes, south by the last-named department, and west by the departments of the Drôme and of the Isère. Its area is 2,178 sq.m. Pop. (1926) 87,963. It is very mountainous and includes the Pelvoux mass of Primary rocks rising to a height of 12,973 ft. in the north, the high line of the Cothian alps 12,609 ft. in the east, and the Papillon mountains of Mesozoic rocks in the south. The department consists of the basins of the upper Durance (with tributaries, Guisane, Gyronde and Guil), of the upper Drac, leading to Grenoble, and of the Buëch. The department is divided into two arrondissements (Gap and Briançon), 24 cantons and 186 communes. Pop. (1926) 87,963. There are no large industries and commerce is almost wholly local. The prolonged winter greatly hinders agricultural development, while the pastoral region has been greatly damaged and forests destroyed by the ravages of Provençal sheep, vast flocks of which are driven up here in the summer, as the pastures are leased out to a large extent, and but little utilized by the inhabitants. It now forms the diocese of Gap (this see is first certainly mentioned in the 6th century) in the ecclesiastical province of Aix en Provence; in 1791 there was annexed to it the archiepiscopal see of Embrun, which was then suppressed. There are 114 m. of railway in the department. This includes the main line from Briançon past Gap towards Grenoble. About 16½ m. west of Gap is the important railway junction of Veynes, whence branch off lines to Grenoble, to Valence by Die and Livron, and to Sisteron for Marseilles. The chief town is Gap; Briançon and Embrun are the other towns.

HAUTE-SAÔNE, a department of eastern France, formed in 1790 from the northern part of Franche Comté. It is traversed by the river Saône, bounded north by the department of the Vosges, east by the territory of Belfort and the department of Haut-Rhin, south by Doubs and Jura and west by Côte-d'Or and Haute-Marne. Pop. (1926) 226,313; area, 2,075 square miles. The department is the upper basin of the Saône from the Ballon de Servance (3,970 ft.) in the north-east to its confluence with the Ognon in the south-west, and it also includes the right side of the lower Ognon valley extending over to the left side in the upper part of that valley towards Belfort. The sandstones and granite of the southern Vosges give place to limestones framing the two valleys at a level of 800–1,000 ft., and the water that soaks through these limestones emerges as springs feeding the streams in the valleys 200 ft. lower down. The north-eastern districts are cold, due in part to the coldness of the soil, and have an annual rainfall ranging from 36 to 48 inches. Towards the south-west the climate becomes more temperate. At Vesoul and Gray the rainfall reaches only 24 in. per annum.

Half of the area of Haute-Saône is arable land, growing wheat, oats, meslin and rye and potatoes. The vine flourishes mainly in the arrondissement of Gray; tobacco is grown. Apples, plums and cherries (from which the kirsch, for which the department is famous, is distilled) are the chief fruits. The woods which cover a quarter of the department are composed mainly of firs in the Vosges and of oak, beech, hornbeam and aspen elsewhere. Horses and horned cattle thrive on the river pastures. Mines of coal (at Ronchamp) and rock-salt (at Gouhenans), and stone quarries

are worked. The hot springs of Luxeuil (*q.v.*) are the most famous of the department. There are iron-working establishments, copper-foundries, engineering works, steel-foundries and factories at Plancher-les-Mines and elsewhere for producing iron-mongery, nails, pins, files, saws, screws, shot, chains, agricultural implements, locks, spinning machinery, edge tools, glass-works, potteries and brick and tile-works, cotton factories, of which Héricourt (pop. in 1926, 4,897) is the chief centre, paper-mills, print-works, fulling mills, hosiery factories and straw-hat factories, as well as sugar works, distilleries, dye-works, saw-mills, starch-works, the chemical works at Gouhenans, oil-mills, tan-yards and flour-mills. The department exports wheat, cattle, cheese, butter, iron, cotton-cloth, wood, pottery, kirschwasser, plaster, leather, glass, etc. The Saône provides a navigable channel of about 70 m., which is connected with the Moselle and the Meuse at Corre by the Canal de l'Est along the valley of the Coney. Gray is the chief emporium of the water-borne trade of the Saône. Haute-Saône is served chiefly by the Eastern railway. There are two arrondissements—Vesoul and Lure—comprising 28 cantons, 583 communes, Haute-Saône is in the district of the VII. army corps (Besançon), and in its legal, ecclesiastical and educational relations depends on Besançon.

Vesoul, the capital of the department, Gray, Lure and Luxeuil are the principal towns. The Roman ruins and mosaics which may be seen at Membrey, and the church (13th and 15th centuries) and abbey buildings in and around Faverney (10th, 13th and 14th centuries), in the arrondissement of Vesoul, are of anti-quarian interest.

HAUTE-SAVOIE, a frontier department of France, formed in 1860 of the old provinces of the Genevois, the Chablais and the Faucigny, previously the northern portion of the duchy of Savoy neutralised in 1815. It is bounded N. by the canton and Lake of Geneva, E. by the Swiss canton of the Valais, S. by Italy and the department of Savoie, and W. by the department of the Ain. Pop. (1926) 245,317. Area, 1,775 sq.m. It slopes from the Mont Blanc (15,782 ft.) chain on the south-east down to the lake and canton of Geneva and the Rhone (945 ft.) on the west. It is drained by many streams, the chief of which are the Arve and the Fier, feeders of the Rhone; the Fier forms the lake of Annecy. The climate varies considerably with the altitude; the maximum rainfall is in May and June. The tourist industry is highly important, especially at Chamonix. Cattle and poultry are reared, and Gruyère cheeses and honey are made. There are chalybeate springs at Évian and Amphion, and at St. Gervais and elsewhere. Anthracite and asphalt mines are numerous, as well as stone quarries. There is much trade in pine and other wood from mountain forests. Cotton is manufactured at Annecy, Cluses is the centre of the clock-making industry, and there is a well-known bell foundry at Annecy le Vieux. The department is divided into three arrondissements (Annecy, the principal town, Bonneville and Thonon), 28 cantons and 315 communes. It forms the diocese of Annecy in the province of Chambéry, is in the district of the XIV. army corps (Lyons) and in the Académie (educational division) of Chambéry, where is its court of appeal. Thonon (the old capital of the Chablais) is the chief town on the south shore of the Lake of Geneva and, after Annecy, the largest place in the department.

HAUTES-PYRÉNÉES, a department of south-western France, on the Spanish frontier, formed in 1790, half of it being taken from Bigorre and the remainder from Armagnac, Nébouzan, Astarac and Quatre Vallées, districts of the province of Gascony. Pop. (1926) 187,875. Area, 1,750 sq.m. Hautes-Pyrénées is bounded south by Spain, west by the department of Basses-Pyrénées, north by Gers and east by Haute-Garonne. The south of the department, comprising two-thirds of its area, is occupied by the central Pyrénées composed of palaeozoic rocks with mesozoic rocks on the northward facing slopes. The ancient volcanic rocks stand out as the highest peaks, some exceeding 10,000 ft., the Vignemale (10,820 ft.) being the highest in the French Pyrénées. The imposing *cirques* (Cirques de Troumouse, Gavarnie and Estaubé), with glaciers and waterfalls, and the pleasant valleys attract many tourists. The north of the department has plains and

undulating hills clothed with cornfields, vineyards and meadows. To the north-east, the cold and wind-swept plateau of Lannemezan (about 2,000 ft.) with miocene and glacial deposits, presents a striking contrast to the plain below. The Adour and its tributary, the Gave de Pau, and the Neste, an affluent of the Garonne, drain the department. The sources of the second and third lie close together in the Cirque of Gavarnie. An important section of the Pyrenees, which carries the Massif Néouvielle and the Pic du Midi de Bigorre runs northward between these two valleys. The Adour descends from the Pic du Midi through the Campan valley and leaves the mountains at Bagnères and then divides into a multitude of channels, notably the Canal d'Alaric (36 m. long), to irrigate the rich plain of Tarbes. Beyond Hautes-Pyrénées it receives the Arros, which flows through the department from south to north-west; on the left it receives the Gave de Pau; it is navigable in the lower stretches. The Gave de Pau, larger than the upper Adour, after passing Argelès, a well-known centre for excursions, and Lourdes, leaves the mountains. The Neste is important as furnishing the plateau of Lannemezan with a canal, the Canal de la Neste, the waters of which are partly used for irrigation and partly for supplying the streams that rise there and are dried up in summer—the Gers and the Baise, affluents of the Garonne. The climate of Hautes-Pyrénées, cold on the highlands, gives on the plains, hot summers, fine autumns, mild winters and rainy springs. On the plateau of Lannemezan, summers are dry and scorching, winters very severe. The average annual rainfall at Tarbes, in the north, is about 34 in.; at the higher altitudes it is much greater. The mean annual temperature at Tarbes is 59° Fahr.

Hautes-Pyrénées is agricultural in the plains, pastoral in the highlands. The more important cereals are wheat and maize, chiefly in the Adour valley, and the northern part of the department, which is much used for the feeding of pigs and poultry, especially geese; rye, oats and barley are grown in the mountain districts. The wines of Madiran and Peyriguère are well known and chestnut trees and fruit trees are grown on the lower slopes. Horse breeding is important around Tarbes and Bagnères-de-Bigorre and there is a famous stud at Tarbes. The horse of the region has Arab, English and Navarrese blood and is well fitted for saddle and harness. Cattle raising is important; the milch-cows of Lourdes and the oxen of Tarbes and the valley of the Aure are highly esteemed. Sheep and goats are also reared. The forests, which occur chiefly in the highlands are mainly coniferous and still contain wild animals (bears, wolves, etc.). There are at Campan and Sarrancolin quarries of fine marble, which is sawn and worked at Bagnères. There is a group of slate quarries at Labassère and an important slate works at Tarbes. Deposits of lignite, lead, manganese and zinc are found. The principal mineral springs in the valley of the Gave de Pau are Cauterets (hot springs containing sulphur and sodium), St. Sauveur (springs with sulphur and sodium), and Barèges (hot springs with sulphur and sodium), and in the valley of the Adour Bagnères (hot or cold springs containing calcium sulphates, iron, sulphur and sodium) and Capvern near Lannemezan (springs containing calcium sulphates).

The department has flour-mills and saw-mills, a large military arsenal at Tarbes, paper-mills, tanneries and manufactories of agricultural implements and looms. The spinning and weaving of wool are carried on chiefly at Bagnères-de-Bigorre.

Of the passes (*ports*) into Spain, even the chief, Gavarnie (7,398 ft.), is not accessible to carriages. The Southern railway main line from Bayonne to Toulouse, traverses the department. There are two arrondissements, those of Tarbes and Bagnères-de-Bigorre, 26 cantons and 480 communes. Tarbes is the capital of Haute-Pyrénées, which is attached to the appeal court of Pau and forms part of the region of the XVIII. army corps (Bordeaux). There are bishops at Tarbes and Lourdes, under the archbishop of Auch. The department is in the académie (educational division) of Toulouse. Tarbes, Lourdes, Bagnères-de-Bigorre and Luz-St. Sauveur are the principal towns. St. Savin, in the valley of the Gave de Pau, and Sarrancolin have interesting Romanesque churches. The church of Maubourguet was built by the Templars in the 12th century.

HAUTE-VIENNE, a department of central France, formed in 1790 of Haut-Limousin and of portions of Marche, Poitou and Berry. Pop. (1926) 351,311. Area, 2,119 sq.m. It is bounded north by Indre, east by Creuse, south-east by Corrèze, south-west by Dordogne, west by Charente and north-west by Vienne. The highest altitude (2,549 ft.) is in the extreme south-east, and belongs to the treeless but well-watered plateau of Millevaches, formed of granite, gneiss and mica. From that point the department slopes towards the west, south-west and north. To the north-west of the Millevaches are the Ambazac and Blond Hills, and the mountains of Limousin are on the south. The Vienne traverses the department from east to west, forming in its upper course the basin of Limoges, passing Eymoutiers, St. Léonard, Limoges and St. Junien, and receiving most of its tributaries from the south. The altitude, inland position and cold soils of Haute-Vienne and the northern exposure of its valleys make the winters long and severe; but the climate is milder in the west and north-west. The annual rainfall often reaches 36 or 37 in. and even more in the mountains. Rye, wheat, buckwheat and oats are the cereals most grown, but the chestnut still forms the staple food of large numbers. Potatoes, walnuts and cider-apples are cultivated. Good breeds of horned cattle and sheep are reared in the valleys and find a ready market in Paris. Horses for remount purposes are also raised. The quarries furnish granite and large quantities of kaolin, which is both exported and used in the porcelain works of the department. Limoges is a centre of the porcelain industry and has important liqueur distilleries. Agricultural implements and hats are other industrial products, and there are breweries, dye-works, tanneries, iron foundries and printing works. Wine and alcohol for liqueur-manufacture, coal, raw materials for textile industries, hops, skins and various manufactured articles are among the imports.

The department is served by the Orléans Railway. It is divided into the arrondissements of Limoges, Bellac and Rochechouart (29 cantons and 205 communes), and belongs to the académie (educational division) of Poitiers and the ecclesiastical province of Bourges. Limoges, the capital, is the seat of a bishopric and of a court of appeal, and the headquarters of the XII. army corps. The other principal towns are St. Yrieix and St. Junien. Solignac, St. Léonard and Le Dorat have fine Romanesque churches. There are important remains of the château of Chalusset (S.S.E. of Limoges), and the château of Rochechouart dates from the 13th, 15th and 16th centuries.

HAUT-RHIN, department of France, formed after the Revolution in 1790 from the southern portion of Alsace, and incorporated in 1870 with the German empire; it was resuscitated by the Treaty of Versailles in 1918, when Alsace-Lorraine became French once more. It is bounded north by Bas-Rhin, east by the State of Baden, south by Switzerland, south-west by the territory of Belfort and west by the Vosges. Pop. (1926), 490,654.

The department which is 1,354 sq.m. in area occupies the southern portion of the Rhine trough. The Vosges and Black Forest are the remains of a Hercynian block, rifted, apparently, at some stage in the uprise of the Alps, with the result that the deep Rhine trough from Basle northwards was formed. Loess deposits occur in the south and along the foot of the Vosges, and give good soil, with layers useful for the manufacture of bricks. Haut-Rhin is one of the most fertile parts in central Europe. The hills are richly wooded, chiefly with fir, beech and oak. The agricultural products are corn, potatoes, flax, grapes and other fruit. Cotton spinning and weaving is the most important industry centred in Mulhouse, Colmar, Guebwiller, and the Vosges valleys. Other industries are the manufacture of woollen and silk goods, chemicals, paints, machinery, pottery, bricks, tiles and paper. Potash is produced near Mulhouse, and also lime. Haut-Rhin is also important for its wine.

Haut-Rhin is at a disadvantage as regards commerce, owing to its isolation from the rest of France, and the fact that the Rhine, its main outlet, has its mouth outside France. The Rhine is navigable for small vessels as far as Basle, but the department is served by the Ill; the Rhine-Rhone canal is another outlet. This department and Bas-Rhin, however, gain from the fact that

they are in the French customs boundary, and thus have French markets open to their industrial products.

Colmar is the capital of the department, which includes six arrondissements (Colmar, Altkirch, Guebwiller, Mulhouse, Ribeauville, and Thann), 26 cantons, and 385 communes. It is under the académie of Strasbourg. Colmar is the seat of Superior Regional Tribunal. It is the bishopric of Strasbourg. The other important towns are Mulhouse, Guebwiller, and Altkirch. Most of the towns are situated on the Ill; there are no important towns on the Rhine south of Strasbourg, owing to its marshy banks. The department is served by the rail from Basle via Mulhouse and Colmar to Strasbourg.

HAÜY, RENÉ JUST (1743-1822), French mineralogist, was born at St. Just, Oise, on Feb. 28, 1743. An accident directed his attention to crystallography. Happening to let fall a specimen of calcareous spar, he was led by examination of the fragments to make experiments which resulted in the statement of the geometrical law of crystallization associated with his name (see CRYSTALLOGRAPHY). The value of this discovery, the mathematical theory of which is given by Haüy in his *Traité de minéralogie*, was immediately recognized, and when communicated to the Academy, it secured for its author a place in that society. Haüy's name is also known for the observations he made in pyro-electricity. When the Revolution broke out, he was saved by the intercession of E. Geoffroy Saint-Hilaire. In 1802, under Napoleon, he became professor of mineralogy at the museum of natural history, but was deprived at the Restoration. He died in Paris on June 3, 1822.

Among his numerous works may be mentioned *Tableau comparatif des résultats de la cristallographie, et de l'analyse chimique relativement à la classification des minéraux* (1809); *Traité des pierres précieuses* (1817); *Traité de cristallographie* (2 vols., 1822). He also contributed papers, of which 100 are enumerated in the Royal Society's catalogue, to various scientific journals, especially the *Journal de physique* and the *Annales du Muséum d'Histoire Naturelle*.

HAVANA or HABANA, capital and commercial metropolis of the Republic of Cuba, the largest city of the West Indies and one of the most progressive tropical cities in the New World, lies on the northern coast of the island of Cuba, toward the western end, at 23° 9' N. lat. and 82° 22' W. long. The population was 235,981 in 1899, the year following independence, and 562,968 in

Physical Appearance and Transport.—Havana occupies a peninsula west of the harbour, Morro castle, a landmark and powerful fortress of the Spanish colonial days, occupying the opposite point of the narrow harbour entrance. This entrance-strait, some 230 metres wide and 1,400 metres long, leads to the inner harbour, which lies east and south of the city, whose water front in the older sections is lined with wharves and docks, to which ocean-plying ships tie up and unload. There are three distinct arms of the inner bay, called, respectively, Marimaleña or Regla bay, Guanabacoa bay and the Bay of Atares. About three-quarters of the imports and a large portion of the exports of the island pass through Havana, and shipping from every country of the world centres there. It is now the terminus of the train ferry from the United States carrying loaded cars of freight to and from Key West. The passage of this train ferry occupies six hours from the United States port to the Cuban, and a large proportion of the perishable freight between the two countries travels by this unique route; a similar train ferry is to connect Havana and New Orleans. Havana is also the terminus of the air-mail and passenger planes from the United States and an important station in the air-mail connection from the United States south-eastward to Haiti, Santo Domingo, Porto Rico and the lesser Antilles and, west and south, via Yucatán and Central America, to the Panama Canal Zone.

The aspect of Havana from the sea is striking and picturesque. The suburbs, with beautiful residences and country clubs, lie along the seacoast, and at the entrance of the harbour, the Morro, with its picturesque lighthouse rises to the left, while on the right the city, built of the white coral limestone of the West Indies, rises on either side of the superb avenue, properly called the Paseo de Martí, but commonly known by its old Spanish name of the Prado. The lower Prado is lined with residences, but the so-called Upper Prado leads to the Parque Central on one side of which has been built the pretentious and costly new Legislative Palace, begun by President José Miguel Gomez about 1910 and finished under President Gerardo Machado in 1929.

Streets and Buildings.—From well out toward the western suburbs, the Malecón, or sea wall, a wide avenue which skirts the sea and city, has furnished a colourful foreground which now is extended along inside the harbour, on reclaimed ground which covers the shallows of the harbour entrance, and creates wide parks and valuable commercial lands. The Malecón merges at the Prado into the new Avenida del Puerto, which with a width varying from 15 to 37 metres, connects this outer drive to the old, narrow streets of the business section. This new entrance to the old business streets of O'Reilly, Obispo (Pi y Margall) etc., has wiped out much of the old down-town congestion. Most of the old streets of Havana, laid out to furnish shade along their narrow drives and walks and to carry only a few dozen old fashioned Cuban coaches (*quitrines* or *volantas*) now carry the hundreds of automobiles in one direction only, giving a more ordered control of the traffic problem.

Many new public buildings are being built along the Malecón and the Avenida del Puerto, including the handsome Capitania, or office of the captain of the port and the new section has also a number of fine parks, notably the Parque del Maine, with its handsome monument dedicated to the American battleship "Maine," which was blown up in Havana harbour on Feb. 15, 1898. Another recent and important public building is the Presidential palace, the residence of the chief executive, at the head of the Avenida de las Misiones, a wide new thoroughfare; this avenue leads from Avenida del Puerto inland, and is designed to be lined for its short length with the embassies and legations of foreign Governments.

Old Landmarks.—Of the older landmarks, one of the most important is the old palace of the Spanish governors, now the office of the Ayuntamiento or city government; this fine old pile stands on the site of the original parish church, on the eastern side of the Plaza de Armas, the old centre of the colonial city. The palace was erected in 1773-92 and remodelled in 1835 and 1851. It was the scene of the surrender by the Spaniards of the sovereignty of the island to the United States at the close of the

WEATHER GRAPH OF HAVANA. THE MERCURY STANDS AT THE NORMAL ANNUAL MEAN TEMPERATURE; THE CURVE SHOWS THE NORMAL MONTHLY MEAN TEMPERATURE, AND THE COLUMNS INDICATE THE NORMAL MONTHLY PRECIPITATION

1927. Havana is the seat of the Federal executive, of the national Congress and of the Supreme Court of the nation. It boasts one of the finest natural harbours of the Caribbean region, completely protected and accessible to ships of virtually any draught. In recent years the city has undergone a wide-spread change to modernity, the narrow harbour entrance as well as the outer shore have been flanked by a broad avenue, important streets have been cut through the older city, and the narrow centre, for some years unimaginably congested with motor traffic, has been made more easily accessible to the outer suburbs and the newer sections.

Spanish-American War and the scene, too, of the transfer of its sovereignty from the United States to the first president of Cuba, Tomás Estrada Palma, on May 20, 1902.

The most precious of the old historical landmarks, however, is the ancient stronghold, La Fuerza, or more properly, El Castillo de la Real Fuerza, begun in 1565 and completed in 1583, standing on the site of the yet older fortress built by order of Hernando de Soto in 1538, but destroyed by the French pirate Jacques de Sores. The present fortress was from 1584 until the middle of the 18th century the home of the governors general and the citadel and refuge of the populace in times of danger. Crowning the old watch-tower of La Fuerza is a weather vane formed in the shape of a woman, called "La Habana" or "The Havana," the origin of a local adage that "Many have visited Havana who have not seen The Havana." Another old building is that used by the senate, of elaborate 18th century Spanish baroque architecture, recently restored. The old city also contains the post office (the church of San Francisco), begun in 1575 and rebuilt in 1731-37. Also the old municipal jail, a typical Spanish fortress on the Prado, and the Castillo del Príncipe, now the penitentiary. In this section also is the national library, the Maestranza, formerly the navy yard and the headquarters of the artillery. The old city abounds, also, in ancient private residences, many of them now in the hands of the Government or patriotic societies, which preserve and have restored them with appreciative care.

Many of the present public buildings were formerly churches, and indeed churches of the colonial epoch are still amongst the most interesting and carefully preserved relics of the older days. The convent of Santa Clara, built in 1644, was in 1928 bought by the Government at a substantial price and converted into the ministry of public works; in the large patio of this old building are still preserved the first houses and streets built in Havana, as they were enclosed in the old church and monastery by its builders in the 17th century. The cathedral is the most noteworthy, architecturally, of the city's churches; it was originally the Jesuit church, erected between 1656 and 1724, although the interior decorations date only from 1790-1820. One of the tombs of Columbus is marked here; the remains of the discoverer were removed, according to certain claimants, from Santo Domingo in 1796, and lay here until carried to Spain in 1898. (See COLUMBUS, also SANTO DOMINGO, for the Dominicans claim that Columbus's bones still lie in their ancient cathedral.) Other fine old churches of Havana, like Santo Domingo (1578), Santa Catalina (1700), San Agustín (1618), La Merced (1744), San Felipe (1693) and Belén (1704), have suffered from the ravages of time and have gone or will go soon, to make way for new business structures.

Parks and Suburbs.—Havana has been famous since the days of the Spaniards for its parks and drives. The harbour's edge on the east is traversed in part by the old Paseo or Alameda de Paula, originally laid out in 1772, and by the new Avenida del Puerto, the latter a portion of the elaborate modern reconstruction of Havana (including the opening of the Avenida de las Misiones and the beautification of the Prado), designed and carried out under Dr. Carlos Miguel de Céspedes, while minister of public works under President Gerardo Machado. The Malecón or sea wall drive, now extended around the harbour entrance as the Avenida del Puerto, traverses the edge of the city along the sea for several miles, a beautiful drive and promenade. The Prado, rechristened the Paseo de Martí in honour of the "Apostle of Cuban independence," follows the line of the old city wall, past the Parque Central to the Plaza de la Fraternidad, formerly Parque de Colón or Campo de Marte. The Prado is lined with handsome homes and clubs. It curves in its course and furnishes a highway into the heart of the old city, although its formal climax is the Parque de Colón, where stand handsome monuments to José Martí and other Cubans notable in history and science. This park is surrounded by handsome offices, hotels and clubs, among them the more elaborate and costly Centro Asturiano one of the two large Spanish clubs, the other being the Casino Español, 60,000 members. In this section are most of the half-dozen very modern and handsomely equipped hotels that make Havana an

important winter resort.

From Plaza de la Fraternidad, the Avenida de Simón Bolívar, formerly Calzada de la Reina, reaches the Paseo de Carlos III. and the Paseo de Tacón, passing westward through the city to the botanical gardens and the Quinta de los Molinos to the old citadel of El Príncipe, begun in 1774 and finished 20 years later. Los Molinos was once the summer palace of the Spanish governors general and now adjoins the gardens of the university, whose fine modern buildings were dedicated by their use for the Sixth Pan American Conference in 1928. Near El Príncipe is the Colón cemetery, with many historic monuments and handsome mausoleums. Another famous promenade and drive is the Avenida de Menocal, at the west end of the new city; the Cerro, in the southwest, is a handsome residence quarter, with many elaborate homes.

Suburban growth in Havana has been rapid and extensive, the whole territory now tributary to the capital, thanks to good roads and automobile traffic, covering a large area. On the south and west the city is surrounded by a range of hills, with the conspicuous fortifications of Castillo del Príncipe on the west. Lower down on the hills are the suburbs of Venado, Jesús del Monte and Luyana; besides these Puentes Grandes, old Marianao and Guanabacoa are healthy and populous suburbs; along the sea-coast, baths excavated in the coral rock mark clubs and resorts; such baths make swimmers safe from sharks.

Charities and Education.—As Havana was, and is, the chief centre of political and commercial life of Cuba, so its charities and educational facilities are the most complete in the island. Ancient foundations compete with modern institutions, in the former category, the Casa de Beneficencia y Maternidad (charity and maternity hospital), dating from 1794, while the Club Asturiano, one of the richest of the modern Spanish clubs, has its own modern sanitarium in the midst of the city. The university is the most important and its buildings the most modern of the educational facilities of the capital, but there are fine secondary schools, a fairly complete system of primary education, virtually all of it built since independence, and some notable Roman Catholic schools. Libraries are improving. The Sociedad Económica de los Amigos del País, founded in 1792, has one of nearly 50,000 vol., and the National library, dating only from 1901, over 100,000, including donations from historical sources.

The newspapers of Havana are modern, progressive and numerous. The *Diario de La Marina* is the oldest, having been founded in 1838. *El Mundo* is a powerful younger rival in the morning field, while the evening papers, though less formal than the morning press, are influential and enjoy wide circulation.

Population and Health.—Havana has grown steadily since its foundation, boasting 51,307 people in 1791; 96,304 in 1811; 94,023 in 1817; 184,508 in 1841; 235,981 in 1899, the year following independence; 360,517 in 1919; 432,353 in 1925; 562,968 in 1927. In 1929 it was estimated to have 650,000 and with the suburbs and tributary territory close to a million. The 1899 census, made by the U.S. administration, showed 25% of the population foreign (20% being Spanish), a figure which probably continues, as there is a heavy immigration from Spain each year, besides the temporary workers who come annually to Cuba (via Havana) for the sugar cutting, and return home to Spain (and Italy) when it is done.

The workers' residence portion of the city is congested, and before the American occupation, health conditions were notoriously bad and deaths from epidemics, including periodic scourges of yellow fever, rose to high figures. One of the worst of the yellow fever epidemics broke out in 1900, immediately following the War of Independence, and concomitant with a heavy immigration from Spain. Stringent sanitary regulations failed to stop the epidemic, and the efforts of the American army surgeons to locate the method of transmission of yellow fever led directly to the discovery of the part played by the *stegomyia* mosquito; Maj. Walter Reed, of the U.S. army, gave his life through voluntary infection with yellow fever through a mosquito bite to prove the theory. Maj. William C. Gorgas (*q.v.*), later the sanitary officer who cleaned up the Panama Canal Zone, led the fight that practically exterminated the mosquitoes of Havana and ended yellow

VIEWS OF HAVANA AND ITS HARBOUR

1. Havana, the capital of Cuba, as seen from Morro Castle across the entrance to the harbour. The wide street which runs through the centre of the city at right angles to the water front is the Prado
2. A closer view of the Prado, one of the finest of the residential streets. Here, as in other parts of the city, the white coral limestone of the West Indies is generally used for building material
3. View of the harbour front of Havana
4. From Havana looking across the harbour entrance-strait to Morro Castle, a fortress built by the Spaniards in the late 16th century
5. Air view of the lower portion of Havana, showing the Malecon, or sea wall. It is built on reclaimed ground which covers the shallows of the harbour entrance, creating wide parks and additional land for commercial purposes. A wide avenue extends along the harbour from the western suburbs to the Prado

fever epidemics. Havana is now one of the most carefully protected ports in the world, so far as sanitary measures are concerned, and its death rate has long since been reduced to normal proportions. Recent changes in the water system, with additions of new reservoirs, has brought the excellent water from the hills into the capital and the fetid Havana of the colonial period is now a memory only.

Communications.—Havana is the terminus of the chief railways of the island, every community of the republic seeking communication with the capital. It is also the focus of the important new Central highway, extending the length of the island, with Havana as the radiating centre of the two branches east and west; the highway was begun in 1927, to be completed in 1930, of solid concrete base, concrete bridges and surfaced with asphalt composition. Havana also has the most complete steamship service with the outside world, being a principal stop for passenger liners to and from the Panama Canal and the Caribbean region, and in touch with United States and European ports by direct lines. Cable, telephone and radio link it to the outside world.

History.—Havana was founded in 1514 by Diego Velázquez in an unhealthy site now occupied by the town of Batabaño, but was early removed to its present site and rapidly assumed an increasing importance in the Spanish colonies of the New World. In 1634 its important strategic position was recognized by a royal decree declaring it to be the "Llave del Nuevo Mundo y Antemural de las Indias Occidentales." (Key to the New World and Bulwark of the West Indies), and the arms of the town to-day carry the symbolic key and its two fortresses. The town has been the object of numerous attacks by English, French and Dutch pirates. In 1537 it was sacked and burned, in 1555 it was plundered by French buccaneers and in 1856 Sir Francis Drake threatened it; but in 1589 Philip II. of Spain ordered the erection of the Punta and the Morro, the ancient defences, and the residence of the governor of the island was removed from Santiago de Cuba to Havana, which gained the rank of a city in 1592. It is estimated that the population of the city was about 3,000 by 1600 but had doubled by 1655, when many Spaniards fled there from Jamaica after the capture of that island by the English. During the 17th century Havana became the port of rendezvous of the east-bound fleets of Spanish galleons and was thus the object of many attacks by the English, Dutch and French. The port was blockaded four times by the Dutch in the first half of the 17th century and in 1671 the city walls were begun, being completed in 1702. The European wars of the 17th and 18th centuries were marked by various incidents in local history. After the end of the Spanish War of Succession (1713) came a period of comparative prosperity in slave-trading and general commerce. The creation, in 1740, of a monopolistic trading-company was an event of importance in the history of the island. English squadrons threatened the city several times in the first half of the 18th century, but it was not until 1762 that an investment, made by Admiral Sir George Pocock and the earl of Albermarle, was successful. The siege lasted from June to August and was attended by heavy losses on both sides. The British commanders wrung great sums from the church and the city as prize of war and price of good order. By the treaty of Feb. 10, 1763, at the close of the Seven Years' War, Havana was restored to Spain in exchange for the Floridas. The English turned over the control of the city on July 6. Their occupation greatly stimulated commerce, and from it dates the modern history of the city and of the island. The gradual removal of obstacles from the commerce of the island from 1766 to 1818 particularly benefited Havana. At the end of the 18th century the city was one of the seven or eight great commercial centres of the world, and in the first quarter of the 19th century was a rival, in population and in trade, of Río Janeiro, Buenos Aires and New York. In 1789 a bishopric was created at Havana suffragan to the archbishopric at Santiago. From the end of the 18th century Havana, as the centre of government, was the centre of movement and interest. During the administration of Miguel Tacón Havana was improved by many important public works; his name is frequent in the nomenclature of the city.

In general, the history of Havana under the Spaniards, and since independence, has been the history of Cuba. Various pirate raids, the slave traffic in the 18th and 19th centuries, filibustering expeditions in the 19th century, and the war (ushered in by the blowing up of the U.S. battleship "Maine" in Havana harbour, Feb. 15, 1898) between Spain and the United States in 1898-99, all had direct bearing on the history of Havana and the city suffered and triumphed with them. These are noted in the article on Cuba.

Havana, like other cities of the West Indies, has suffered from the hurricanes that scourge that region, the most violent being those of 1768, 1810 and 1846, while in 1907 and again in 1926, Havana suffered severely from notable hurricanes.

BIBLIOGRAPHY.—There is little descriptive data in book form in English, and the most important references are those under the article on Cuba (*q.v.*). In Spanish, there are some valuable works, including the following: J. M. de la Torre, *Lo que fuimos y lo que somos, o la Habana antigua y moderna* (Havana, 1857); P. J. Guiteras, *Historia de la conquista de la Habana, 1762* (Philadelphia, 1856); J. de la Pezuela, *Sitio y rendición de la Habana en 1762* (Madrid, 1859); A. Bachiller y Morales, *Monografía histórica* (Habana, 1883), minutely covering the English occupation (the best account) of 1762-63; María de las Mercedes, comtesse de Merlin, *La Habana* (Paris, 1844). (W. THO.)

HAVANT, a market town, Hampshire, England, 67 m. S.W. from London by rail. Pop. of urban district (1921) 4,402. Warblington, 1 m. S.E. (pop. [1921] 4,083) has a church with traces of pre-Norman work, and some remains of a Tudor castle. Havant lies near the head of Langstone harbour. The church of St. Faith, largely rebuilt in 1875, retains some Early English work. There are breweries and tanneries. The island of Hayling, which lies off the coast, was in the possession of successive religious bodies from the Conquest (when it was given to the Benedictines of Jumièges, near Rouen), until the Dissolution. The church of South Hayling, a seaside resort, is fine Early English.

HAVEL, a river of Prussia, Germany, rising at a height of 223 ft. on the Mecklenburg plateau, 7 m. N.W. of Neu-Strelitz, and after threading several lakes flowing south as far as Spandau. Thence it curves south-west, past Potsdam and Brandenburg, traversing another chain of lakes, and finally continues north-west until it joins the Elbe from the right some miles above Wittenberg after a total course of 221 m. and a total fall of only 158 feet. Its banks are mostly marshy or sandy, and the stream is navigable from the Mecklenburg lakes downwards. Several canals connect it with other rivers. Area of river basin, 10,159 sq. miles.

HAVELBERG, a town in the Prussian province of Brandenburg, on the Havel just above its junction with the Elbe. Pop. (1925) 5,408. Havelberg was formerly a strong fortress and changed hands frequently during the Thirty Years' War. The town was incorporated in 1875, and is built partly on an island in the Havel, and partly on hills on the right bank of the river, on one of which stands the fine Romanesque cathedral dating from the 12th century.

HAVELOCK, SIR HENRY (1795-1857), British soldier, one of the heroes of the Indian Mutiny, the second of four brothers (all of whom entered the army), was born at Ford Hall, Bishop-Wearmouth, Sunderland, on April 5, 1795, the son of a wealthy shipbuilder. Educated at Charterhouse school, he entered the Middle Temple in 1813, studying under Chitty, the eminent special pleader. But in 1815 he took a commission in the Rifle Brigade (95th), procured for him by the interest of his brother William. In 1823, having exchanged into the 21st and thence into the 13th Light Infantry, he followed his brothers William and Charles to India, first qualifying himself in Hindustani under Dr. Gilchrist, a celebrated Orientalist.

At the close of 23 years' service he was still a lieutenant, and it was not until 1838 that, after three years' adjutancy of his regiment, he became captain. Before this, however, he had held several staff appointments, notably that of deputy assistant adjutant-general of the forces in Burma till the peace of Yandabu, of which he, with Lumsden and Knox, procured the ratifications at Ava from the "Golden Foot," who bestowed on him the "gold leaf" insignia of Burmese nobility. In 1828 he published at Serampore *Campaigns in Ava*, and in 1829 he married Hannah Shepherd, daughter of Dr. Marshman. About the same time he

became a Baptist, being baptized by John Mack at Serampore. During the first Afghan war he was present as aide-de-camp to Sir Willoughby Cotton at the capture of Ghazni, on July 23, 1839, and at the occupation of Kabul. After a short absence in Bengal to secure the publication of his *Memoirs of the Afghan Campaign*, he returned to Kabul in charge of recruits, and became interpreter to General Elphinstone. In 1840, being attached to Sir Robert Sale's force, he took part in the Khurd-Kabul fight, in the celebrated passage of the defiles of the Ghilzais (1841) and in the fighting from Tezeen to Jalalabad. Here, after many months' siege, his column in a sortie *en masse* defeated Akbar Khan on April 7, 1842. He was now made deputy adjutant-general of the infantry division in Kabul, and in September he assisted at Jagdalak, at Tezeen, and at the release of the British prisoners at Kabul, besides taking a prominent part at Istaliff. He also served in the Mahratta and Sikh campaigns of 1843 and 1845. After two years spent in England he became (1854), quartermaster-general, then full colonel, and lastly adjutant-general of the troops in India.

In 1857 he was selected by Sir James Outram to command a division in the Persian campaign. Peace with Persia set him free just as the Mutiny broke out; and he commanded a column "to quell disturbances in Allahabad, to support Lawrence at Lucknow and Wheeler at Cawnpore, to disperse and utterly destroy all mutineers and insurgents." At this time Lady Canning wrote of him in her diary: "General Havelock is not in fashion, but all the same we believe that he will do well. No doubt he is fussy and tiresome, but his little old stiff figure looks as active and fit for use as if he were made of steel." Havelock proved himself the man for the occasion. At Fatehpur, on July 12, at Aong and Pandoobridge on the 15th, at Cawnpore on the 16th, at Unao on the 29th, at Bushertunge on the 29th and again on Aug. 5, at Boorhya on Aug. 12, and at Bithur on the 16th he defeated overwhelming forces. Twice he advanced for the relief of Lucknow, but twice prudence forbade a reckless exposure of troops wasted by battle and disease in the almost impracticable task. Reinforcements arriving at last under Outram, he crowned his successes on Sept. 25, 1857 by the capture of Lucknow. There he died on Nov. 24, 1857, of dysentery, brought on by the anxieties and fatigues connected with his victorious march and with the subsequent blockade of the British troops. He received a K.C.B. Other honours, a major-generalship and a baronetcy, he did not live to receive; they were conferred on his heir.

See J. C. Marshman, *Life of Havelock* (1860); A. Forbes, *Havelock* (English Men of Action Series, 1890); F. M. Holmes, *Four Heroes of India* (1892); G. B. Smith, *Heroes of the Nineteenth Century* (1901); L. J. Trotter, *The Bayard of India* (1903).

HAVELOK THE DANE, an Anglo-Danish romance. The hero, under the name of CUHERAN or CUARAN, was a scullion-jongleur at the court of Edelsi (Alsi) or Godric, king of Lincoln and Lindsey. At the same court was brought up Argentille or Goldborough, the orphan daughter of Adelbrict, the Danish king of Norfolk, and his wife Orwain, Edelsi's sister; and Edelsi, to humiliate his ward, married her to the scullion Cuaran. But, inspired by a vision, Cuaran and Goldborough set out for Grimsby, where Cuaran learned that Grim, his supposed father, was dead. His foster-sister, moreover, told him that his real name was Havelok, that he was the son of Gunter (or Birkabeyn), king of Denmark, and had been rescued by Grim, who though a poor fisherman was a noble in his own country, when Gunter perished by treason. The hero then wins back his own and Goldborough's kingdoms, punishing traitors and rewarding the faithful. The story exists in two French versions: as an interpolation between Geffrei Gaimar's *Brut* and his *Estorie des Engles* (c. 1150) and in the Anglo-Norman *Lai d'Havelok* (12th century). The English *Havelok* (c. 1300) is written in a Lincolnshire dialect and embodies abundant local tradition. The name of Havelok (Hablok, Abloec, Abloyc) is said to correspond in Welsh to Anlaf or Olaf. The close similarity between the Havelok saga and the story of Hamlet (Amlethus), as told by Saxo Grammaticus, was pointed out long ago by Scandinavian scholars (see *HAMLET*). Part of the Havelok legend lingers in local tradition. Havelok destroyed his

enemies in Denmark by casting down great stones upon them from the top of a tower, and Grim is said to have kicked three of the turrets from the church tower in his efforts to destroy the enemy's ships. John Weever (*Antient Funerall Monuments*, p. 749, 1631) says that Grimsby merchants were free from toll in Elsinore through the interest of Havelok, the Danish prince; and the common seal of the town of Grimsby represents Grim, with "Hablok" on his right hand and Goldborough on his left.

The unique English ms. of *Havelok* (Mss. Laud Misc. 108) in the Bodleian was edited for the Roxburghe club by Sir F. Madden in 1828. This edition contains the two French versions. There are subsequent editions by W. W. Skeat (1868) for the E. E. Text Society, by F. Holthausen (1901), and by W. W. Skeat and K. Sisam (1915); and a modern English version by Miss E. Hickey (1902). Gaimar's text and the French *lai* are edited by Sir T. D. Hardy and C. F. Martin in *Rerum Brit. med. aev. scriptores*, vol. i. (1888). See also the account of the saga by H. L. Ward (*Cat. of Romances*, i. 423-446); for the identification of Havelok with Anlaf Curan see G. Storm, *Englische Studien*, iii. 533 (1880), a reprint of an earlier article; E. K. Putnam, *The Lambeth Version of Havelok* (Baltimore, 1900).

HAVENSTEIN, RUDOLF (1857-1923), German financier, was born at Meswitz on March 10, 1857, the son of an official in the Prussian judicial department. He studied at Heidelberg and Berlin and entered the judicial service, transferring in 1890 to the Ministry of Finance. He became president of the Prussian State bank in 1900, and in 1908 succeeded Koch as president of the Reichsbank, the affairs of which he conducted during the critical war and post-war periods. He was blamed for giving excessive credits after the war and thus conducting to the deterioration of the currency. He died in Berlin on Nov. 20, 1923.

HAVERFIELD (BALGUY), EVELINA (1867-1920), English war hospital worker, daughter of the 3rd Baron Abinger, was born on Aug. 9, 1867. She married Major Haverfield, R.A., in 1887, and *en secondes nocces* General Balguy in 1899. She collected abandoned troop horses on the veldt during the Boer War and nursed them back to good condition. She was among the first London suffragists to be sentenced to imprisonment and organized a branch of the Women's Social and Political Union. She joined the Women's Emergency Corps in August 1914, founded and organized the Women's Volunteer Reserve, and was commandant-in-chief of the Women's Reserve Ambulance (Green Cross) Corps. She gave heroic service to the Serbian wounded during the war, and returned to Serbia in 1919 to establish an orphanage for Serbian children. She succumbed to pneumonia, brought on by fatigue and exposure, on March 21, 1920, at Baiyna-Bachta.

HAVERFIELD, FRANCIS JOHN (1860-1919), English historian and archaeologist, was born at Shipston-on-Stour on Nov. 8, 1860. Educated at Winchester and New college, Oxford, he became a tutor at Christ Church in 1891, and Camden professor of ancient history in 1907. Haverfield was an authority on the history and antiquities of Roman Britain, and was entrusted by Mommsen with the editing of the British section of the *Corpus Inscriptionum*. He died at Oxford on Sept. 1, 1919. Amongst his publications were *The Romanization of Roman Britain* (1905, 4th ed. 1923), *Ancient Town Planning* (1913), and many monographs on Roman history.

For a bibliography of his works see *The Journal of Roman Studies*, vol. viii.

HAVERFORD, a township of Delaware county, Pa., U.S.A., and a village of the same name, gm. N.W. of Philadelphia, served by the Pennsylvania railroad. The population of the township was 6,631 in 1920. It is a residential suburb and the seat of Haverford college, founded in 1833 by the Society of Friends. This is one of the few older colleges which have remained small. The enrolment is kept at about 250, while the endowment has grown to over \$4,000,000, permitting a faculty of unusual size in proportion to the number of students, and a total expenditure for each student of about twice the amount he pays for lodging, board and tuition. The Quaker spirit has been carefully cherished. Three times a month the college in a body attends the Friends' meeting.

HAVERFORDWEST (Welsh Hwlfordd), chief town of Pembrokeshire, South Wales, municipal borough and a county of itself with its own lord lieutenant. Pop. (1921) 5,756. Situated

at the highest navigable point on the western Cleddau where the river is also bridgeable, it is also a focus of routes from St. Davids, Fishguard, Cardigan, Narberth, Pembroke and Milford Haven. The streets are steep because the houses cluster around the castle on a hillock. The site is undoubtedly older than the Norman intrusion as the district abounds in place names of Scandinavian origin. Large numbers of Flemings were permitted by Henry I. to settle in the hundred of Roose or Rhos in the years 1106–08, 1111, 1156. The castle, though first mentioned in 1214, is believed to have been built in 1120 by Gilbert de Clare, first Earl of Pembroke, with the object of keeping an important road to Ireland open as well as of protecting the English and Flemish colonists. The church of St. Mary has an elaborate carved 15th century oak ceiling as well as many interesting memorials. To the west of the church is a curious vaulted building (perhaps late 12th century) once the record office, but now a market hall. Other churches are St. Thomas' (15th century) and St. Martin's (14th century). There are also ruins of an 11th century Augustinian priory. The old walls and fortifications of the mediaeval town have almost disappeared. The earliest charter known is one from Henry II. Further charters were presented by King John, William Marshall II., and Edward V. In 1536, under Henry VIII. Haverfordwest was declared to be a town and county of itself and was further empowered to send representative burgesses to parliament. The castle was garrisoned for the king in the Civil War but was captured by Parliament in 1644–45 and afterwards demolished. The town remained prosperous through maritime commerce during the 17th and 18th centuries, but with the rise of Milford Haven the trade of Haverfordwest declined. The town, today, relies on the marketing of agricultural produce, but still retains an importance out of proportion to its modern significance. A special feature of such towns is the large number of charities. In Haverfordwest these include John Perrot's bequest (1579) yielding about £350 annually for the improvement of the town and Tasker's charity school founded in 1684.

HAVERHILL, a market town of Suffolk, England. Pop. of urban district (1921) 4,083. It is 55 m. N.N.E. from London by the L.N.E. railway, on the Long Melford-Cambridge branch. The church of St. Mary is Perpendicular, but extensively restored. There are large manufactures of cloth, silk, matting, and a considerable agricultural and transport trade.

HAVERHILL (hāv'ril), a city of Essex county, Massachusetts, at the head of navigation on the Merrimack river, 33 m. N. of Boston. It is served by the Boston and Maine railroad. The population was 53,884 in 1920 (24.7% foreign-born white). The city has an area of 34.35 sq.m., extending for 9 m. along the N. bank of the river, and including on the opposite bank the former town of Bradford. The surface is undulating, with several detached round hills (250 to 340 ft. high), and there are five lakes within the boundaries. The public parks have an area of 259 ac. and there is a system of supervised playgrounds. Haverhill has been an important industrial centre for over two centuries. The manufacture of slippers, shoes and boots, which has long been the leading industry, was established about 1795, and the city now makes about $\frac{1}{2}$ of all the women's shoes produced in the country. The husband of Hannah Dustin (*see* below) was a brickmaker, and that industry has been carried on in the same locality ever since. The manufacture of woollen hats dates from the middle of the 18th century, and woollen mills were established in 1835. The aggregate factory output in 1925 was valued at \$55,163,457. The assessed valuation of property for 1927 was \$68,149,900. Haverhill was founded in 1640 by the Rev. John Ward, a native of Haverhill, England. The Indian name of the place was Pentucket. The site was bought from the Indians in 1642 for £3.10s., and the deed is preserved in the museum of the Historical society. The frontier settlement suffered severely from the Indians. In 1698 Hannah Dustin, with her new-born child and nurse, were kidnapped and carried north to the vicinity of Penacook, now Concord, New Hampshire. With the aid of the nurse and a captive English boy, Mrs. Dustin tomahawked and scalped ten Indians, and escaped down the river to her home. In 1708 a party of 250 French and Indians attacked the village, killing 40 of the inhabitants. There

was a destructive fire in 1873, and again in 1882, when almost the whole of the shoe district was burned. A petition from Haverhill to the House of Representatives in 1842, praying for the peaceable dissolution of the Union, was one of the most violently debated of the long series presented by John Quincy Adams in his defence of the right of petition. Haverhill was the birthplace (1807) and the home until 1836 of John Greenleaf Whittier. The Whittier homestead, now kept as a literary shrine, is the scene of his *Snow-Bound*, and his poems are full of allusions to places in the city and incidents in the lives of its people. Haverhill was incorporated as a town in 1645; as a city in 1869. Bradford, settled in 1649 and annexed to Haverhill in 1897, is the seat of Bradford academy (1803), one of the oldest schools for girls in the country. In 1909 the city adopted a commission form of government.

HAVERSACK or HAVRESACK, the bag in which horsemen carried the oats for their horses (through the French from Ger. *Habersack*, an oat-sack, a nose-bag, *Hafer* or *Haver*, oats). In Scotland and the north of England *haver*, meaning oats, is still used, as haver-meal or haver-bread. Haversack is now used for the strong bag made of linen or canvas, in which soldiers, sportsmen or travellers, carry their personal belongings, or more usually the provisions for the day.

HAVERSTRAW, a village of Rockland county, New York, on the W. bank of the Hudson river, 35 m. above New York city. It is served by the Erie and the West Shore railways. The population in 1925 was 5,925. The village has a beautiful location at the base of High Tor (832 ft.), on a wide bay of the river. It has a silk mill and dye plant, and extensive manufactures of brick and brickmaking machinery. A mile distant are large calico print works employing 2,000 workers. The region was settled by the Dutch, probably as early as 1648. Near the village is the house where Benedict Arnold and Major André met before daylight on Sept. 22, 1780, to plan for the betrayal of West Point. In 1826 a short-lived Owenite community (dissolved within five months) was established near West Haverstraw. Haverstraw was incorporated under the name of Warren in 1854, and re-incorporated as Haverstraw in 1873.

HAVET, JULIEN (PIERRE EUGENE) (1853–1893), French historian, was born at Vitry-sur-Seine, the second son of Ernest Havet. His valedictory thesis at the Ecole des Chartes, *Série chronologique des gardiens et seigneurs des Iles Normandes* (1876), was a definitive work and but slightly affected by later research. In 1878 he followed his thesis by a study called *Les Cours royales dans les Iles Normandes*. His first work on the Merovingian institutions was *Du sens du mot "romain" dans les lois franques* (1876), a critical study on a theory of Fustel de Coulanges (*q.v.*). In this he showed that the status of the *homo Romanus* of the barbarian laws was inferior to that of the German freeman; that the Gallo-Romans had been subjected by the Germans to a state of servitude; and, consequently, that the Germans had conquered the Gallo-Romans. He died prematurely at St. Cloud on Aug. 19, 1893.

The two posthumous volumes, *Questions mérovingiennes* and *Opuscules inédits* (1896), contain besides important papers on diplomatic and on Carolingian and Merovingian history, a large number of short monographs ranging over a great variety of subjects. *Mélanges Havet* (1895) contains a bibliography of his works compiled by his friend Henri Omont.

HAVILDAR, the Hindustani name of the sepoy non-commissioned officer in the British native army of India, who ranks below a *jemadar* but above a *naik*, and which corresponds to the rank of sergeant in the British Service. The *havildar* wears 3 chevrons as his badge of rank. The name is a corruption of the Persian *hawālādār* or *hawāldār*, *i.e.*, one holding a position of trust, such as a steward, agent or subordinate revenue officer, and in this sense it has many applications in India and Persia. As a military rank it was introduced into the native army of India in the 18th century.

HAVILLAND, GEOFFREY DE (1885–), British aeronautical engineer, was born at Haslemere, and educated at St. Edward's school, Oxford, and at the Crystal Palace school of engineers. He learnt to fly on his own ground at Haslemere, and made his first ascent in June 1910, in an aeroplane designed by

himself. He took up aeroplane designing commercially, and produced the "Airco" and "De H" machines, becoming director of the De Havilland Aircraft Company.

HAVRE, LE, the second seaport of France and capital of an arrondissement in the department of Seine-Inférieure, on the estuary of the Seine, 143 m. W.N.W. of Paris and 55 m. W. of Rouen. Pop. (1926) 155,129. Until 1516 Havre was only a fishing village possessing a chapel dedicated to Notre-Dame de Grâce, to which it owes the name, Havre (harbour) de Grâce, given to it by Francis I. when he began the construction of its harbour. The town in 1562 was delivered over to the keeping of Queen Elizabeth by Louis I., prince de Condé, leader of the Huguenots, but the English were expelled in 1563 by Charles IX. and his mother, Catherine de Medici, in person. Defences and harbour-works were continued by Richelieu and completed by Vauban. The English bombarded it in 1694, 1759, 1794 and 1795. It was a port of considerable importance as early as 1572, and despatched vessels to the whale and cod-fishing at Spitsbergen and Newfoundland. In 1672 it became the entrepôt of the French East India company, and afterwards of the Senegal and Guinea companies. Napoleon I. raised it to a war harbour of the first rank, and under Napoleon III. works begun by Louis XVI. were completed. During the World War Britain and America used Havre as a base and point of landing for troops and stores. Also after the fall of Antwerp and Ostend the Belgian Government was transferred here and housed in the Hôtel des Régales at St. Adresse to the northwest. After the armistice it formed one of the American embarkation points. Trade has again reached its highest pre-war point.

The greater part of the town stands on the level strip of ground but on the north rises an eminence, la Côte the richer quarter. The central point of the town is the Place de l'hôtel de ville in which are the public gardens. The church of Notre-Dame, dating from the 16th and 17th centuries is a mixture of late Gothic and Renaissance styles of architecture but the tower is older. The carved oak organ case was the gift of Cardinal Richelieu. The chief buildings of Havre, including the hôtel de ville, the law courts, and the exchange, are all of modern erection. The museum contains a collection of antiquities and paintings. Havre is the seat of a sub-prefect, and a tribunal of first instance, a tribunal of commerce, a board of trade arbitrators, a tribunal of maritime commerce, a chamber of commerce and a branch of the Bank of France. There are 14 basins (the oldest of which dates back to 1669) with more than 8 m. of quays. Work has been continued on the 1909 programme of port improvements, which includes a large graving dock and wharfage in tidal basin, a floating dock and pontoons, a basin for large oil tankers and reservoirs in the outer harbour, and a wharf and mole for goods storage in the north part of the port. A petroleum pipe line to Paris has been built. The chief docks are the Bassin Bellot and the Bassin de l'Eure. In the latter the mail-steamers of the Compagnie Générale Transatlantique are berthed; and the Tancarville canal, by which river-boats unable to attempt the estuary of the Seine can make the port direct, enters the harbour by this basin. The port, which is an important point of emigration, has regular steam-communication with New York and with many of the other chief ports of Europe, North, South and Central America, the West Indies and Africa. Havre is the great French port for cotton and coffee and also imports copper and other metals, wool, rum, foreign wines, oil seeds and dyewoods. Its industries are rope making, timber for building, wire drawing, machinery making, flour-milling, oils, dye extracting from woods, spinning and weaving, toy and chemical works.

HAVRE, a city of northern Montana, U.S.A., 35m. from the Canadian border, on the Milk river and Federal highway 2; a division point on the Great Northern railway, and the county seat of Hill county. The population was 1,033 in 1900; 5,429 in 1920; and was estimated locally at over 7,000 in 1928. It has railroad shops, a creamery, a flour mill, and a cold storage plant and is an important shipping point for wheat, live stock and poultry. Irrigation works are under construction in the vicinity. The city was settled about 1880 and was incorporated in 1896.

HAVRE DE GRACE, a city of Harford county, Md., U.S.A., 36m. N.E. of Baltimore, at the head of Chesapeake Bay and the mouth of the Susquehanna river. It is served by the Baltimore and Ohio and the Pennsylvania railways, and by steam-boat lines. The population was 4,377 in 1920 (18% negroes). It has several manufacturing industries and a considerable trade in coal, lumber and fish. There is a fine race-track here, of national repute, and at Aberdeen, 5m. S.E., are the U.S. artillery-proving grounds.

HAWAII (hah-wī'i; native hah-vah'ē-ē), **HAWAIIAN** or **SANDWICH ISLANDS**, capital Honolulu (*q.v.*), geographically a chain of islands near the centre of the north Pacific ocean, 1,578 m. from E.S.E. to W.N.W., between 18° 55' and 28° 25' N. and 154° 48' and 178° 25' W. Politically, as a Territory of the United States, it consists of the islands ceded by the Republic of Hawaii to the United States in 1898 and made a Territory by Congress in 1900, and hence excludes the small coral island, Midway, which was acquired by the United States in 1859 and has been used since 1902 as a cable station, and includes two small uninhabited coral islands not in the chain, Johnston (or Cornwallis) and Palmyra.

Hawaii, comprising both volcanic and coral islands built up from depths of 15,000 to 18,000 ft., is the northernmost of the central Pacific island groups. It has the largest area (6,412 sq.m.), and greatest altitude (13,825 ft.). It is also the most isolated of important land areas. The nearest important groups to the south are Samoa, 2,263, and Tahiti, 2,390 nautical miles. To the north, Unalaska in the Aleutian islands is 2,106, and to the west, Guam is 3,337 miles. The distances in nautical miles from Honolulu to principal ports of the Pacific are: San Francisco, 2,091; Los Angeles, 2,228; Seattle, 2,409; Sitka, 2,395; Yokohama, 3,394; Sydney, 4,420; Panama, 4,685; Manila, 4,838; Hongkong, 4,936; Valparaiso, 5,918. Cape Horn is 6,488 miles. The large, high, inhabited islands, Hawaii (4,016 sq.m.), Maui (728), Molokai (261), Lanai (139), Kahoolawe (44), Oahu (598), Kauai (547) and Nihoa (73), together with their nearby small uninhabited islands, form the east-south-east fourth or about 375 m. of the chain, extending to 22° 14' N. and 160° 15' W. The islands of the remainder of the chain are so small that their total area is only 6 sq.m., and yet they afford a rich field for the naturalist. Those in the west half of this part of the chain are coral (mostly sand) islands; those in the other half, forming a transition link with the large inhabited islands, are lava-rock. The islands of the entire chain apparently were formed beginning at the westerly and finishing at the easterly end, where there are still active volcanoes.

Westerly Islands.—The small westerly group are remains of larger islands which have mostly eroded. The lava-rock ones rest on more or less extensive banks lying at small depths, and the coral ones are sand islands or islets on the rims of large atolls. Those of lava-rock are Nihoa or Bird (895 ft. high), Necker (276), French Frigates shoal (a rock 120 ft. high and 16 sand islets) and Gardiner (170); the coral ones, 10–40 ft. high, are Laysan, Lisiansky, Pearl and Hermes reef (12 islets), Midway (Sand island, a cable station and Eastern island), and Ocean or Cure (Green island, and two islets). In addition there are Frost shoal, Brooks shoal, Maro reef, Dowsett reef and Gambia bank, which are just awash or do not reach the surface. None are inhabited except for the cable station at Midway. For a time Laysan was occupied for its guano until the deposits became exhausted. Necker has stone platforms and enclosures, perhaps temples, of unknown origin; stone images and dishes found there are in Honolulu museum. The Hawaiians anciently visited Nihoa and Necker to obtain materials for their famous feather work as well as for fish. There is little vegetation except grasses and shrubs. The waters abound in fish and turtles, and, especially at Pearl and Hermes reef, a species of hair seal found nowhere else. These islands are most noted, however, for their bird life, and in 1909 all of them except Midway were created by the National Government into the Hawaiian Islands Bird Reservation, to protect them from Japanese poachers who, for the feathers, killed some 300,000 birds in one season. Collectively, they form the largest and most

numerous bird colony in the world. One naturalist estimated at over ten millions the number of birds, resident and migratory, in a single year at Laysan alone, an island $1\frac{1}{4}$ m. by 1 m., with a lagoon a mile long in the centre. These are of many varieties, some not found elsewhere, including frigate, man-o'-war, tropic, mutton and miller birds, the Laysan canary, finch, duck and honey-eater, terns, curlews, turnstones, stilts, plover, shovellers,

MAP SHOWING CENTRAL GEOGRAPHICAL RELATION OF HAWAII TO FOUR CONTINENTS

boobies, tatlars, petrels and shearwaters that burrow like rabbits, rails that have only rudimentary wings and cannot fly, and, most numerous, albatrosses that indulge much in curious dances, two by two. Many are remarkably unafraid of man.

Hawaii.—The island of Hawaii, which contains two-thirds of the area of the group, is roughly triangular in shape, with sides of 90, 75 and 60 m.; it consists of five volcanic mountains about 20 m. apart, connected by saddles 3,000–7,000 ft. high, formed by overlapping lava flows. Being the newest island, and still in the making by volcanic action, little of its 297 m. of coast is bordered with coral reefs, and there has been little erosion except along the 60 m. of the north-east coast from the principal harbour, Hilo, to the north end of the island, the windward side of the older mountains, where copious rains and ocean waves and currents have created valleys and cliffs increasing northward in depth and height and culminating in the Waipio and Waimano valleys, several thousand feet deep, receding from coastal cliffs 1,500 ft. high. Throughout the rest of the island there is not a stream except at times of unusual rain—partly because of the porosity of the rocks and soils, and, on the leeward side, partly because of insufficiency of rain.

The Kohala mountain or range (5,505 ft.), the oldest, its windward side deeply eroded, its top a water sponge, its leeward side dry, with the higher slopes covered with cinder cones, forms the north angle of the island. Next, south-easterly, is Mauna Kea ("White Mountain," so-called from the snow on its summit). There are glacial markings on its upper windward slopes. At 13,000 ft. there is a small lake, which often freezes over, and nearby are extensive quarries of fine-grained, compact greyish stone, of which the Hawaiians of old made their best adzes and other implements. The crater has disappeared, blown up in an explosive eruption, or covered by reddish cinder cones, which in great numbers dot the summit and upper slopes. This is not only the highest mountain of the group but the highest island mountain in the world (13,825 feet). In a real sense it is also the highest of all mountains in the world, for, although many others are higher above sea-level, this starts from a great plain 18,000 ft. below

sea-level and is built up from that as a single mountain, rising within a distance of 50 m., to a height of nearly 32,000 feet.

South-westerly from Mauna Kea is Hualalai (8,269 ft.), whose summit, like that of Mauna Kea, has no great crater and is covered with cinder cones, but, unlike Mauna Kea, has many small pit craters. Its only flow in historic times was in 1801. Further south is Mauna Loa, "Long Mountain," twin of and 150 ft. lower than Mauna Kea. Except for the cinder cones of the latter it would be higher. It is an immense lava dome, not only the largest volcano, but the largest mountain in the world in cubic content; it discharges more lava than any other volcano. On the summit is an elongated pit crater, Mokuaweweoe (3.7 sq.m.), with vertical walls 500 to 600 ft. high, from which radiate black and brown lava flows of bygone ages. While at times, especially preceding eruptions, the summit crater is exceedingly active, no flow has originated there in historic times. All historic flows, except submarine, have burst from the sides at elevations of 7,000 to 13,000 ft., usually on two lines running north-east and south-west respectively from the summit. The principal flows of the last century were in 1832–43–51–52–55–59 (33 m. long, 1 m. wide in places), 1868, 1877 (submarine), 1880–81–87–99; 20th century 1907–16–19 and 1926.

Lastly and easternmost, is Kilauea, with the largest and most spectacular of all active craters, an oval pit 4.14 sq.m. in area, with walls now 500 ft. high—1,000 ft. a century ago. It is hardly a distinct mountain, for, although an independent volcano and older than Mauna Loa, it is merely a hole in the side of the latter at an elevation of 4,000 ft.; it is reached by motor in an hour, over 30 m. of concrete road through tropical forests from Hilo. Except for occasional flows over the floor of the main pit, visible activity has, for several decades, been confined to an oval inner pit, Halemaumau, 3,000 by 3,500 ft., and 1,300 ft. deep in 1928. Operating in cycles, the lava rises until it overflows and breaks through some subterranean passage and drains out, only to begin the cycle again. During the 19th century and the early years of the 20th the only flows of size outside the crater, and some distance from it, were those of 1823–40–68 and 1920–21, but small quantities of lava have erupted nearer in 1832–68, 1922 and 1923. Just before the last drop-out, in 1924, the lake of boiling molten lava covered about 50 ac., and when the lava fills the present enlarged caldera it will cover about 190 acres.

Only two explosive eruptions have occurred in historic times, those of Kilauea in 1790 and 1924, the earlier of which destroyed a division of a Hawaiian army. Earthquakes have been numerous and tidal waves occasional on the east coast of Hawaii island, but have done little damage, except in 1868, when, at the time of the lava flow of that year, a landslide 1 by 3 m., the so-called "mud flow," killed 31 persons; a tidal wave swept away several small villages, killing 46 persons, many houses were levelled, great cracks opened and the coast subsided some feet. All historic flows of Mauna Loa and Kilauea have been in regions of few or no habitations. That of 1826 covered the small village of Hoo-pulua without loss of life. The lavas are of two kinds, *pahoehoe*, of smooth but wrinkled, shiny surface, and *aa*, exceedingly broken and jagged. Since 1911 a volcanic observatory has been maintained at Kilauea, and in 1916 the National Government created the Hawaii National park consisting of the Kilauea and Mauna Loa sections (116 and 28 sq.m.) on Hawaii, and the Haleakala section (26 sq.m.) on Maui, to which was added in 1927 a strip (72 sq.m.) connecting the first two sections. In the Kilauea section, visited by 60,000 persons annually, besides the active volcano, there is much of interest, such as numerous other pit craters, sulphur banks, pumice beds, lava tubes, tree molds, lava trees, lava spatters in trees, stalactites, Pele's hair (Pele being the Hawaiian goddess of volcanoes), tropical forests and birds and sulphur-steam baths.

Maui, Molokai, Lanai, Kahoolawe and Molokini (the last uninhabited), probably once a single island, are now separated by channels only 6 to 10 m. wide and 250 to 600 ft. deep. They are separated from Hawaii by a channel 26 m. wide and 6,192 ft. deep, and from Oahu by one 23 m. wide and 2,244 ft. deep.

Maui, shaped like the head and bust of a woman, consists of

two mountains (East and West Maui) connected by a low isthmus 6 m. wide. One of these mountains, Haleakala ("House of the Sun," 10,032 ft.), has on its summit the largest of all extinct craters, 20 m. around and 2,720 ft. deep; on whose floor of 19 sq.m. are 16 reddish cinder cones 400 to 900 ft. high. The view from the summit is the grandest in the Territory. The windward side, a succession of gorges, rich in waterfalls and verdure, supplies the water for the irrigation of the arid isthmus. It is traversed by a wonderfully scenic drive. The other mountain, whose highest peak is Puu Kukui (5,788 ft.), being much older, is marked by deep radiating canyons such as the Iao or Wailuku valley (4,000 ft. deep), which is of marvellous beauty.

Molokai likewise consists of two mountains, Mauna Loa (11,382 ft.) at the west end and Kamakou (4,958 ft.) at the east end, connected by a saddle 400 ft. high, both cut off by erosion on the windward side, so that the island is narrow and of fairly even width, 40 by 7 miles. The windward side, one of the most scenic coasts of the group, is a precipice, 500 to 4,000 ft. high, sheer from the ocean, the highest part of which is deeply indented by magnificent valleys, and on a low peninsula, projecting from the base of which, near its centre, is the famous leper settlement.

Lanai (3,480 ft.) and **Kahoolawe** (1,472 ft.) are single mountains, with cliffs on their southerly coasts exposed to the ocean, their northerly coasts being protected by Maui and Molokai. Cattle, sheep and goats have destroyed their forests except on the summit of Lanai. Recently, a pineapple company has acquired Lanai, constructed a harbour on the south coast and a model city in the centre of an extensive interior plateau, which it is reducing to cultivation. Molokini is a small crescent-shaped, barren, rocky island, 160 ft. high, the ruin of a volcano, between East Maui and Kahoolawe.

Oahu was once two immense volcanoes; erosion has made of it two parallel mountain ranges, one, Koolau (Konahuanui, 3,105 ft.) twice as long as the other and older, Waianae (Kaala, 4,030 ft.), connected by a saddle 800-1,200 ft. high, is roughly square in shape except for the extension of the Koolau range at the east, which is the longest in the group; both ranges are among the most rugged. Their outer sides are precipices with marginal lower country, 0-7 m. wide, at their bases, and are most scenic with lofty, fluted faces and broken sky-lines. There are many small, recent tufa, ash and lava cone craters, mostly coastal, especially in and about Honolulu. There are also elevated coral formations and evidences of earlier and greater subsidences. This island, though third in size and fifth in height, is important agriculturally. It contains the capital and trade centre on the lee coast of the east end and the land-locked Pearl harbour (10 sq.m.) at the crotch of the ranges (see HONOLULU). The picturesque sites of this island are easily accessible; the most noted panoramic view being that of the windward side, which bursts suddenly on one upon arrival at the Pali (precipice), the only traversable pass (1,200 ft.), 6 m. up a beautiful valley back of Honolulu.

Kauai, separated from Oahu by a channel 63 m. wide and 11,232 ft. deep, is roughly circular in form, about 25 m. across, and consists mainly of one mountain (Waialeale, 5,250 ft.), with marginal low lands except on the north-west. It is the oldest, most disintegrated, and most verdant of the larger islands, abounding in rivers and waterfalls. Its chief scenic attractions are the Grand canyon of the Waimea (3,000 ft. deep) in the south-west, comparable in colours and forms to the Grand canyon of the Colorado; the spacious Hanalei valley in the north; and the Napali coast of precipices, 4,000 ft. high, on the north-west. This, with its canyons, fluted ridges, pinnacles, caves and waterfalls, is a most remarkable scenic region, though difficult of access.

Niihau, separated from Kauai by a channel 15 m. wide and 3,300 ft. deep, is a small island, 17 by 6 m., of which the east central third is a tableland 1,300 ft. high, with cliffs on the ocean side, and the remainder lowland of coral origin. The entire island is a sheep ranch privately owned. Lehua and Kaula, uninhabited, are crescent-shaped remains of tufa cones, respectively $\frac{1}{2}$ m. N. and 23 m. S.W. of Niihau. Both are rookeries.

Climate.—The chief determinants are the prevailing north-east trade winds from over cool ocean currents and the remarkable heights and contours of the land areas. The result is a climate cooler than elsewhere in the same latitude, equable temperatures, abundant sunshine and absence of tropical storms. Mauna Loa and Haleakala form such barriers to the trade winds that their leeward slopes have regular land and sea breezes. At times, especially in winter, a "kona," or southerly wind, brings mugginess and heavy rain. The windward slopes are cooler than the leeward, and the temperature falls about 1° F for each 300 ft. of altitude. There is no distinctly rainy or dry season, but usually more rain falls in winter than in summer. There is wide variation in temperature, rainfall and wind for neighbouring localities. In 1905-26 the temperature varied on Hawaii island from 98° (lee shore) to 25° (at 6,685 ft.), and on Maui the annual rainfall varied from 2.46 in. (at 90 ft. on the isthmus) to 562 in. (at 5,000 ft. only 8½ m. distant), said to be the lowest and highest of all official records. The summit of Kauai has, perhaps, the greatest average rainfall in the world. The greatest in 24 hours was 31.95 in. on windward Hawaii. At the Bureau office in Honolulu, on leeward Oahu, the average annual rainfall was 28.60 in. and the mean annual temperature 74.6°, with a maximum of 88°, a minimum of 56°, a mean maximum of 79.4° and a mean minimum of 69.5°. Four miles distant, at 1,028 ft., the average rainfall was 155.02 inches. Usually there is snow on Mauna Kea and Mauna Loa and sometimes on Haleakala.

Flora.—The isolation of Hawaii, its division into islands, the barriers of deep canyons and high precipices, and the wide variations in rainfall, temperature, wind, barometric pressure and geologic age of different localities, have evolved a flora that not only is exceptionally extensive for the area, but ranks first in the world in percentage of endemic genera and species. The number of species is over two-thirds that of New Zealand, which has 16 times the area. The percentage of endemics is 83, as compared with 34 in Samoa, 35 in Tahiti, 53 in Fiji and 75 in New Zealand. There are about 900 species of flowering plants (over 300 being trees), 140 ferns (from the moss-like *Trichomanes parvulum*, the size of a finger nail, to the stately tree-fern, *Cibotium menziesii*, 35 ft. high), and also many hundred mosses, lichens, fungi and algae. The species are most numerous and best defined on the older islands; some are extremely localized. One endemic violet is confined to an area of a few square yards. In a 56 ac. oasis of rich soil surrounded by lava flows in the National park, there are 40 species of trees, several unique; one, when discovered, consisted of only a single specimen. From this a new genus was named, *Hibiscadelphus*, of which two other species have since been discovered, one of them a single specimen on Maui. Some species of trees vary from 1 ft. to 40 ft. and others from 30 to 100 in height according to altitude. Several species of violets have woody stems 6 ft. high. Most developed are the *Lobelioidae*, of which there are over 100 species; these range from dwarf forms to palm-like giants 40 ft. high. This tribe is more developed only in South America. There are some 60 species of composites, a score of which are arborescent, such as the silversword (*Argyroxiphium sandwicense*). Hawaii, however, is poor in native palms, of which there is only one genus with ten species, and in orchids, of which there are only three insignificant species. There are but few trailing forest vines, though the luxuriant and brilliant-flowered *ieie* (*Freycinetia arnottii*) and the glossy, fragrant *maile* (*Alyxia olivaeformis*), favourite for leis (wreaths), are common. The forests are tropical and only a few trees shed their leaves seasonally.

Six botanical regions or zones are commonly treated more or less separately: strand, lowland, lower forest, middle forest, mountain bog and upper forest, with subdivisions of dry and wet, windward and leeward, etc., each having in large measure its distinct flora, but with considerable overlapping. Above 11,000 ft. there is practically no vegetation.

Hundreds of species have been introduced into the islands since their discovery by Europeans and about 25 were introduced anciently by the Hawaiians. Among the ancient introductions are the coco-nut, breadfruit; *ohia ai* or mountain apple (*Jambosa*

HONOLULU AND THE HAWAIIAN ISLANDS

1. Surf riding at Waikiki Beach, Honolulu
2. Nuuanu Pali, a valley pass six miles from Honolulu, which affords a famous panoramic view. It is the only traversable pass on the windward side of the Island of Oahu
3. Mauna Kea and Mauna Loa, twin mountains on the Island of Hawaii, as seen from Hilo Bay. Mauna Kea (White Mountain), so called from the snow on its summit, reaches an altitude of 13,825 feet, the highest island mountain in the world. Mauna Loa (Long Mountain), 150 feet lower than Mauna Kea, has an immense lava dome; it is not only the largest volcano, but the largest mountain in the world in cubic content
4. View of Honolulu, capital of the Hawaiian Islands, and of its harbour, from the crater of the Punchbowl, an extinct volcano a mile behind the city
5. Panoramic view from the Nuuanu Pali (see fig. 2)

malaccensis); taro (*Colocassia antiquorum*, roots used for making a paste, *poi*, the principal food of the Hawaiians); sweet-potato; yam; banana; pia or arrowroot (*Tacca pinnatifida*); sugar cane; gourd; *awa* and *ti* (*Piper methysticum* and *Cordyline terminalis*), roots used for making drinks, and leaves of *ti*, for wrappers, plates, etc.; olona (*Touchardia latifolia*, yielding exceedingly strong and durable fibre for fish nets, etc.); *wauke* (*Broussonetia papyrifera*), fibre used for making *kapa* or paper cloth; *kukui* or candle-nut (*Aleurites moluccana*), useful for candles, oil, dyes, paint, gum, food and medicine; *milo* (*Thespesia populnea*) and *kou* (*Cordia subcordata*), now almost extinct, and *kamani* (*Callophyllum inophyllum*), all three yielding beautiful wood valued for making calabashes and other dishes; and *hau* (*Paritium tiliaceum*), useful for making outriggers and rope and training over arbours for shade, *noni* (*Morinda citrifolia*), useful for dyes and perhaps ginger. Among the more common later introductions are the avocado or alligator pear, mango, pineapple, orange and other citrus fruits, papaya, guava, coffee, grape, fig, *poha* or cape gooseberry, litchi, mulberry, tamarind, date, passion fruits, eugenias, cherimoya, custard apple and the Queensland nut.

Fauna.—Isolation and wide variations in local conditions have had much the same effect, though in lesser degree, on the fauna as on the flora, resulting in a high percentage of endemics and extreme localization. There is only one certainly indigenous land mammal, a small bat. Dogs, hogs, and perhaps rats and mice, were introduced anciently by the Hawaiians, and many domestic mammals have been brought in since Cook's discovery; some very early, as goats and English pigs by Cook in 1778; cattle and sheep by Vancouver in 1793, and horses by Cleveland in 1803. Spotted deer (*Cervus axis*) were introduced in 1867 and the mongoose in 1883, to destroy rats.

There were about 125 species of birds, resident and migrant, of which, perhaps, a score are now extinct. On the inhabited islands the native birds are disappointingly few, as their habitats are mostly in the forests and on the heights. A striking example of bird evolution is found in the song-bird family (*Drepanididae*) with 60 species, all peculiar to Hawaii. Most prized for feather work were the yellow feathers of the now-extinct *mamo* (*Drepanis pacifica*) and nearly-extinct *oo* (*Moho nobilis*); the vermilion, of the *iwai* (*Vestiaria coccinea*); and the crimson, of the *apapani* (*Himatione sanguinea*). Very common are the brown *elepao* (*Chasiempis sandwichensis*); the green-and-yellow *amakihi* (*Chlorodrepanis* spp.); and the *ou* (*Psittirostra psittacea*), the best Hawaiian songster. A wild goose, *nene* (*Bernicia sandwichensis*), confines itself to dry areas. The birds most commonly seen on the lower and more open areas are exotics. Chickens were anciently introduced by the natives, and the later introductions include, besides various domestic fowls, the skylark, Chinese thrush, mynah, turtle dove, pigeon, linnet, blue-cheeked parrot, rice bird, English sparrow, pheasant, quail and California partridge.

The only native land reptiles are seven species of small skinks and geckos, commonly called lizards. There are no snakes, and the frogs and toads are introductions. Although there are several thousand species of indigenous insects, mostly endemic, they are not troublesome or destructive. The noxious forms are mostly introductions, such as the sugar-cane leaf-hopper and borer, rice-borer, Mediterranean fruit fly, melon fly, Japanese beetle, horn fly, cutworms, army worms, termites, fleas and mosquitoes. Perhaps no animal group has contributed more light on the subject of evolution than the 500 species of land and fresh-water shells of Hawaii, especially the beautiful tree shells (*Achatinellidae*). The exceptionally rich marine animal life includes more than 650 species of fish, many of which are fantastic in shape and colour. Among introduced fishes are trout, carp, black bass, catfish, goldfish and top minnows.

Industries.—Sandalwood was Hawaii's first important commercial product. The industry (1800-40) originated through fur-traders, and was at its height during 1810-25. The wood was shipped to China, and the king and chiefs found the business so lucrative that they compelled most of the available population to get the wood from the forests, so that it was soon exhausted. But before that whaling (1820-80) began. The vessels usually

called twice a year for rest, repairs, supplies, storage or transhipment of oil and whalebone and engagement of Hawaiians as seamen. The average annual calls during 1840-60, when the industry was at its height, averaged about 400. Whaling was also local. The discovery of petroleum (1859) and the destruction of whaling vessels in the Civil War and by the northern ice pack in 1871 lessened its importance. Hawaiians were excellent seamen; in 1846 about a fifth (3,000) of the young men of 15-30 were so engaged.

The chief product of the islands has long been sugar. Small quantities were produced from 1802 to 1835, when the industry really began, and yet the output had increased to only 13,036 short tons by 1876, when there was great impetus from the reciprocity treaty with the United States. It increased to 229,414 tons by 1898, the year of annexation, 517,090 in 1910 and 811,333 in 1927. For 25 years acreage and number of employees have remained fairly constant, but better methods have greatly increased the output. The sugar and pineapple industries, especially have profited from scientific methods as applied through the sugar planters', pineapple planters' and U.S.A. experiment stations, University of Hawaii and Territorial Bureau of Agriculture and Forestry. The yield per acre averages $7\frac{1}{2}$ tons of sugar on irrigated and 5 tons on unirrigated land, with a maximum of 18 tons. The cane, however, requires from 14 to 30 months to grow and only a little over half the area (120,000 ac.), is harvested each year. Two or three crops at different stages grow at the same time. About half the area is irrigated—by conduits from mountain streams and pumping from artesian and surface wells. The irrigation system of one plantation cost nearly \$6,000,000. Before a field is harvested it is set on fire to burn off the leaves. Conveyance to the mills is by railway, flumes and overhead trolley. The centrifugal drying process for sugar was invented in Hawaii in 1851. All but one plantation ships sugar raw, mostly to their co-operative refinery in California. Corporations own the mills and raise most of the cane. Of the 45,000 or so unskilled employees about 95% work by contract and are provided with living quarters, gardens, medical attendance and other advantages without cost.

The pineapple industry, a growth of this century, is second only to sugar in importance. The output of all companies has increased from 1,893 cases in 1903, to 8,879,252 (213,102,048

GRAPH SHOWING THE PRODUCTION OF SUGAR IN HAWAII, 1871-1928

cans) in 1927. The area cultivated is about 50,000 acres. This industry, unlike sugar, had to create its market.

The live stock, coffee and rice industries have successively occupied second place. There are numerous ranches and dairies, many with thoroughbred stock—cattle, sheep, horses, hogs and poultry. The coffee industry, one of the oldest, is taking on new life. The coffee is of superior quality, known as "Kona" from the district on western Hawaii where most of it is raised. Rice is a waning industry. The banana industry is steady, though not large. Other industries which are still small or have had their day, but some of which have possibilities, are silk, cotton, tobacco,

GRAPH SHOWING THE RACIAL COMPOSITION OF HAWAII, 1900 AND 1920

rubber, vanilla, sisal, potato, wheat, flour, macadamia nut, etc. While Hawaii exports and imports a larger percentage of what it produces and consumes than most countries, there is nevertheless much subsistence farming, and several industries, such as live stock, fish, fruit and vegetable, figure largely in local trade. Little lumber is produced. Practically the only mineral products are building stone, lime and salt. Much has been done since 1850, and especially since 1895, to promote homesteading of public lands, not altogether successfully; but since 1920 a new policy has been pursued, with greater success, under which permanent improvements are made in advance by the Government, settlers are selected with reference to their qualifications, long-time loans at low rates are made and instruction is given by specialists.

Although Hawaii is essentially an agricultural country, the principal industries are such as require much manufacturing directly, as in sugar, pineapple, rice, coffee and fish mills and canneries, and indirectly, as in iron, fertilizer and can works of large size. The principal iron works has long held a leading place in manufacturing sugar machinery. Manufactures of poi, biscuits, macaroni, starch, soft drinks, confectionery, shoes, clothing, furniture, musical instruments, concrete pipes and tiles, lime, boats, etc., are on a small scale. There have been but two serious strikes on sugar plantations (1909 and 1920) and there is little unionism. There is a workman's compensation law. Railway, telephone, telegraph and wireless utilities are under the Interstate Commerce Commission and other utilities under the Territorial Public Utilities Commission. The tourist business, as an industry, is next to sugar and pineapples. Tourists increased from 8,000 in 1921 to 17,500 in 1927. The great prosperity of Hawaii for half a century is reflected in the resources (\$108,052,385 on Dec. 31, 1927) of its 12 banks and 11 trust companies. On June 30, 1927, there were 111,861 savings accounts, with deposits of \$27,102,219. There were 1,071 Hawaiian corporations, and 194 foreign corporations.

Commerce.—In 1927 imports were \$88,837,477, and exports \$111,504,035 (\$25,138,247 and \$46,486,412 in 1920). Trade is mostly with the mainland of the United States (\$79,665,662 of imports and \$109,236,321 of exports in 1927), while \$9,171,815 of imports and \$2,267,714 of exports were with foreign countries. The exports comprised sugar, \$69,827,821; fruits and nuts, mostly canned pineapples, \$34,934,087; coffee, \$1,779,829; sugar machinery, \$512,877; hides, \$170,034; and molasses, tallow, wool, canned fish, bananas, rice, honey, etc. Imports from the mainland of the United States comprise a wide range of articles, while those from foreign countries are largely food stuffs from Japan, China, New Zealand and Australia, fertilizers from Chile and Germany, and jute bags from India.

Communications.—At Honolulu, besides model concrete

wharves and sheds, there are dry-docks, electric freight-handling apparatus, automatic coal-handling plants, and oil tanks connecting with the wharves by pipe lines. From 1910 to 1927 trans-oceanic steamers, exclusive of naval vessels, army transports and coal-bunker vessels, increased from 570 to 1,089, sailing vessels decreased from 257 to 10, the combined tonnage increased from \$2,666,780 to \$8,228,331 in value, and passengers from about 90,000 to about 300,000, including through passengers. Thirteen steamers engage exclusively in interisland traffic. There are many airports, 360 m. of seven railways, hundreds of miles of concrete and macadam roads, and over 35,000 motor vehicles. The larger islands have telephone systems. Honolulu has an electric street railway. Hawaii was the first country to establish wireless for commercial purposes. Besides a cable there are four powerful wireless plants for trans-Pacific communication and smaller plants for communication between the islands and with ships at sea.

Population and Immigration.—Since the discovery (1778), the population has changed from extreme homogeneity to extreme heterogeneity, due to decrease of Hawaiians during the first century and immigration of others during the last half century. The discoverer estimated the Hawaiians at 400,000 but probably they did not exceed 300,000. Their decrease, due to many causes, has been rapid, but latterly at a diminishing rate. They now seem destined to disappear more through intermarriage with other races than through excess of deaths. The part-Hawaiians are increasing more rapidly than the pure Hawaiians are decreasing. The birth-rate of the former and death-rate of the latter are the greatest among all the races. In 1823 the missionaries estimated the Hawaiians at 142,050. The first census (1832) showed a total population of 130,313, including the few foreigners. That of 1872 showed low ebb in the total, 56,897 (51,531 Hawaiians and part-Hawaiians). That of 1878, just after the Reciprocity Treaty with the United States began to stimulate immigration, showed 57,985, divided 47,508 and 10,477. That of 1900, when Hawaii became a Territory, showed 154,001, divided 37,656 (low ebb of Hawaiians and part-Hawaiians) and 116,345.

The last census (1920) showed 255,912, divided 41,750 and 214,162. On June 30, 1927, the total was estimated at 333,420: Hawaiian, 20,931; Caucasian-Hawaiian, 15,208; Asiatic-Hawaiian, 9,437; American and northern European, 34,750; Portuguese, 28,417; Spanish, 1,774; Porto Rican, 6,572; Filipino, 52,124; Chinese 25,198; Japanese, 132,242; Korean, 6,214; others 553. These include many crosses. The distribution was: City of Honolulu, 106,600; remainder of city and county of Honolulu, 64,650; city of Hilo, 12,394; remainder of county of Hawaii, 66,160; county of Maui, 47,060; county of Kauai, 35,970; county of Kalawao, 586. Immigration of large numbers of Chinese, Japanese

and Korean adult males formerly produced highly abnormal ratios of aliens to citizens, males to females, singles to married and adults to children, but latterly, due to cessation of such immigration, deaths and departures, marriage, immigration of wives and births within the Territory, there has been a rapid tendency toward normality, retarded somewhat by similar immigration of Filipinos.

In 1927, 217,618 (65.27%) were U.S.A. citizens and 115,802 were not (including Filipino immigrants who are neither citizens nor aliens but owe allegiance to the United States). Native-born constituted 41.1% in 1900, 51.1% in 1910 and 53.3% (or, omitting the recently-arrived Filipinos, 57.2%) in 1920. Males fell from 69.1% in 1900 to 64.1% in 1910, and to 59.1% in 1920, notwithstanding the large influx of Filipino males. Increase of population except of Americans and Filipinos, is now mainly through births. Departures of most others exceed arrivals. In 1927 the birth-rate was 37.16 and the death-rate 11.87 per 1,000. The birth-rate was highest among Asiatic-Hawaiians (74.26), next among Caucasian-Hawaiians (59.74), and lowest among Americans and northern Europeans (11.65). Japanese births were 46.8% of the total and the rate per 1,000 was 43.88. The death rate was highest among Hawaiians (31.11), next among Caucasian-Hawaiians (16.06), Filipinos (15.29) and Asiatic-Hawaiians (14.52), and lowest among Americans and northern Europeans (6.85%), followed closely by Spanish (8.41%), Japanese (8.85%) and Koreans (9.76%). There is a growing tendency toward intermarriage among all races, although least among Japanese and Koreans. It is increasingly difficult to classify by races because of mingling; racial antagonisms are absent.

Experiments in Immigration.—On the "cognate race" plan, Polynesians from the South Sea islands were introduced in 1859, 1865, 1868-71, 1874 and 1878-85, 2,454 in all, but they were disappointments, both as labourers and prospective citizens, and most of them were returned to their homes. On the "desirable citizen" plan, Caucasians other than Latins were introduced, as Americans in 1870 and 1898, Norwegians in 1881, Germans in 1882-85 and 1897, Galicians in 1898, Russians in 1909-14 and

from Portugal. Simultaneously 7,695 Spanish were brought from Malaga, but most of these have left, and, although many Portuguese also have left, those in the Territory had increased to 28,417 by 1927. In 1898, 255 Italians were introduced and in 1900-01 about 5,000 Porto Ricans. Most of the latter remained and, contrary to first indications, the majority have developed well and increased to 6,572. About 100 negroes and their families (1901) and about 500 Hindus (1908-11) were introduced, most of whom soon left. Aside from the Portuguese,—the Chinese, Japanese, Koreans and Filipinos have constituted the bulk of the labour immigrants. The Chinese came first (1,632 in 1852-67); then, opposition having developed, 148 Japanese were introduced in 1868, but, the Japanese Government objecting, no more were brought in and the Chinese continued to come (2,819 in 1868-77) when, in 1878, the immigration of Portuguese began, but not to the exclusion of the Chinese, who continued to come unassisted in large numbers (20,791 in 1878-85). The Chinese became so numerous that restrictive measures were applied in 1883 and attention was again turned to Japan. Chinese immigration almost ceased, the total for 1886-99 having been only 6,129, of whom 5,241 came in 1895-97, just before the Federal Chinese exclusion laws were extended to Hawaii upon annexation. Japanese came in large numbers, at first assisted and then unassisted, 65,034 during 1885-99, of whom 19,908 came the last year, fearing that such immigration also might be inhibited. Many went from Hawaii to the mainland, the arrivals having been 96,092 and the departures, to the mainland and Japan, 92,221 during 1900-15, but after the "Gentlemen's Agreement" of 1907 between the United States and Japan the arrivals were largely women, which resulted in rapid increase through births. Opposition on the mainland led to Japanese exclusion in 1924. The Chinese immigrant population resident in the islands decreased from 25,762 in 1900 to 21,674 in 1910, but the total of both immigrant and Hawaiian-born Chinese increased, through excess of births over deaths and departures, to 23,507 in 1910 and 25,178 in 1927. The Japanese increased from 61,115 in 1900 to 79,675 in 1910, 109,274 in 1920 and 132,242 in 1927. Koreans to the number of 7,859 came in 1903-05, but there were only 4,533 in 1910 and 4,950 in 1920; since then they have increased through births to 6,214 in 1927.

Finally, largely because of the enactment of Federal laws prohibiting assisted immigration from foreign countries, the sugar companies turned to Filipinos as the only available source, beginning in 1906, and, although many go to the mainland, the number has grown to 2,361 in 1910, 21,031 in 1920 and 52,124 in 1927, and they have become the largest racial element on the sugar plantations. The Filipinos, like the Porto Ricans, contrary to adverse predictions and some early disappointments, have responded well to better food and health conditions and training in ways of industry and thrift. Under the Federal laws the oriental immigrants cannot be naturalized because they belong to the excluded races, and the Latin immigrants usually cannot qualify because of illiteracy, but the Hawaiian-born children of all are citizens by birth. These for the most part display ability and character, and, particularly among the orientals, both the parents and the children are ambitious for the latter's education. While the racial diversity, and especially the large number of Japanese, furnish Hawaii's greatest problems, they appear to be in process of solution.

GOVERNMENT AND EDUCATION

The Hawaiian Islands are a Territory, an integral part, not a possession, of the United States, governed under an Organic Act, effective from June 14, 1900. The Federal officers are a delegate to Congress, elected for two years, who may introduce bills and debate but not vote, two judges of a Federal district court and a U.S.A. attorney and marshal, appointed for six years by the president with the consent of the Federal Senate, and various officials of the Treasury, Post-office, Agriculture, Commerce and Interior departments. The Territorial legislature, which meets biennially, consists of a senate of 15 members elected, seven or eight at each biennial election, for four years, and a house of representatives of 30 members elected for two years. The president, with the consent of the Federal Senate, appoints for four

GRAPH SHOWING THE RELATIVE PROPORTION OF MALES AND FEMALES IN HAWAII AT EACH CENSUS FROM 1898 TO 1920

Poles in 1914, about 4,450 in all, but most of them soon outgrew the status of unskilled labourers or left the islands.

Attention was then directed chiefly to the Latins, particularly the Portuguese. Consequent upon the pressing demand for labour occasioned by the Reciprocity Treaty and after investigation of the relative merits of immigrants from many countries, 10,798 Portuguese were brought from Madeira and the Azores in 1878-90 and 337 in 1899. They proved to be industrious, thrifty and law-abiding. They brought their families and most of them remained and multiplied. In 1906-13, 5,196 more were introduced, many

years the governor, the secretary, who acts as governor in the absence or disability of the latter, the chief justice and two associate justices of the supreme court and the eight judges of the five circuit courts. The governor, with the consent of the Territorial senate, appoints for four years, and with like consent may remove, the attorney-general, treasurer, auditor, commissioner of public lands, superintendent of public works, superintendent of public instruction, surveyor, high sheriff, and, for various terms, all members of boards and commissions, among which are those of health, harbours, public instruction, public utilities, agriculture and forestry, fish and game, farm loan, pension, university regents, registration of voters and inspectors of election.

Hawaii, having previously been an independent sovereignty, is the most highly organized Territory created by Congress and is the only one to which has been given the administration and revenue of its public lands. The chief justice appoints for two years one or more district magistrates for each of the 27 district courts. Certain designated circuit judges serve also as judges of the land court (Torrens), the court of domestic relations and the juvenile courts. Equity and law are kept distinct but with simplified procedures. Appeals may be taken from the Federal district court and, when a Federal question or a value in excess of \$5,000 is involved, from the Territorial supreme court to the Federal circuit court of appeals of the ninth circuit. Local governments were first created in 1905. These are (1928) the city and county of Honolulu, comprising the island of Oahu and all small islands not included in any other county and hence extending 1,350 m. W. and 1,100 m. S. of Honolulu, the city and county seat; county of Hawaii, comprising the island of that name, county seat at Hilo; county of Maui, comprising the islands of Maui, Molokai (except the leper settlement), Lanai and Kahoolawe, county seat at Wailuku; county of Kauai, comprising the islands of Kauai and Niihau, county seat at Lihue; county of Kalawao, comprising the leper settlement. Each includes also the small islands within 3 m. of the shores of the larger ones. Each, except Kalawao, which is only an inchoate county under the board of health, has a board of supervisors, sheriff, clerk, auditor, attorney and treasurer elected for two years. Honolulu has also a mayor. Territorial and local officers and the Federal judges, attorney and marshal must, in general, be citizens of the United States and have resided in the Territory one to three years next preceding election or appointment.

The qualifications of voters are citizenship, residence of a year in the Territory and three months in the district, age of 21 years, ability to speak, read and write the English or Hawaiian language, and registration, which is permanent except that if one fails to vote at any election his name is struck out and he must reregister in order to vote. Absent seamen may vote, but those in the army or navy may not. Except Kauai supervisors and the Kalawao sheriff, all Territorial and local elective officers are elected at large or from multi-member districts. Direct primaries have been in operation since 1913 and woman suffrage since 1920. The political parties are the Republican and Democratic, the former preponderating. Citizenship by birth and naturalization are governed by the Federal Constitution and laws. At the last general election (1926) the registered voters numbered 40,569, as follows: Hawaiian and part-Hawaiian, 17,763; Caucasian, 16,808 (10,793 Anglo-Saxon and 6,115 Latin, mostly Portuguese); Oriental, 5,998 (3,092 Japanese, 2,096 Chinese). Over 85% of those who registered voted.

Finance.—On June 30, 1927, the Territory had a cash balance of \$1,613,679.74, with no floating debt. On April 10, 1928, the bonded debts were: Of the Territory, \$27,010,000 (4 and 4½%), of which \$10,791,871.55 was incurred for the local governments, which reimburse the Territory in interest and sinking funds; of the city and county of Honolulu, \$7,330,000 (5 and 5½%); and in the same city and county, \$2,863,767.80 of district improvement bonds (5 and 6%) payable solely by the property benefited. Most bonds sell at a premium. All such debts have been incurred since 1910 for public improvements, for which also much current revenue has been expended. For the year ended June 30, 1927, the revenue was \$17,519,921.65; of which \$8,138,-

292.60 went to the Territory and \$8,381,629.05 to the local governments (as compared with \$2,621,758 and \$1,394,695 in 1910), derived from property, income, inheritance, personal, vehicle and insurance taxes, licence fees, water and sewer rates, fines and costs, sales and leases of public land, etc. The assessed value of property was \$414,064,603 as compared with \$150,268,467 in 1910. The Territory has also paid in taxes to the Federal Government an average of about \$10,700,000 a year during the last decade—ranking each year above 13–17 States. In 1925 the legislature provided for a Territorial budget system, a pension system for Territorial employees, and a uniform accounting system for the Territorial and local governments.

Education.—A dozen years after the arrival of the first missionaries in 1820 there were 900 schools with 53,000 pupils (40% of the population, mostly adults); a dozen years later about 80% were literate. In 1824 the regent and chiefs prescribed schools and compulsory attendance. In 1831 and 1834 there were founded two higher institutions for training teachers and religious assistants, which were also largely manual and industrial training schools, said to be the first of the kind established in what is now the United States. It was his knowledge of these industrial schools that led a missionary's son, Gen. Samuel C. Armstrong, to establish Hampton institute in Virginia. His father was minister of public instruction 1847–60. In the '30s and '40s pupils came from Spanish California, Kamchatka and other Pacific islands to attend an English-taught school opened in Honolulu in 1833.

The educational system includes all grades from kindergarten to university, as well as a normal school and schools for the physically defective, feeble-minded and juvenile delinquents and evening classes. Much attention is given to agricultural, trade and industrial vocational work (including part-time schools), home economics and medical, dental and nutritional needs. The university (about 1,000 students) maintains an aquarium and marine biological laboratory, conducts extension work and renders important service in industrial experimental and research work. Prominent among private schools are Oahu college (1,000 students) founded in 1841 (where most of the Anglo-Saxons are prepared for mainland universities), the Kamehameha schools (for Hawaiians) largely industrial, St. Louis college (Catholic, for all races), and the Mid-Pacific institute (for all races). School attendance is compulsory for children from six to 14 years of age. English has been the medium of instruction since long before annexation to the United States.

The public school system is under the Territorial Government, buildings and other physical equipment under the local governments. The cost is over \$5,000,000 a year. On Dec. 31, 1927, there were (exclusive of the university) 186 public schools with 2,286 teachers and 66,577 pupils, and 47 private schools with 440 teachers and 9,497 pupils. The pupils comprised 74,119 American born and 1,955 foreign born—by race, 3,971 Hawaiians, 9,080 part-Hawaiians, 7,633 Portuguese, 337 Spanish, 1,137 Porto Ricans, 4,499 other Caucasians, chiefly Americans, 7,304 Chinese, 36,692 Japanese, 1,568 Koreans, 3,043 Filipinos and 810 others. In some schools 40–50 races and interracial mixtures are represented. In addition there are many racial language schools, chiefly Japanese, which hold short sessions before or after the public school hours. There is an excellent Territorial public library at Honolulu, with branches or stations throughout the Territory, and public libraries at the other county seats, all of which co-operate closely with the schools.

Charities.—The department of public health is second in importance only to that of education. Physicians are employed or subsidized for the benefit of all, however indigent or remote from population centres. The principal institution is the Molokai leper settlement, with its auxiliary hospital in Honolulu. Formerly emphasis was laid on isolation, but since 1909 it has been placed on treatment, and the number of lepers has greatly decreased. At one time there were over 1,200 lepers in these institutions and many at large; in 1927 there were 654 confined and few at large. There are many charitable and welfare institutions throughout the islands.

HISTORY

History Before Discovery.—Polynesia was probably the last habitable area to be occupied by man. The Polynesians, although of similar features, language, customs, religion and traditions, are not a pure race. They are supposed to be mainly of Aryan origin, with infusions of other bloods, and to have come from Asia by way of the Malay peninsula and Java, and thence from island to island by various routes in their migrations eastward, northward and southward, and to have reached Hawaii, probably from Samoa, about A.D. 500. The next five centuries were for the Hawaiians a period of seclusion and peace. Then, in the 11th to 13th centuries, a time of activity throughout Polynesia, intercourse was resumed with Tahiti, Samoa and other islands over 2,000 m. to the south by huge sailing canoes. During this period many chiefs, who intermarried with Hawaiian reigning families, and priests came to Hawaii, both classes became powerful and the severity of tabus and frequency of human sacrifices increased. Then followed another long period of isolation, the last centuries of which were full of wars and rebellions—the result of pressure of population, rapacity of the nobility and dynastic ambitions and jealousies.

Feudalism grew up much as it did in mediaeval Europe and from much the same causes. The unit of land, the *ahupuaa*, usually extended from the shore to the mountain top, with rights in the adjoining sea waters, so that the occupants had the means of supplying all their wants—the sea for fish, the littoral for coconuts, the valley for taro, their principal food, the lower slopes for sweet potatoes, yams and bananas and the mountain for wood. The next subdivision was the *ili*, either subservient to the *ahupuaa* or independent. Within these were small areas, *kuleanas*, occupied by the common people, who also had certain rights of fishery, water and mountain products. Besides open sea fisheries, there were stone-walled fish-ponds, some now a thousand years old, built semi-circularly from the shore. Taro was raised in terraces flooded by conduits from streams. Elaborate systems of water rights were evolved. A conqueror or a successor king often redistributed the lands.

The Hawaiians were a brown race, with straight or wavy black hair, attractive features, large and of fine physique, like the New Zealand Maoris, whose dialect resembled theirs. The chiefs were physically superior to the common people, often weighing 300 to 500 pounds. Their mentality also was better. Being of pure blood, they inbred to advantage. Polygamy and polyandry were practised, especially among the chiefs. Rank descended mainly through the mother. The language is soft and musical, vowels and liquids predominating. There are only 12 letters, the vowels and h, k, l, m, n, p and w, l and r and k and t being interchangeable, and, as each syllable consists of only a vowel or a consonant followed by a vowel, there are only 40 syllables to make the more than 20,000 words. The Hawaiians were fond of oratory, poetry, history, story-telling, chants, riddles, conundrums and proverbs, and paid much attention to the proper use and pronunciation of words. Without writing, knowledge of all sorts was preserved and taught to successive generations by persons specially trained for the purpose. Without metals, pottery or beasts of burden, implements, weapons and utensils were made of stone, wood, shell, teeth and bone, and great skill was displayed in arts and industries. The feather-work (capas, robes, helmets, *leis*, *kahilis*) has not been excelled. Houses were of wood frames and thatched, with stone floors covered with mats. Food was cooked in holes in the ground, *imus*, by means of hot stones, but many foods, including fish, were often eaten raw. Many of the best foods were tabu to women. Men usually wore only a *malu* or girdle and women a skirt of *kapa* or paper cloth or leaves or fibre, though both sometimes wore mantles thrown over the shoulders. Canoes were outrigger or double, sometimes 100 ft. long. They have hardly been surpassed as sailors, fishermen or swimmers. They were skilful navigators, knowing stars, winds and currents. Their year began on Nov. 20 and consisted of 12 lunar months with occasionally an intercalary month. They had remarkable knowledge of animals and plants and were great warriors, using spears, javelins, clubs and slings,

but no shields or bows, the latter being small and used only for shooting rats and mice for sport.

They excelled in athletics, in which there were frequent contests, even between champions of different islands, in surf-boarding on the crests of waves, swimming, wrestling, boxing, spear-throwing (at each other), coasting down permanently prepared courses standing on narrow sleds, bowling, foot-racing, etc. Surfing has now become a favourite sport for others as well as Hawaiians. They gambled much and made narcotic and fermented drinks of the *awa* and *ti* roots, but not distilled liquours. They were fond of music, vocal and instrumental, and had percussion, string and wind instruments, including a nose flute but no mouth flute. The *ukulele* is of Portuguese origin, developed and popularized by the Hawaiians. Their dances were largely the notorious *hula* of many varieties, the better forms of which have latterly become popular with others. They loved flowers, which they wore much in *leis* or wreaths about necks and hats. This has become customary with the whites, especially on arrivals and departures of steamers and on May day. They tattooed little. Their proverbially courteous, generous, hospitable spirit has affected the remainder of the population.

There were four principal gods, *Kane*, *Kanaloa*, *Ku* and *Lono*, and innumerable lesser gods and tutelar deities. Animals, plants, places, professions, families, all objects and forces had their gods or spirits. Temples of stone and idols of wood abounded and hardly anything was undertaken without religious ceremonies. On important occasions there were human sacrifices. There was a vague belief in a future state. Priests and sorcerers were potent. There were "cities of refuge" to which one might flee and be safe. Cannibalism was unknown but infanticide prevalent. The political and religious systems were closely interwoven.

During the last period before the discovery, although there were occasional bright intervals under highminded kings, and notwithstanding that there was so much that was praiseworthy, in general, the nobility and priesthood became more and more aristocratic and tyrannical, the common people more and more degraded; destruction of life was frightful; property was insecure; there was little encouragement for industry; the laws, chief among which were the intricate and oppressive tabus, bore heavily upon the masses, especially the women, and their administration became largely a matter of arbitrariness and favouritism.

History After Discovery.—A vessel of the Spaniard Alvarado de Saavadra's squadron, fitted out by Cortez, sailing from Mexico to the Moluccas, was wrecked at Kaei, Hawaii, in 1527. Conceded until recently, it is now disputed, that the Spaniard Juan Gaetano discovered Hawaii in 1555, and Capt. James Cook is considered the discoverer of Hawaii. Cook first landed at Waimea, Kauai, on Jan. 18, 1778. The natives thought him the god Lono. On his return the next year, he was killed, after a period of friendly relations with the natives, on Feb. 14, 1779, in an affray at Kaawaloa, Hawaii, where a monument to him now stands.

Then followed a period of contact with pre-missionary whites (1778-1820), a period of political consolidation and religious disintegration. Kamehameha I., the most striking figure in Hawaiian history, came to the throne of one of the then four kingdoms in 1782, and, equipping himself better than his foes with vessels, firearms and aids, foreign and native, succeeded by 1795 in conquering all the islands except Kauai and Niihau, and in securing the latter by cession in 1810. Having effected consolidation, he organized the Government, checked oppression encouraged industry and suppressed crime, until, as it was said, "the old, men and women, and little children could sleep safely in the highways." He thwarted Russian designs upon the islands (1815-16) and eliminated Spanish pirates (1818). It was in this period that the sandal-wood trade developed. In 1804 an epidemic, probably cholera, destroyed much of the population.

Benign foreign influences were exerted by such voyagers as Vancouver (1792-94), Cleveland (1803) and Kotzebue (1816), and such residents as John Young and Isaac Davis, captured (1790) boatswain and mate, and Don Francisco de Paula Marin, immigrant (in 1791) from Andalusia, who introduced useful

plants and animals and inculcated higher ideals. But baleful foreign influences were exerted by numerous Botany bay convicts, pirates, buccaneers, beach-combers, adventurers and others, who introduced the art of distillation, fire arms, venereal diseases and vices of all kinds.

Kamehameha treated foreigners well but combated their vices. Indulging a little at first, he later abstained from the use of liquors and ordered the destruction of distilleries. Having unsuccessfully sought to obtain teachers of Christianity, he adhered to the Hawaiian religion and enforced strict observance of it, but with lessening severity. The last human sacrifices were in 1807. However, foreign influences undermined faith in the old religious systems, and shortly after his death (May 8, 1819), these were abolished (about Nov. 1, 1819) under the leadership of his favourite queen, Kaahumanu, and his queen of highest rank, Keopuolani—not, however, without a bloody battle (Dec. 20, 1819) between the progressives and conservatives. Thus, union under a single Government, the establishment of peace and order, and the dissolution of the old politico-religious bonds, prepared the way for new social forces.

The Third Period of Hawaiian History began with the arrival of the first company of missionaries from New England on March 31, 1820. Fourteen other companies followed during the next 35 years, in all over 150 men and women—ministers, teachers, physicians, printers, farmers and business men. They introduced the church, the school and the press. The Hawaiians were most eager to learn. By Jan. 7, 1822, the missionaries had learned the language, reduced it to writing and begun printing the first text-book. Two months later the first printed law was issued. By 1840 50 books had been printed. In 1834 two Hawaiian newspapers were published. An English newspaper, founded in 1843, is still published. The first press on the Pacific coast was imported from Hawaii into Oregon in 1839. The New Testament was completed in 1832, the Old in 1839, the dictionary in 1865. Of great assistance was William Ellis, English missionary in Tahiti, who visited Hawaii in 1822. While Christianity soon came to be regarded as the national religion, and churches were well attended everywhere, little interest was taken in it as a personal matter until 1829, when there were 185 church members, of whom 117 joined that year.

Interest culminated in the "Great Revival" of a decade later, which added a fifth of the population. The first convert (1823) was Keopuolani, head queen of Kamehameha, mother of the next two kings and highest chief by blood in the nation. Indeed the chiefs, especially the females, led in embracing and supporting the new religion and learning. Kaahumanu, Kamehameha's favourite queen, was converted in 1825 and was thereafter known as the "New Kaahumanu," as strong for good as she had theretofore been haughty and cruel, and of the ten who joined the church in 1826, nine were chiefs, including Kalanimoku, known as the "Iron Cable." Kaahumanu and Kalanimoku were the strongest characters in the nation.

Women in Power.—Kamehameha I., recognizing the weaknesses of his son, Liliho (Kamehameha II.), had appointed Kaahumanu to be his *kuhina nui*, or premier, with power almost equal to that of the king. She acted as regent when the king and queen visited England in 1824, and, they having died there of the measles, she continued as regent until her death (1832), the new king, Kamehameha III., being then an infant. Kalanimoku had been prime minister and treasurer to Kamehameha I. and continued such under Kaahumanu until his death in 1827. Kaahumanu was succeeded as *kuhina nui* by Kinau, daughter of Kamehameha I. and mother of Kamehameha IV. and Kamehameha V., until her death in 1839, and then by Kekaulohi, mother of King Lunalilo, until her death in 1845. These noble women, Keopuolani, Kaahumanu, Kinau and Kekaulohi and others, like Kapiolani, whose courageous defiance of *Pele* (1824) was sung by Tennyson, and Bernice Pauahi Bishop, who twice refused the crown and gave (1884) all the Kamehameha lands to found schools for her race, would have done credit to any nation.

The first score or so of years after the arrival of the mis-

sionaries was a crucial period, not so much because of the inherent difficulties of civilizing and christianizing a barbarous and pagan race as because of the opposition of whites. This opposition came not only from the beach-combers and grog-shop keepers, but, more dangerously, from British, French and American consuls and naval officers. They opposed the laws against licentiousness and drunkenness, slandered the missionaries, made unjust claims against the Government, insisted that they were not subject to Hawaiian laws, attacked with arms the homes of missionaries and chiefs, aimed at the overthrow of the Government; the British consul claimed that the islands had become British territory.

Democratic Sovereigns.—This period was not, however, without bright spots in helpful foreign influences both from residents and from such visitors as Lord Byron of the British navy, cousin of the poet, who brought back the bodies of the king and queen in 1825, and Capt. Jones (1826) and Capt. Finch (1829) of the American navy, the former of whom negotiated the first treaty entered into by Hawaii. Whaling had become active in 1820 and the sugar industry in 1835. There was trouble over Catholic priests who came in 1827; they were banished in 1831, on the ground, among others, that they were reviving idolatry which had been abolished in 1819, but returned in 1836-37. Meanwhile, due to increasing complications with foreigners, growth in liberal and humane sentiments on the part of the chiefs and in realization of their natural rights by the common people, a conviction arose of the need of a better defined and more advanced form of Government as a condition of peace, progress and independence.

Hence, after vain attempts to secure from New England teachers of the science of government, the missionaries were induced to detach one of their number, W. Richards. He rendered notable service to the Government as did two other missionaries, G. P. Judd and R. Armstrong, similarly detached later. After hearing a course of lectures on government (1839) delivered to the king, chiefs and leading commoners, the king promulgated the *Declaration of Rights*, called Hawaii's *magna charta*, June 7, 1839, the *Edict of Toleration*, June 17, 1839, and the first Constitution, Oct. 8, 1840. The first compilation of laws was published in 1842. The Catholics began their cathedral in 1840, and ever since, through churches and schools, have done much good work. Contrary to the usual course of history, in Hawaii democratization evolved from the top downward rather than from the bottom upward.

But troubles with foreigners were not at an end. French naval officers in 1839, 1842, 1849 and 1851 made unjust demands, the first and third times accompanied by force. A British naval officer took possession in 1843 and held it until the flag was restored by higher authority. After the ceremonies, the king, addressing his people on the means of preserving independence, used the expression "*Ua mau ke ea o ka aina i ka pono*" ("The life of the land is perpetuated by righteousness"), which has since been Hawaii's official motto. Diplomatic missions secured recognition of independence from the United States in 1842 and England and France in 1843.

Further troubles with foreigners, and especially the outrageous French demands of 1849 and 1851, led to other diplomatic missions, and in the latter year a secret proclamation putting the islands under the protection of the United States. The French, having learned this, retracted and the United States declined the protectorate, but, as a result of further troubles and dangers, within and without, including threatened filibustering from California, and the "manifest destiny" sentiment awakened in the United States by the acquisition of the Oregon Territory and California, negotiations were opened in 1854 for annexation to the United States but were terminated by the death of the king. The troublesome foreign representatives were removed and fairer treaties entered into. Mormon missionaries first came in 1850, and that church now has a large membership and a magnificent temple and is doing good work.

New Codes.—Encouragement of immigration began in 1852 and has continued ever since. A small-pox epidemic in 1853

TOWN AND COUNTRY SCENES IN THE HAWAIIAN ISLANDS

1. Fort Street, near Ford Street, a principal thoroughfare of Honolulu, capital of the Hawaiian Islands. It is macadamized with crushed lava. The business houses, from two to six storeys in height, are of brick or stone. Service by trolley car covers the entire district including the famous suburb of Waikiki
2. Women selling *leis* in Honolulu. These flower garlands are offered especially on steamer days being purchased to deck incoming and outgoing travelers. Most of the women are wearing *holokus*, the mother Hubbard gown adopted under the influence of the early missionaries
3. A scene in Moanalua Gardens at Moanalua (Two waters), Honolulu, one of the many parks throughout the city and its suburbs
4. Hawaiian grass hut, a type of dwelling almost entirely replaced by frame houses. It consists of a wooden frame with steep pitched roof covered with closely woven layers of grass, sometimes a foot thick, sloping downward to shed the rain. The doorway is usually the only opening
5. Grass house in Honolulu on the estate of Queen Emma, wife of Kamehameha IV., king of Hawaii 1854-63
6. Making poi, the favourite Hawaiian dish, from the root of the taro plant. The taro root is a vegetable resembling the sweet potato in appearance. After having been cooked in ground ovens, it is mashed with a stone pestle, kneaded into a paste and allowed to ferment slightly. It is now made chiefly in factories by machinery

HAWAII UNDER CULTIVATION AND VIEWS OF HALEMAUMAU CRATER

1. Rice fields on Kauai, showing the Bay of Nawiliwili. Formerly second in importance among the island's industries, rice-growing now takes fifth place and very little is exported. It is entirely grown by the Chinese, and a submerged cultivation is generally employed.
2. Pineapple fields. The growing of pineapples for canning and export was first successfully attempted in 1901 by a company holding a 12-acre plantation; today there are about 50,000 acres under cultivation.
3. A banana plantation near Honolulu in the midst of rice fields. Although originally introduced by the Hawaiians, the banana of modern cultivation is usually a foreign variety, the Chinese banana being one of the most common. It is exported in small quantities.
4. Close view of a pineapple field. The plant yields two crops, the first being harvested eighteen or twenty months after planting.
5. A section of Halemaumau, the inner pit of Kilauea, photographed at night by the glow of its own fire. The pit, which is in the centre of Kilauea, the largest continuously active volcano in the world, was 1,300 feet deep in 1928 and about 190 acres in area.
6. Halemaumau in eruption as seen from the brink of the crater. Although the surrounding mountain side is covered with solidified lava from early eruptions, there have been few eruptions with serious results, since the lava, upon reaching the edge of the crater, usually forces a subterranean passage through which it drains off.

numbered its victims in thousands. Meanwhile, after the adoption of the crude Constitution of 1840, every effort was made to organize and perfect the Government. An able lawyer, John Ricord, was appointed attorney-general in 1844 and made a famous report to the legislature of 1845, as a result of which he was requested to draft comprehensive organic acts, which were enacted in 1846-47. W. L. Lee was appointed chief justice in 1846. He was chief drafter of the penal code of 1850, the more modern Constitution of 1852 and chief compiler of the civil code of 1859. Action was taken in 1845 and subsequent years by which the old feudal tenures were changed to allodial, and the interests of Government, Crown, chiefs and common people were severed and all claims adjudicated by a board of which Lee was chairman. R. C. Wyllie, a Scot, was minister of foreign affairs 1845-65. For able and untiring service, Lee, Wyllie and Ricord are among the outstanding personages in Hawaiian history. A tower of strength was Kekuanaoa (father of Kamehameha IV. and V.), governor and judge of Oahu. The long and fruitful reign of the liberal-minded Kamehameha III. ended on Dec. 15, 1854. Hawaii had become a civilized and christianized country with constitutional Government, highly creditable legislative, executive and judicial branches, personal and property rights secure, allodial tenures, modern industries, the respect of other nations and independence assured.

The next two kings, high-minded, educated and travelled, Kamehameha IV. (1854-63) and V. (1863-72), feeling that the Government had become democratized too rapidly and that American interests were becoming too preponderant, were slightly reactionary and pro-British. The former and his consort, Queen Emma, are remembered for their founding of the Queen's hospital (1860) and the inauguration (1862) of the Episcopal Church, which, especially since annexation, has prospered. The American Board, which had sponsored the missionaries, deeming Hawaii qualified to graduate (the first nation to do so) from the field of Christian missions, withdrew in 1863 and transferred its work to the Hawaiian Board. Kamehameha V., after calling and dismissing a Constitutional Convention, himself promulgated a new Constitution (1864), which changed that of 1852 less than had been feared.

With his death ended the beneficent Kamehameha dynasty, and after the brief reign (1873-74) of the liberal, popular, pro-American Lunalilo, elected against Kalakaua, came the decidedly reactionary reign (1874-91) of the latter, elected as pro-American against Queen Emma as pro-British. The principal forces for good, the chiefs and missionaries, had largely died off. At first Kalakaua ruled fairly well and was largely instrumental in bringing about the Reciprocity treaty with the United States (1876), which produced far-reaching results. Efforts had been made from time to time since 1848 to effect such a treaty, partly for the economic benefits and partly as an alternative to annexation. The treaty was terminable after seven years on one year's notice, and agitation having arisen in the United States for such termination, an extension for seven years and until one year's notice was obtained in 1887 but only by giving the United States the exclusive right to enter Pearl harbour and maintain a naval coaling and repair station there—a right which was not exercised.

Reaction and Annexation.—There was ever-increasing endeavour by the king to restore the ancient order with its heathen customs and ideas of absolutism and Divine right, accompanied by extravagance, corruption, personal interference in politics and fomentation of race feeling, until the second generation of missionaries and their associates, including many patriotic Hawaiians, finding it impossible to stem the tide by ordinary means, rose in peaceful revolution, but with ample force in the background, and compelled the king to promulgate (1887) a new Constitution providing for responsible ministerial government and other guarantees. The struggle continued, however, not only until the end of that reign (1891), during which there was an armed insurrection (1889) by the reactionaries, but even more hotly during the following reign of the king's sister, Liliuokalani. She had some superior qualities as a poet and musical composer and was interested in welfare work; however, it was deemed necessary to de-

pose her (Jan. 17, 1893) and set up a Provisional Government. Annexation to the United States was to be sought.

This failed for the time being and a republic, with probably the most advanced Constitution ever adopted, and Sanford B. Dole, a missionary's son, as president, was established on July 4, 1894. It continued, disturbed only by an unsuccessful insurrection in 1895, until annexation was accepted, largely because its desirability was emphasized by the Spanish war, by the Joint Resolution of Congress of July 7, 1898. The transfer of sovereignty took place on Aug. 12, 1898, and the Territorial Government was established by Congressional Act of April 30, 1900, effective on June 14, 1900. There has since been uninterrupted prosperity and progress.

The governors of the Territory have been S. B. Dole, 1900-03; G. R. Carter, 1904-07; W. F. Frear, 1907-13; L. E. Pinkham, 1913-18; C. J. McCarthy, 1918-21; W. R. Farrington, 1921.

(W. F. Fr.)

HAWARDEN (pronounced Harden, Welsh *Penarlŷg*), a town of Flintshire, N. Wales, 6 m. W. of Chester, connected by a branch with the L.M.S.R. Pop. (parish, 1921) 8,016. There is an early encampment on Truman's hill west of St. Deiniol's church, an early English building restored in 1857 and 1878. Hawarden castle—built in 1752, added to and altered in 1814—stands in a fine wooded park near the mediaeval castle of the same name. The latter suffered in Welsh raids and at the hands of the Parliamentarians in the 17th century. The modern house passed to W. E. Gladstone. The Grammar school dates from 1606. St. Deiniol's Hostel, founded to house Mr. Gladstone's library, is much used by students.

HAWAWIR, an Arabized tribe of Berber origin dwelling in the Bayuda desert, Sudan, owning herds of oxen, sheep and camels. See H. A. MacMichael, *History of the Arabs of the Sudan* (1922).

HAWAZNIA: see BAKKARA.

Haweis, Hugh Reginald (1838-1901), English preacher and writer, was born at Egham, Surrey, on April 3, 1838. On leaving Trinity College, Cambridge, he travelled in Italy and served under Garibaldi in 1860. On his return to England he was ordained and held various preferments. A lively and very fashionable preacher, he was much interested in music, and wrote books on violins and church bells, besides contributing an article to the 9th edition of the *Encyclopædia Britannica* on bell-ringing. He died on Jan. 29, 1901.

Hawes, Stephen (fl. 1502-1521), English poet, was born, if his own statement of his age may be trusted, about 1474. He was educated at Oxford, and travelled in England, Scotland and France. He became groom of the chamber to Henry VII. as early as 1502. Hawes could repeat by heart the works of most of the English poets, especially the poems of John Lydgate, whom he called his master. He was still living in 1521. His capital work is *The Passetyme of Pleasure, or the History of Graunde Amour and la Bel Pucel, containing the knowledge of the Seven Sciences and the Course of Man's Life in this Worlde*, printed by Wynkyn de Worde, 1509, but finished three years earlier. The poem is a long allegory in seven-lined stanzas of man's life in this world. It is divided into sections after the manner of the *Morte Arthur* and borrows the machinery of romance. Its main motive is the education of the knight, *Graunde Amour*, based, according to W. J. Courthope (*Hist. of Eng. Poetry*, vol. i. 382), on the *Marriage of Mercury and Philology*, by Martianus Capella, and the details of the description prove Hawes to have been well acquainted with mediaeval systems of philosophy. This long poem, dull as it is, was widely read and esteemed, and certainly exercised an influence on the genius of Spenser.

The *Pastime of Pleasure* was edited by T. Wright for the Percy Society in 1845. The remaining works of Hawes are all of them bibliographical rarities. *The Conversyon of Swerers* (1509) and *A Joyfull Medytacyon to all Englonde*, a coronation poem (1509), was edited by David Laing for the Abbotsford Club (1865). *A Compendyous Story . . . called the Example of Vertu* (pr. 1512) and the *Comfort of Lovers* (not dated) complete the list of his extant work. See also G. Saintsbury, *The Flourishing of Romance and the Rise of Allegory* (1897); the same writer's *Hist. of English Prosody* (vol. i., 1906); and an article by W. Murison in the *Cambridge History of English Literature* (vol. ii., 1908).

HAWFINCH, *Coccothraustes coccothraustes*, one of the largest of the finch family (*Fringillidae*), found over nearly the whole of Europe and north Asia and in Africa north of the Atlas. It breeds in nearly all the English counties to Yorkshire. In coloration it bears some resemblance to a chaffinch, but its much larger size and enormous beak make it easily recognizable, while the singular bill-hook form of some of its wing-feathers will be found remarkable. Though frequenting gardens and orchards as well as woods, it is exceedingly shy. It has an unfortunate predilection for green peas. In winter it may gather in flocks. It is unusual in that courtship begins while the birds are still in flocks, the mated pairs then separating to find individual territories.

HAWICK, burgh of barony and police burgh, Roxburghshire, Scotland. Pop. (1921), 16,353. It is situated at the confluence of the Slitrig (which flows through the town) with the Teviot, 10 m. S.W. of Jedburgh by road and 52½ m. S.E. of Edinburgh by the L.N.E.R. The only church of historical interest is that of St. Mary's, the third of the name, built in 1763. The first church, believed to have been founded by St. Cuthbert (d. 687), was succeeded by one dedicated in 1214, which was the scene of the seizure of Sir Alexander Ramsay of Dalhousie in 1342 by Sir William Douglas. The Buccleuch memorial hall, commemorating the 5th duke of Buccleuch, contains a technical school and a museum. The Moat or Moot hill at the south end of the town is an earth mound 30 ft. high and 300 ft. in circumference, possibly the place where formerly the court of the manor met. The Baron's tower, founded in 1155 by the Lovels, lords of Branksome and Hawick, and afterwards the residence of the Douglasses of Drumlanrig, is said to have been the only building that was not burned down during the raid of Thomas Radcliffe, 3rd earl of Sussex, in April 1570. Bridges across the Teviot connect Hawick with the suburb of Wilton, and St. Leonard's park and race-course are

situated on the Common, 2 m. S.W. The town is governed by a provost, bailies and council. The leading industries are the manufacture of hosiery, yarn and tweeds. There are, besides, dye works, saw-mills, iron-foundries and nursery gardens. The markets for live stock are also important.

In 1537 Hawick received from Sir James Douglas of Drumlanrig a charter which was confirmed by the infant Queen Mary in 1545, and remained in force until 1861, when the corporation was reconstituted by act of parliament. Sir Robert Umfraville (d. 1436), governor of Berwick, burned the town about 1417. In 1514, the year after the battle of Flodden, in which Hawick burghers had suffered severely, a number of young men routed an English force at Hornshole on the Teviot 2 m. below the town. This event is celebrated every June in the ceremony of "Riding the Common"—in which a facsimile of the captured pennon is carried in procession to the accompaniment of a chorus "Teribus, ye Teri Odin," supposed to be an invocation to Thor and Odin—a survival of Northumbrian paganism. An equestrian statue was erected in 1914 to mark the quater-centenary of the victory.

Two m. S.W. of Hawick is the massive peel of Goldielands—the "watch-tower of Branksome," a typical Border stronghold. One mile beyond it, occupying a commanding site on the left bank of the Teviot, stands Branksome castle, the Branksome hall of *The Lay of the Last Minstrel*, once owned by the Lovels, but since the middle of the 15th century the property of the Scotts of Buccleuch. It was destroyed in 1570 and was rebuilt the next year, the peel forming part of the modern mansion.

HAWK, a word of indefinite meaning, often used to include all diurnal birds of prey not vultures or eagles. In a more restricted sense, it excludes buzzards, falcons, harriers and kites. Hawks are characterized by short wings, long legs, and a bill curved down directly from the cere, or bare patch at the base, with the edges of the upper beak wavy but not notched. The female is always considerably larger than the male, the irides are yellow, deepening with age to orange or red, and the plumage is striped below in the young, barred in the adult. The largest is the goshawk (*q.v.*), while the male of the smallest, *Accipiter tinus*, is about the size of a song-thrush. Arboreal in habit, they feed largely on birds which they seize in their talons with a rapid swoop.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

AMERICAN SPARROW HAWK (*FALCO SPARVERIUS*), LIKE THE KESTREL

The European sparrow-hawk (*A. nisus*) extends from Ireland to Japan and southward to India and North Africa. Two allied forms replace it in North America, the sharp-shinned hawk, *A. fuscus*, and Cooper's hawk, *A. cooperi*. *A. tinus* is South American and numerous other species occur there, in Asia, Australia, Africa, and south-east Europe. (See FALCONRY.)

HAWKE, EDWARD HAWKE, BARON (1705-1781), British admiral, son of a barrister, entered the navy on Feb. 20, 1720, and served the time required to qualify him to hold a lieutenant's commission on the North American and West Indian stations. When war began with Spain in 1739, he served as captain of the "Portland" (50) in the West Indies. His ship was old and rotten. She nearly drowned her captain and crew, and was broken up after she was paid off in 1742. In the following year Hawke was appointed to the "Berwick" (70), and fought his ship in the ill-managed battle of Toulon on Jan. 11, 1744. In July 1747 he attained flag rank, and was named second in command of the Channel fleet. He was sent in command of the fourteen ships detached to intercept a French convoy on its way to the West Indies. On Oct. 14, 1747 he fell in with it in the Bay of Biscay, attacked at once, and captured six of the eight French ships.

In 1747 Hawke had been elected M.P. for Portsmouth, which he continued to represent for thirty years, though he can seldom have been in his place, and it does not appear that he often spoke. In the interval between the war of the Austrian Succession and

the Seven Years' War, Hawke was almost always on active service. From 1748 till 1752 he was in command at home, and he rehoisted his flag in 1755 as admiral in command of the Western Squadron. In June 1756 the news of John Byng's retreat from Minorca reached England. Hawke was at once sent out to relieve him in the Mediterranean command, and to send him home for trial. Minorca had fallen, from want of resources rather than the attacks of the French, before he could do anything for the assistance of the garrison of Fort St. Philip. He returned to England in January 1757, and next month was promoted full admiral.

When Pitt's great ministry was formed in June 1757, Hawke was not included in the Board of Admiralty, but he was continued in command of important forces in the Channel. In the late summer of 1757 he commanded the abortive expedition against Rochefort. During the end of 1757 and the beginning of 1758 he continued cruising in the Channel in search of the French naval forces. In May of that year he was ordered to detach a squadron under the command of Howe to carry out further combined operations. He retired in June for a time on the ground of health, but happily he was able to hoist his flag in May 1759, the "wonderful year" of Garrick's song.

France was then collecting an army for the invasion of England in the Morbihan in Brittany; its transport was to be covered by a fleet to be made up by uniting the squadron at Brest with the ships at Toulon. The proposed combination of the French fleet was defeated by the annihilation of the Toulon squadron on the coast of Portugal by Boscawen in May, but the Brest fleet was still untouched and the troops were still at Morbihan. It was the duty of Hawke to prevent attack from this quarter. The way in which he discharged his task marks an epoch in the history of the British navy. Until his time, or very nearly so, it was still believed that there was rashness in keeping great ships out after September. Hawke maintained his blockade of Brest till far into November. By the care he took to obtain fresh food, and the energy he showed in pressing the Admiralty for stores, he kept his men healthy. Early in November severe gales forced him off the French coast, and he anchored in Torbay. His brief absence allowed the French admiral, M. de Conflans, time to put to sea, and to steer for the Morbihan. Hawke, who had left Torbay on Nov. 13, learnt of the departure of the French at sea on the 17th from a look-out ship, and followed the French admiral to the Morbihan. He sighted the French about 40 m. to the west of Belleisle on the morning of Nov. 20. The British fleet was of twenty-one sail, the French of twenty. There was also a small squadron of British ships engaged in watching the Morbihan as an inshore squadron, which was in danger of being cut off. After making a motion to give battle, Conflans changed his mind and gave the signal to his fleet to steer for the anchorage at Quiberon, thinking that the British admiral would not dare to follow him, for the coast is one of the most dangerous in the world, and the wind was rising to a storm. Hawke, however, caught up the rear of the French fleet in the afternoon. It was dark before the action began in Quiberon Bay. Five ships only were taken or destroyed, but others ran ashore, and the French navy as a whole lost all confidence. Two British vessels were lost, but the price was little to pay for such a victory. No more fighting remained to be done. The fleet in Quiberon Bay suffered from want of food, and its distress is recorded in the lines:—

"Ere Hawke did bang
Mounseer Conflang
You sent us beef and beer;
Now Mounseer's beat,
We've nought to eat,
Since you have nought to fear."

Hawke returned to England in Jan. 1760 and had no further service at sea. Sixteen years later (1776) he received a peerage as Baron Hawke of Towton. From 1766 to 1771 he was first lord of the Admiralty. His administration was much criticized. He was no favourite with Chatham's partizans. It is very credible that, having spent all his life at sea, his faculty did not show in the uncongenial life of the shore. As an admiral at sea and on his own element Hawke had no superior. On his death on the 17th of

October 1781 his title passed to his son, Martin Bladen (1744–1805), and it is still held by his descendants, the 7th Baron (b. 1860) being the well-known cricketer who for so many years captained the Yorkshire eleven.

There is a portrait of Hawke in the Painted Hall at Greenwich. His *Life* by Montagu Burrows (1883) superseded all earlier authorities; it is supplemented in a few early particulars by Sir J. K. Laughton's article in the *Dict. Nat. Biog.* (1891).

HAWKER, ROBERT STEPHEN (1803–1875), English antiquary and poet, was born at Stoke Damerel, Devonshire. He became vicar of Morwenstow, a village on the north Cornish coast, in 1834. He had an eccentric and powerful personality and was the original of Mortimer Collins's Canon Tremaine in *Sweet and Twenty*. He died in Plymouth on Aug. 15, 1875. Before his death he was formally received into the Roman Catholic Church, a proceeding which aroused a bitter newspaper controversy. The best of his poems is *The Quest of the Sangraal: Chant the First* (Exeter, 1864). Among his *Cornish Ballads* (1869) the most famous is on "Trelawny," the refrain of which, "And shall Trelawny die," etc., he declared to be an old Cornish saying.

See *The Life and Letters of R. S. Hawker* (1905) by his son-in-law, C. E. Byles, which contains a bibliography of his works, now very valuable to collectors. See also Boase and Courtney, *Bibliotheca Cornubiensis*. His *Poetical Works* (1879) and his *Prose Works* (1893) were edited by J. G. Godwin. A complete edition of his poems by C. E. Byles, with the title *Cornish Ballads and other Poems*, appeared in 1904.

HAWKERS and PEDLARS. The designations of itinerant dealers who convey their goods from place to place to sell. The word "hawker" seems to have come into English from the German or Dutch in the early 16th century. In an act of 1533 (25 Henry VIII. c. 9, s. 6) we find "Sundry evill disposed persons which commonly beene called haukers . . . buying and selling of Brasse and Pewter." The earlier word for such an itinerant dealer is "huckster," which is found in 1200, "For that they have turned God's house intill hucksteress bothe" (*Ormulum* 15, 817).

"Pedlar" occurs much earlier than the verbal form "to peddle," which is therefore a derivative from the substantive. The origin is to be found in the still older word "pedder," one who carries about goods for sale in a "ped," a basket or hamper. This is now only used dialectically and in Scotland. The French term for a hawker or pedlar of books, *colporteur*, has been adopted by the Bible Society and other English religious bodies as a name for itinerant vendors and distributors of Bibles and other religious literature.

The occupation of hawkers and pedlars has been regulated in Great Britain, and the two classes have also been technically distinguished. The Pedlars act, 1871, defines a pedlar as "any hawker, pedlar, petty chapman, tinker, caster of metals, mender of chairs, or other person who, *without* any horse or other beast bearing or drawing burden, travels and trades on foot and goes from town to town or to other men's houses, carrying to sell or exposing for sale any goods, wares or merchandise . . . or selling or offering for sale his skill in handicraft." Any person who acts as a pedlar must have a certificate, which is to be obtained from the chief officer of police of the police district in which the person applying for the certificate has resided during one month previous to his application. He must satisfy the officer that he is above 17 years of age, is of good character, and in good faith intends to carry on the trade of a pedlar. The fee for a pedlar's certificate is five shillings, and the certificate remains in force for a year from the date of issue. The act requires a register of certificates to be kept in each district, and imposes a penalty for the assigning, borrowing or forging of any certificate. It does not exempt any one from vagrant law, and requires the pedlar to show his certificate on demand to certain persons. It empowers the police to inspect a pedlar's pack, and provides for the arrest of an uncertificated pedlar or one refusing to show his certificate. A pedlar's certificate is not required by commercial travellers, sellers of vegetables, fish, fruit or victuals, or sellers in fairs. The Hawkers act, 1888, defines a hawker as "anyone who travels *with* a horse or other beast of burden, selling goods," etc. An excise licence (expiring on March 31 in each year) must be taken out by

every hawker in Great Britain. The duty imposed upon such licence is £2. A hawker's licence is not granted, otherwise than by way of licence, except on production of a certificate signed by a clergyman and two householders of the parish or place wherein the applicant resides, or by a justice of the county or place, or a superintendent or inspector of police for the district, attesting that the person is of good character and a proper person to be licensed as a hawker. There are certain exemptions from taking out a licence—commercial travellers, sellers of fish, coal, etc., sellers in fairs, and the real worker or maker of any goods. The act also lays down certain provisions to be observed by hawkers and others, and imposes penalties for infringements. In the United States there is no distinction between the words pedlar and hawker. In that country, and, in a lesser degree, in Great Britain, the improvement in transportation, the increase of the chain or multiple shops and the growth of the mail order business, has caused a great decrease in the number of pedlars. In their place the canvassing salesman has become common, the distinction between the two being that the canvassing salesman takes orders from samples, or from pictures of the goods, whereas the pedlar carries his stock with him.

HAWKESWORTH, JOHN (c. 1715–1773), English miscellaneous writer, succeeded Samuel Johnson in 1744 as compiler of the parliamentary debates for the *Gentleman's Magazine*, and from 1746 to 1749 contributed poems signed Greville, or H. Greville, to that journal. In company with Johnson and others he started a periodical called *The Adventurer*, which ran to 140 numbers, of which 70 were from the pen of Hawkesworth himself. He died on Nov. 16, 1773, and was buried at Bromley, Kent, where he and his wife had kept a school. Hawkesworth was a close imitator of Johnson both in style and thought, and was at one time on very friendly terms with him. It is said that he presumed on his success, and lost Johnson's friendship as early as 1756. He edited the works of Swift (12 vols., 1754–55, and 27 vols., 1766–79), and Cook's papers relative to his first voyage (3 vols., 1773), and was the author or adapter of several plays.

HAWKHURST, a town in Kent, England, 47 m. S.E. of London, on a branch of the S.R. Pop. (1921) 3,120. It lies mainly on a ridge above the valley of the Kent Ditch, a tributary of the Rother. The neighbouring country is hilly and well wooded, and the church of St. Lawrence, founded from Battle abbey in Sussex, is Decorated and Perpendicular, its east window belonging to the earlier period.

HAWKINS or **HAWKINS, SIR JOHN** (1532–1595), English admiral, was born at Plymouth in 1532, and belonged to a family of Devon shipowners and skippers. His father, William Hawkins (d. 1553), thrice represented Plymouth in parliament, and is described by Hakluyt as one of the principal sea-captains in the west parts of England; his elder brother, also called William (d. 1589), was closely associated with him in his Spanish expeditions, and took an active part in fitting out ships to meet the Armada; and his nephew, the eldest son of the last named and of the same name, sailed with Sir Francis Drake to the South Sea in 1577, and served as lieutenant under Edward Fenton (q.v.) in the expedition which started for the East Indies and China in 1582. His son, Sir Richard Hawkins, is separately noticed.

Sir John Hawkins was bred to the sea in the ships of his family. When the great epoch of Elizabethan maritime adventure began, he took an active part by sailing to the Guinea coast, where he robbed the Portuguese slavers, and then smuggled the negroes he had captured into the Spanish possessions in the New World. After a first successful voyage in 1562–1563, two vessels which he had rashly sent to Seville were confiscated by the Spanish government. With the help of friends, and the open approval of the queen, who hired one of her vessels to him, he sailed again in 1564, and repeated his voyage with success, trading with the Creoles by force when the officials of the king endeavoured to prevent him. These two voyages brought him reputation, and he was granted a coat of arms with a demi-Moor, or negro, chained, as his crest. The rivalry with Spain was now becoming very acute, and when Hawkins sailed for the third time in 1567, he went in fact, though not technically, on a national venture. Again

he kidnapped negroes, and forced his goods on the Spanish colonies. Encouraged by his discovery that these settlements were small and unfortified, he on this occasion ventured to enter Vera Cruz, the port of Mexico, after capturing some Spaniards at sea to be held as hostages. He alleged that he had been driven in by bad weather. The falsity of the story was glaring, but the Spanish officers on the spot were too weak to offer resistance. Hawkins was allowed to enter the harbour, and to refit at the small rocky island of San Juan de Ulloa by which it is formed. Unfortunately for him, and for a French corsair whom he had in his company, a strong Spanish force arrived, bringing the new viceroy. The Spaniards pretended to accept the arrangement made before their arrival, and then when they thought he was off his guard attacked him on Sept. 24. Only two vessels escaped, his own, the "Minion," and the "Judith," a small vessel belonging to his cousin Francis Drake. The voyage home was miserable, and the sufferings of all were great.

For some years Hawkins did not return to the sea, though he continued to be interested in privateering voyages as a capitalist. In the course of 1572 he recovered part of his loss by pretending, with the knowledge of Lord Burleigh, to betray the queen for a bribe to Spain. In 1573 he became treasurer of the navy in succession to his father-in-law Benjamin Gonson, and then comptroller; and for the rest of his life he was the principal administrative officer of the navy. Burleigh noted that he was suspected of fraud in his office, but the queen's ships were kept by him in good condition. In 1588 he served as rear-admiral against the Spanish Armada and was knighted. In 1590 he was sent to the coast of Portugal to intercept the Spanish treasure fleet, but did not meet it. In giving an account of his failure to the queen he quoted the text "Paul doth plant, Apollo doth water, but God giveth the increase," which exhibition of piety is said to have provoked the queen into exclaiming, "God's death! This fool went out a soldier, and has come home a divine." In 1595 he accompanied Drake on another treasure-hunting voyage to the West Indies, which was even less successful, and he died at sea off Porto Rico on the 12th of November 1595.

Contemporary evidence can be produced to show that Hawkins was greedy, unscrupulous and rude. But if he had been a more delicate man he would not have risked the gallows by making piratical attacks on the Portuguese and by appearing in the West Indies as an armed smuggler; and in that case he would not have played an important part in history by setting the example of breaking down the pretension of the Spaniards to exclude all comers from the New World. His morality was that of his time, whether in England or elsewhere.

See R. A. J. Walling, *A Sea-dog of Devon* (1907); and Southey in his *British Admirals*, vol. iii. The original accounts of his voyages compiled by Hakluyt have been reprinted by the Hakluyt Society, with a preface by Sir C. R. Markham.

HAWKINS, SIR JOHN (1719–1789), English writer on music, was born on March 30, 1719, in London, the son of an architect. He studied law, devoting his leisure hours to his favourite study of music. A wealthy marriage in 1753 enabled him to indulge his passion for acquiring rare works of music; he bought, for example, the collection formed by Dr. Pepusch, and subsequently presented it to the British Museum. His great work, the *General History of the Science and Practice of Music*, in 5 vols. (republished 1853 and 1876), was brought out in 1776, when the first volume of Burney's history also appeared. The relative merits of the two works were eagerly discussed by contemporary critics. But Hawkins's, which is essentially a collection of rare and valuable pieces of music with a more or less continuous commentary, has in a fact a different aim from Burney's. Hawkins wrote also a biography of Samuel Johnson, with whom he was intimately acquainted. He died on May 21, 1789.

HAWKINS or **HAWKINS, SIR RICHARD** (c. 1562–1622), English seaman, was the only son of Admiral Sir John Hawkins (q.v.) by his first marriage. In 1582 he accompanied his uncle, William Hawkins, to the West Indies. In 1585 he was captain of a galliot in Drake's expedition to the Spanish Main, in 1588 he commanded a queen's ship against the Armada, and in 1590

served with his father's expedition to the coast of Portugal. In 1593 he purchased the "Dainty," a ship originally built for his father and used by him in his expeditions, and sailed for the West Indies, the Spanish Main and the South Seas to prey on the oversea possessions of the king of Spain. Hawkins, however, in an account of the voyage written 30 years afterwards, maintained that his expedition was undertaken purely for the purpose of geographical discovery. After visiting the coast of Brazil, the "Dainty" passed through the Straits of Magellan, and in due course reached Valparaiso. Having plundered the town, Hawkins pushed north, and in June 1594, a year after leaving Plymouth, arrived in the Bay of San Mateo. Here the "Dainty" was attacked by two Spanish ships. Hawkins was hopelessly outmatched, and at last, when he himself had been severely wounded, many of his men killed, and the "Dainty" was nearly sinking, he surrendered on the promise of a safe-conduct out of the country for himself and his crew. Through no fault of the Spanish commander this promise was not kept. In 1597 Hawkins was sent to Spain, and imprisoned first at Seville and subsequently at Madrid. He was released in 1602, and, returning to England, was knighted in 1603. In 1604 he became member of parliament for Plymouth and vice-admiral of Devon, a post which, as the coast was swarming with pirates, was no sinecure. In 1620-1621 he was vice-admiral, under Sir Robert Mansell, of the fleet sent into the Mediterranean to reduce the Algerian corsairs. He died in London on April 17, 1622.

See his *Observations in his Voiage into the South Sea* (1622), republished by the Hakluyt Society.

HAWKSBILL (*Eretmochelys imbricata*), a marine turtle, so called from the shape of its snout, common in the tropical parts of the Indian, Pacific and Atlantic oceans, and producing the tortoiseshell (*q.v.*) of commerce. Its flesh is valueless, though the eggs are edible. The hawkbill is carnivorous. (See TORTOISE.)

HAWKSHAW, SIR JOHN (1811-1891), English engineer, was educated at Leeds grammar school. He became chief engineer of the Lancashire and Yorkshire railway, for which he constructed a large number of branch lines. In 1850 he removed to London and began to practise as a consulting engineer, at first alone, but subsequently in partnership with Harrison Hayter. In London he was responsible for the Charing Cross and Cannon Street railways, together with the two bridges which carried them over the Thames; he was engineer of the East London railway, which passes under the Thames through Sir M. I. Brunel's well-known tunnel; and jointly with Sir J. Wolfe Barry he constructed the section of the Underground railway which completed the "inner circle" between the Aldgate and Mansion House stations. Hawkshaw was concerned with many railway works in all parts of the world—Germany, Russia, India, Mauritius, etc. He advocated, in opposition to Robert Stephenson, steeper gradients than had previously been thought desirable or possible, and he protested against the maintenance of the broad gauge on the Great Western, as he foresaw that it complicated railway extension.

In 1862 he became engineer of the Amsterdam ship-canal, and in the next year he may fairly be said to have been the saviour of the Suez canal by presenting a favourable report on the question to the Khedive. As a member of the International Congress to consider the construction of an interoceanic canal across Central America, he preferred the Nicaraguan route. He regarded the Panama scheme as impracticable at a reasonable cost, although publicly he expressed no opinion on the matter and left the Congress without voting. He was engineer of the Severn tunnel, one of the most notable engineering undertakings of the 19th century. He died in London on June 2, 1891.

HAWKSMOOR, NICHOLAS (1661-1736), English architect, was born in Nottinghamshire in 1661 and died in London on March 25, 1736. He became a pupil of Sir Christopher Wren, through whose influence he became deputy-surveyor at Chelsea and Greenwich hospitals and clerk of the works at Whitehall, St. James's and Westminster. He succeeded Wren as surveyor-general of Westminster Abbey. Hawksmoor shared in much of the work done by Wren and Sir J. Vanbrugh; the early Gothic de-

signs of the two towers of All Souls', Oxford, north quadrangle, and the library at Queen's college, Oxford, appear, however, to be his own. He also designed several London churches, notably St. Mary Woolnoth (1716-19) and St. George's, Bloomsbury (1720-30).

See H. S. Goodhart-Rendel, *Nicholas Hawksmoor* (1924).

HAWKWEED, the name given to species of the genus *Hieracium*, of the family Compositae, containing some 450 species inhabiting the northern hemisphere, South Africa and the Andes. The flowering heads, generally yellow, are borne, often several at a time, on an elongated axis, the component flowers being ligulate. Various hawkweeds are troublesome weeds, especially in grass-land. Some 20 or more species occur in the British Isles and upwards of 40 species are found in North America, including several from the Old World which are widely naturalized as weeds. Of the latter, the orange hawkweed or devil's paint-brush (*H. aurantiacum*), of south Europe, sometimes cultivated, and the field hawkweed (*H. pratense*) have become pestiferous. G. Mendel (*q.v.*) employed hawkweeds in some of his experiments in heredity, but they proved extremely unsatisfactory material on account of the small size of the individual flowers and because some are parthenogenetic. (See COMPOSITAE.)

HAWKWOOD, SIR JOHN (d. 1394), an English adventurer who attained great wealth and renown as a condottiere in the Italian wars of the 14th century. His name is variously spelt as Haccoude, Aucud, Aguto, etc., by contemporaries. He was perhaps the son of a tanner of Hedingham Sibil in Essex, and was apprenticed in London, whence he went, in the English army, to France under Edward III. and the Black Prince. He was certainly of knightly rank, which he may have received from Edward III. On the peace of Bretigny in 1360, he collected a band of men-at-arms, and moved southward to Italy, where the White Company, as his men were called, assisted the marquis of Monferrato against Milan in 1362-63, and the Pisans against Florence in 1364. After several campaigns in central Italy, Hawkwood in 1368 entered the service of Bernabo Visconti. In 1369 he fought for Perugia against the pope, and in 1370 for the Visconti against Pisa, Florence and other enemies. In 1372 he defeated the marquis of Monferrato, but soon afterwards, resenting the interference of a council of war resigned his command, and the White Company passed into the papal service, in which he fought against the Visconti in 1373-1375. In 1375 the Florentines agreed to pay him and his companion 130,000 gold florins in three months on condition that he would not fight against them; and in the same year the priors of the arts and the gonfalonier awarded him a pension of 1,200 florins per annum. In 1377, under the orders of the cardinal Robert of Geneva, legate of Bologna, he massacred the inhabitants of Cesena, but in May of the same year, disliking the executioner's work put upon him by the legate he joined the anti-papal league, and married, at Milan, Donnina, an illegitimate daughter of Bernabo Visconti. In 1378 and 1379 Hawkwood was constantly in the field; he quarrelled with Bernabo in 1378, and entered the service of Florence, receiving, as before 130,000 gold florins. He served the republic up to 1382, when for a time he was an English ambassador at the papal court. He fought in Naples in 1383 for the marquis of Padua against Verona in 1386, and in 1388 made an unsuccessful effort against Gian Galeazzo Visconti, who had murdered Bernabo. In 1390 the Florentines took up the war against Gian Galeazzo in earnest, and appointed Hawkwood commander-in-chief. His campaign against the Milanese army in the Veronese and the Bergamask was a triumph of generalship, and in 1392 Florence forced a satisfactory peace from Gian Galeazzo. His latter years were spent near Florence. On his death in 1394 the republic gave him a public funeral. Paolo Uccelli painted his portrait in terre-verte on the inner façade of the cathedral.

Of his children by Donnina Visconti, who was probably his second wife, the eldest daughter married Count Brezaglia of Porciglia, podestà of Ferrara, who succeeded him as Florentine commander-in-chief, and another a German condottiere, Conrad Prospergh. His son, John, returned to England and settled at Hedingham Sibil. The children of the first marriage were two

sons and three daughters, of whom the youngest married John Shelley, an ancestor of the poet.

G. Alger in *Register and Magazine of Biography*, v. 1.; and article in *Dict. Nat. Biog.*

HAWLEY, HENRY (c. 1679–1759), British lieutenant-general, entered the army, it is said, in 1694. Under Cumberland's orders he led the cavalry in the campaign of Culloden, and at that battle his dragoons gained an evil name by their ruthless butchery of the fugitive rebels. He died at Portsmouth in 1759.

HAWORTH, an urban district in the Keighley parliamentary division of the West Riding of Yorkshire, England, 10 m. N.W. of Bradford, on a branch of the L.M.S. railway. Pop. (1921), 6,600. It is picturesquely situated at an altitude of 600 ft., surrounded by moorland, on the steep slope of a tributary valley of the Worth, which flows north to join the Aire. The parsonage was the home of Charlotte and Emily Brontë, and a memorial near the west window of St. Michael's church bears their name, and that of their father, the Rev. Patrick Brontë. In 1895, a museum was opened by the Brontë Society, and in Aug. 1928 the parsonage was presented by Sir James Roberts to the Brontë Society as a permanent museum and library. The worsted industry of Haworth is important.

HAWSER, a small cable or thick rope used at sea for the purposes of mooring or warping, in the case of large vessels made of steel. When a cable or tow line is made of three or more small ropes it is said to be "hawser-laid." The "hawse" of a ship is that part of the bows where the "hawse-holes" are made. These are two holes cut in the bows of a vessel for the cables to pass through, having small cast-iron pipes, called "hawse-pipes," fitted into them to prevent abrasion. In bad weather at sea these holes are plugged up with "hawse-plugs" to prevent the water entering.

HAWTHORN, an eastern suburb and residential area of Melbourne, Australia. (See MELBOURNE.)

HAWTHORN, the common name for *Crataegus*, in botany, a genus of shrubs or small trees belonging to the family Rosaceae, native of the north temperate regions, especially America. It is represented in the British Isles by the hawthorn, white-thorn or may, *C. oxyacantha*, a small, round-headed, much-branched tree, 10 to 20 ft. high, the branches often ending in single sharp spines. The leaves, which are deeply cut, are 1 to 2 in. long and very variable in shape. The flowers are sweet-scented, in flat-topped clusters, and $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter, with five spreading white petals alternating with five persistent green sepals, a large number of stamens with pinkish-brown anthers, and one to three carpels sunk in the cup-shaped floral axis. The fruit, or haw, as in the apple, consists of the swollen floral axis, which is usually scarlet, and forms a fleshy envelope surrounding the hard stone.

The common hawthorn is a native of Europe as far north as 60 $\frac{1}{2}$ ° in Sweden, and of North Africa, western Asia and Siberia, and has been naturalized in North America and Australia. It thrives best in dry soils, and in height varies from 4 or 5 to 12, 15 or, in exceptional cases, as much as between 20 and 30 ft. Hawthorn has been for many centuries a favourite park and hedge plant in Europe, and numerous varieties have been developed by cultivation; these differ in the form of the leaf, the white, pink or red, single or double flowers, and the yellow, orange or red fruit. In England the hawthorn, owing to its hardiness and closeness of growth, has been employed for enclosure of land since the Roman occupation, but for ordinary field edges it is believed it was not generally in use till about the end of the 17th century. James I. of Scotland, in his *Quair*, ii. 14 (early 15th century), mentions the "hawthorn hedges knet" of Windsor Castle. The first hawthorn hedges in Scotland are said to have been planted by soldiers of Cromwell at Inch Buckling Brae in East Lothian and Finlarig in Perthshire. Annual pruning, to which the hawthorn is particularly amenable, is necessary if the hedge is to maintain its compactness and sturdiness. When the lower part shows a tendency to go bare the strong stems may be "plashed," i.e., split,

bent over and pegged to the ground so that new growths may start. The wood of the hawthorn is white in colour, with a yellowish tinge. Its great hardness, however, renders it valuable for the manufacture of various articles, such as the cogs of mill-wheels, flails and mallets, and handles of hammers and for engraving. The custom of employing the flowering branches for decorative purposes on the 1st of May is of very early origin; but since the

FROM COOPER AND WESTELL, "SHRUBS OF THE BRITISH ISLES" (J. M. DENT & SONS)

FLOWERING BRANCH OF THE ENGLISH HAWTHORN (*CRATAEGUS OXYACANTHA*), A SHRUB SOMETIMES 20 FEET HIGH, WIDELY PLANTED IN EUROPE AS A PARK AND FIELD HEDGE. BELOW ARE THE FRUITS (HAWS)

alteration in the calendar the tree has rarely been in full bloom in England before the second week of that month. Branches of the Glastonbury thorn, *C. oxyacantha*, var. *praecox*, which flowers both in Dec. and in spring, were formerly highly valued in England, on account of the legend that the tree was originally the staff of Joseph of Arimathea.

The number of species in the genus is from 70 to 100 according to the view taken as to whether or not some of the forms, especially of those occurring in the United States, represent distinct species. *C. coccinea*, a native of Canada and the eastern United States, with bright scarlet fruits, was introduced into English gardens towards the end of the 17th century. *C. Crus-Galli*, with a somewhat similar distribution and introduced about the same time, is a very decorative species with showy, bright red fruit, often remaining on the branches till spring, and leaves assuming a brilliant scarlet and orange in the autumn; numerous varieties are in cultivation. *C. Pyracantha*, known in gardens as pyracantha, is evergreen and has white flowers, appearing in May, and fine scarlet fruits of the size of a pea which remain on the tree nearly all the winter. It is a native of south Europe and was introduced into Britain early in the 17th century.

HAWTHORNE, NATHANIEL (1804–1864) American romancer, was born at Salem (Mass.) on July 4, 1804, and died at Plymouth (N.H.) on May 19, 1864. He was the most distinguished craftsman of the New England school of letters. His quiet life, wholly detached from the major activities of the times, was largely given over to brooding solitude. Brought up in the old seaport town, and returning there to live for long periods of time, he was a child of the Salem eclipse. The Salem that nourished his imagination was already living on its memories—memories that ran back to the earliest days of the Massachusetts Bay Colony, and were darkened by a waning prosperity. The seat of government early passed to Boston and with its passing a deep provincialism settled on the countryside that came to sinister expression in the unhappy witch-craft persecutions. In the 18th

century the town enjoyed a temporary prosperity from overseas commerce, and thrifty sea-captains built dignified houses out of the profits of the China trade. Then came a swift decline, the passing of commerce to other ports, and a musty quiet about the wharves.

Of this grim decay the Hathorne family—the “w” was inserted in the name by Nathaniel in early manhood—might well seem a striking symbol to one who inherited only the shadow of its former dignity. For a time the Hathorne family were important members of the local gentry but later the family fortunes declined and the Hathornes slipped from their proud position. “From father to son, for above 100 years, they followed the sea,” but they amassed no wealth and built no great house in Salem. Capt. Nathaniel Hathorne, father of the novelist, married Elizabeth Clark Manning, daughter of a neighbour, but a few years later he died, leaving his wife and three small children in meagre circumstances. It was a strange household in which the boy was reared, a sort of Puritan nunnery with the mother and daughters slipping wraith-like from room to room, fearful of every contact, given to solitude—a household infected with gloom, the natural spirits repressed, mirthless and passionless except for the one consuming passion of renunciation, yet enjoying a certain grim Puritan culture and sustained by a deep family pride that remembered greater days and would hide its genteel poverty from a critical world.

From such an upbringing Hawthorne got those mental characteristics that set him so completely apart from his fellows—a strong pride, a sense of aloofness and alienation from the common interests, a suspicious, defensive hostility towards a world that ignored his timid gestures of *rapprochement*. A barrier slowly rose about his soul over which he was never willing or able to climb, and within this barrier he dwelt alone, sceptical, critical, keenly observant, weaving the threads of fancy into fantastic shapes, discovering obscure symbolisms in every substantial fact, and investing the children of his imagination with a rare ascetic beauty. From the solitude of those early years he never escaped. At nine he injured a foot and for months was shut up in the house with only crutches to help him about. At 14 he went with the family to Raymond, a wilderness hamlet in Maine, and there by the quiet waters of Sebago lake he dreamed and played alone. Three years later, in 1821, he was sent by his uncles to Bowdoin college, a raw little school at Brunswick (Me.), where he spent four years with little other profit than the making of two friendships that were to endure through life—with Horatio Bridge who was to push him lovingly towards public recognition, and with Franklin Pierce, afterwards President of the United States, who was to send him to the American consulate at Liverpool and make possible his European experience.

Upon his graduation in 1825 he returned to Salem, where his manner of life was already predetermined. The passion of the artist was stirring within him, a passion somewhat pale and austere as became a child of Puritanism, but infused with a fine integrity; and under the compulsions of that passion he set himself to master the craft of the short story, till then scarcely practised in America. He slipped quietly back into the shadowy existence of the Herbert street house and the grim past of Salem with its tales of his Hathorne ancestry. It was, he said, “the sensuous sympathy of dust for dust,” a “strange, indolent, unjoyous attachment,” that wove about him a net too strong to break. Twelve years he spent thus, serving a laborious apprenticeship to his art, without masters, learning the secret of smooth-flowing sentences, discovering how to weave harsh words into soft tapestries and throw about them an atmosphere of dark loveliness. It was an unhappy time, harassed by pride and self-depreciation and longing; but it taught him the art of creative selection, and endowed his pen with the gift of emotional unity. From the labours of those years little was salvaged—*Fanshawe*, an abortive romance he later rejected, some fugitive stories in obscure magazines, some hack work, and at last 18 stories and sketches published in 1837 under the title *Twice Told Tales*. The little volume thus timidly offered to an indifferent public made scarcely a ripple; yet certain of the stories, like “The Minister’s Black Veil,” were finished products of the art he had

been perfecting during his prentice years, and prophetic of the path his maturer art was to follow.

It was while he was enjoying the modest reputation that came from the publication of his volume that he found the one great contentment of his life in his love for Sophia Peabody. The Peabodys were old Salem stock that had got on but indifferently well till the family fortunes were taken in charge by the eldest daughter. Elizabeth Peabody was a capable woman, responsive to all the current social enthusiasms and aflame with the New England passion for learning. She was an abolitionist, a transcendentalist, an assistant to Bronson Alcott in the Temple school, and a sympathetic friend to every Utopian dreamer of the times. On the removal of the family to Boston she set up a book-shop that soon became the unofficial headquarters of the transcendental movement. From it was issued *The Dial*, as well as three volumes of Hawthorne’s children’s stories. It was here that Hawthorne came into intimate contact with the vigorous intellectual life of the New England Renaissance. He was not greatly influenced by the body of transcendental thought, and even less sympathetic with the strident reform movements. He contemplated the current enthusiasms with a cool, detached scepticism that came to expression later in *The Blithedale Romance*. His opinion of civilization is somewhat mordantly suggested in *The New Adam and Eve*, but he considered the expectations of the Utopians to be ill founded and in the sardonic tale of *Earth’s Holocaust* he satirized the enthusiasm of reformers. He was more concerned in securing a competence than in refashioning civilization and accepted a post in the Boston customs house, but after 27 months’ experience measuring coal, he invested his slender savings in the communistic settlement at Brook farm, in West Roxbury, and in April 1841 took up his residence there. But he soon found communal living uncongenial, and the following spring he withdrew and in July married Sophia Peabody and settled in the Old Manse at Concord. There were spent the three happiest years of his life, and the fruits of his somewhat indolent labours appeared in *Mosses from an Old Manse*, published in 1846, a collection of short stories that made no advance over the earlier work.

But the earnings of his pen were meagre and uncertain and his friends took advantage of a new Democratic administration to secure Hawthorne a post in the Salem customs house. In spite of such tales as *The Snow Image*, *The Great Stone Face* and *Ethan Brand*, the three years spent there were not fruitful, and it was a stroke of good fortune to be thrown out of his place by village politics. His creative period lay just ahead. He was 45 when he sat down to write a story that had long been haunting his mind and that kindled his imagination as no other was ever to do. Written with morose intensity and great diffidence, in the midst of harassing troubles, *The Scarlet Letter* was issued in April 1850. Its popular success was immediate and at last Hawthorne had ceased to be “the obscurest man of letters in America.” With the flowering of his creative powers a new restlessness seized upon him. He quitted Salem with its depressing memories, removed to Lenox, then to West Newton, then back to Concord, where the family established itself at The Wayside. During the winter at Lenox he wrote at high pressure *The House of the Seven Gables*, published in 1851, and at West Newton, close to Brook Farm, *The Blithedale Romance*, published the next year. In 1853 he received the appointment to the Liverpool consulate, and he set forth on his long-delayed pilgrimage to the old world—a pilgrimage that was to last seven years, four of them spent at Liverpool, a year and a half in Italy, and a year again in England, at Whitby and Redcar, and finally at Leamington, where in November 1859 he completed *The Marble Faun*, published early the next year under the English title *Transformation*. In the summer of 1860 he returned to The Wayside, somewhat regretfully quitting the old home that he had come to love without quite understanding. Four years of life remained to him, but he accomplished little. The war came on, his health was breaking, and the work of writing wearied and depressed him. *Septimius Felton*, *The Dolliver Romance* and *Doctor Grimshawe’s Secret*, are only rejected fragments from an old man’s workshop. From his note-books he salvaged enough material for an unimportant volume entitled *Our*

Old Home; but his work was done. The world he had known was being destroyed by the Civil War and in the midst of battles he quietly faded out of life.

Hawthorne's range as a creative artist was narrow, but within the self-imposed bounds his imagination played freely. He was the romancer of a grim Puritan past that both fascinated and repelled him. He had thrown off the last vestige of Calvinistic dogma, but he could not free his mind from the spectre of sin that haunted the waking hours of his ancestors. His speculations took their rise from an inherited ethicism. He resented the inhibitions of Puritan Hebraism, but he was unwilling to trust a frank Hellenism. *The Scarlet Letter* is not a Puritan document. As he meditated on the morals of the problem of Hester and Dimmesdale his inveterate scepticism issued in revolutionary ethics that would have scandalized his ancestors. Hester is a triumphant protest against a false Hebraism. From the long discipline of suffering she emerges enriched and ennobled. Though Hawthorne's concern is always with the ethical, only at rare moments does his imagination fuse with creative passion; more frequently it glows with a subdued light, playing lambently about the theme, clothing it in quaint or fantastic symbolism. Not a rich nature, he was gifted nevertheless with a luminous mind and a fine seriousness, and his work is marked by a subtle and distinguished craftsmanship. Cut off by solitude from a fruitful contact with society he dwelt overmuch with shadows; yet in spite of the thin and tenuous quality of his themes he was as exquisite an embodiment of the conscience-ridden Puritan mind as Emerson was of Puritan idealism.

BIBLIOGRAPHY.—An excellent bibliography of Hawthorne is given in the *Cambridge History of American Literature*, vol. ii. Among the numerous editions of his works the following are desirable: Riverside edition (12 vols., Boston, 1883); Standard Library edition (15 vols., Boston, 1891)—includes the *Life* by Julian Hawthorne; New Wayside edition (13 vols., Boston, 1902). For his life see Julian Hawthorne, *Nathaniel Hawthorne and his Wife* (2 vols., Boston, 1885); Henry James, *Nathaniel Hawthorne* (London, 1879, New York, 1885, 1887), "English Men of Letters" series; Lloyd Morris, *The Rebellious Puritan: Portrait of Mr. Hawthorne* (1927); H. Gorman, *Nathaniel Hawthorne* (1927); N. Arvin, *Hawthorne* (1929). (V. L. P.)

HAWTREY, SIR CHARLES HENRY (1858–1923), actor, was born at Eton, where his father was master of the lower school, and educated at Rugby and Oxford. He took to the stage in 1881, and in 1883 adapted von Moser's *Bibliothekar* as *The Private Secretary*, which had an enormous success. He then appeared in London in a number of modern plays, in which he was conspicuous as a comedian. He was unapproachable for parts in which cool imperturbable lying constituted the leading characteristic. Among his later successes *A Message from Mars* was particularly popular in London and in America. He was knighted in 1922. He died in London on July 30, 1923.

HAWTREY, EDWARD CRAVEN (1789–1862), English educationalist, was born at Burnham on May 7, 1789, the son of the vicar of the parish. He was educated at Eton and King's college, Cambridge, and in 1814 was appointed assistant master at Eton. He was headmaster of the college from 1834–52. In 1852 he became provost of Eton; in 1854 vicar of Mapledurham. He died on Jan. 27, 1862, and was buried in the Eton college chapel. On account of his command of languages ancient and modern, he was known in London as "the English Mezzofanti," and he was a book collector of the finest taste. He made some excellent translations from the English into Italian, German and Greek. He had a considerable reputation as a writer of English hexameters and as a judge of Homeric translation.

HAXO, FRANÇOIS NICOLAS BENOÎT, BARON (1774–1838), French general and military engineer, was born at Lunéville on June 24, 1774, and entered the Engineers in 1793. After the second siege of Saragossa (1809), Napoleon made him a colonel. He fought in the Napoleonic campaigns and after the retreat from Moscow was made general of division. In 1813 he constructed the works around Hamburg which made Davout's defence possible, and commanded the Guard Engineers until he was captured at Kulm. After the Restoration Haxo remained faithful to Napoleon, and in the Hundred Days laid out the provisional fortifications of Paris and fought at Waterloo. The best work of his career as a military engineer was done after the

second restoration, in reconstructing the old Vauban and Cormontaigne fortresses. For his services he was made a peer of France by Louis Philippe (1832). Haxo, under Marshal Gérard, directed the engineers at the famous scientific siege of Antwerp, when the fortress surrendered after a siege of little more than three weeks (Dec. 23, 1832). He was after this regarded as the first engineer in Europe, and his latter years were spent in urging upon the government and the French people the fortification of Paris and Lyons, a project which was begun in his time and completed after his death. He died at Paris on June 25, 1838.

He wrote *Mémoire sur le figuré du terrain dans les cartes topographiques* (Paris, N.D.), and a memoir of General Dejean (1824).

HAXTHAUSEN, AUGUST FRANZ LUDWIG MARIA, FREIHERR VON (1792–1866), German economist, was born near Paderborn in Westphalia on Feb. 3, 1792. He wrote *Über die Agrarverfassung in den Fürstentümern Paderborn und Corvey* (1829), a work which procured for its author a commission to investigate and report upon the land laws of the Prussian provinces with a view to a new code. His exhaustive treatise, *Die ländliche Verfassung in der Provinz Preussen* (1839) and his *Studien über die innern Zustände des Volkslebens, und insbesondere die ländlichen Einrichtungen Russlands* (Hanover, 1847–52, Eng. trans. *The Russian Empire* 1856) are classic works in their subjects. He received various honours, was a member of the combined diet in Berlin in 1847 and 1848, and afterwards of the Prussian upper house. Haxthausen died at Hanover on Dec. 31, 1866.

His other works include: *Die ländliche Verfassung Russlands* (Leipzig, 1866); *Transcaucasia; Sketches of the nations and Races between the Black Sea and the Caspian* (1854), and *The Tribes of the Caucasus* (1855).

HAY, GEORGE (1729–1811), Scottish Roman Catholic divine, was born at Edinburgh on Aug. 24, 1729. Accused of sympathizing with the rebellion of 1745, he served a term of imprisonment 1746–47. He then entered the Roman Catholic Church, studied in the Scots college at Rome, and in 1759 accompanied John Geddes (1735–99), afterwards bishop of Morocco, on a Scottish mission. Ten years later he was appointed bishop of Daulis in partibus and coadjutor to Bishop James Grant (1706–78). In 1778 he became vicar apostolic of the lowland district. From 1788 to 1793, he was in charge of the Scaln seminary; in 1802 he retired to that of Aquhorties near Inverury which he had founded in 1709. He died there on Oct. 15, 1811.

His theological works, including *The Sincere Christian*, *The Devout Christian*, *The Pious Christian* and *The Scripture Doctrine of Miracles*; were edited by Bishop Strain in 1871.

HAY, GILBERT, or "SIR GILBERT THE HAYE" (fl. 1450), Scottish poet and translator, was perhaps a kinsman of the house of Errol. He has left it on record, in the Prologue to his *Buke of the Law of Armys*, that he was "chaumerlayn umquhyle to the maist worthy King Charles of France." In 1456 he was back in Scotland, in the service of the chancellor, William, earl of Orkney and Caithness.

Hay's only political work is *The Buik of Alexander the Conquerour*, of which a portion, in copy, remains at Taymouth castle. Three of his translations exist in the collection of Abbotsford: (a) *The Buik of the Laws of Armys* or *The Buik of Bataillis*, a translation of Honoré Bonet's *Arbre des batailles*; (b) *The Buik of the Order of Knichthood* from the *Livre de l'ordre de chevalerie*; and (c) *The Buik of the Governauce of Princes*, from a French version of the pseudo-Aristotelian *Secreta secretorum*. The second of these precedes Caxton's independent translation by at least ten years.

For the *Buik of Alexander* see A. Herrmann's *The Taymouth Castle MS. of Sir Gilbert Hay's Buik, etc.* (1898). The Abbotsford ms. has been reprinted by the Scottish Text Society (ed. J. H. Stevenson, 2 vols., 1901 and 1914). *The Order of Knichthood* was printed by David Laing for the Abbotsford club (1847). See also S.T.S. edition (u.s.) "Introduction," and Gregory Smith's *Specimens of Middle Scots* (1902), in which annotated extracts are given from the Abbotsford ms. the oldest known example of literary Scots prose.

HAY, IAN, pen name of John Hay Beith (1876–), British novelist, was born at Rusholme, near Manchester, on

April 17, 1876, and educated at Fettes college, Edinburgh, and St. John's college, Cambridge. At the outbreak of the World War he joined the Argyll and Sutherland Highlanders, 10th Service Batt., was mentioned in despatches and decorated with the M.C. He is best known as the author of *The First Hundred Thousand* (1915), a humorous sketch of military life in the early days of recruiting, and its sequels, *Carrying On* (1917) and *The Last Million* (1918). His novels include *Pip* (1907); *A Man's Man* (1909); *Happy-Go-Lucky* (1919, dramatized as *Tilly of Bloomsbury*); *A Safety Match* (1911, dramatized in 1921); *A Knight on Wheels* (1914); *Paid With Thanks* (1925).

HAY, JOHN (1838-1905), American statesman and author, was born at Salem, Ind., on Oct. 8, 1838. He graduated at Brown university in 1858, studied law in the office of Abraham Lincoln, was admitted to the bar in Springfield, Ill., in 1861, and soon afterwards was selected by President Lincoln as assistant private secretary, in which capacity he served till the president's death, being associated with John George Nicolay (1832-1901). Hay was secretary of the U.S. legation at Paris in 1865-67, at Vienna in 1867-69, and at Madrid in 1869-70. After his return he was for five years an editorial writer on the *New York Tribune*; in 1879-81 he was first assistant secretary of State to W. M. Evarts. Upon the inauguration of President McKinley in 1897 Hay was appointed ambassador to Great Britain, from which post he was transferred in 1898 to that of secretary of State, succeeding W. R. Day, who was sent to Paris as a member of the Peace Conference. He remained in this office until his death at Newburg, N.H., on July 1, 1905. Hay directed the peace negotiations with Spain after the war of 1898, and not only secured American interests in the imbroglio caused by the Boxers in China, but grasped the opportunity to insist on "the administrative entity" of China; influenced the Powers to declare publicly for the "open door" in China; challenged Russia as to her intentions in Manchuria, securing a promise to evacuate the country on Oct. 8, 1903. In 1904 he again urged "the administrative entity" of China and took the initiative in inducing Russia and Japan to "localize and limit" the area of hostilities. It was due largely to his management, in concert with Lord Pauncefoot, the British ambassador, that negotiations for abrogating the Clayton-Bulwer treaty and for making a new treaty with Great Britain regarding the Isthmian canal were successfully concluded at the end of 1901; subsequently he negotiated treaties with Colombia and Panama, looking towards the construction by the United States of a transisthmian canal. He arranged the settlement of difficulties with Germany over Samoa in 1899, and the settlement, by joint commission, of the disputed Alaskan boundary in 1903. As secretary of State under Presidents McKinley and Roosevelt his guidance was invaluable during a critical period in foreign affairs, and no man of his time did more to create confidence in the increased interest taken by the United States in international matters. He also represented the best American traditions in literature. He published *Pike County Ballads* (1871)—the most famous being "Little Breeches"—a volume worthy to rank with Bret Harte; *Castilian Days* (1871), recording his observations in Spain; and a volume of *Poems* (1890); with John G. Nicolay he wrote *Abraham Lincoln: A History* (1890), a monumental work indispensable to the student of the Civil War period in America, and published an edition of Lincoln's *Complete Works* (1894). The authorship of the brilliant novel *The Breadwinners* (1883) is now certainly attributed to him. Hay was an excellent public speaker; some of his best addresses are *In Praise of Omar*; *On the Unveiling of the Bust of Sir Walter Scott in Westminster Abbey*, May 21, 1897; and a memorial address in honour of President McKinley. The best of his previously unpublished speeches appeared in *Addresses of John Hay* (1906); his correspondence in *Letters of John Hay and Extracts from His Diary* (1908) and in *A Poet in Exile: Early Letters of John Hay*, ed. Caroline Ticknor (1910); and his poems in *Complete Poetical Works of John Hay* (1916).

See Lorenzo Sears, *John Hay, Author and Statesman* (1914); William Roscoe Thayer, *The Life and Letters of John Hay* (1915); James Brander Mathews, *Commemorative Tributes* (1922); Alfred L. Dennis, *Adventures in American Diplomacy 1896-1906* (1928).

HAY, market town and urban district of Breconshire, south Wales, 20 m. N.W. of Hereford with G.W.R. and L.M.S. connections. Pop. (1921) 1,533. The town occupies rising ground on the south bank of the Wye, which here separates the counties of Brecknock and Radnor but immediately below enters Herefordshire, from which the town is separated on the east by the Dulas.

Hay guards an important way into Wales between the Radnor Forest and the Black Mts. This district was heavily forested in early times and settlement was unimportant until the Norman period. Bernard de Newmarch conquered the district about 1088. The manor of Hay, which probably corresponded to some existing Welsh division, he gave to Sir Philip Walwyn, but it soon reverted to the donor, and its subsequent devolution down to its forfeiture to the crown as part of the duke of Buckingham's estate in 1521, was identical with that of the lordship of Brecknock (see BRECONSHIRE). The motte and bailey castle, probably built in Newmarch's time and rebuilt by his great-grandson William de Breos, passed on the latter's attainder to the crown, but was again seized by de Breos's second son, Giles, bishop of Hereford, in 1215, and retaken by King John in the following year. In 1231 it was burnt by Llewelyn ab Iorwerth, and in the Barons' War it was taken in 1263 by Prince Edward, but in the following year was burnt by Simon Montfort and the last Llewelyn. From the 16th century the castle has been used as a private residence.

The Welsh name of the town is Y Gelli ("the wood"), or in full (Y) Gelli ganddryll, which roughly corresponds to *Sepes Inscissa*, used by Walter Map. Its Norman name, La Haia (from the Fr. *haie*, cf. English "hedge"), was probably intended as a translation of Gelli. Hay manor, like that of Talgarth, consisted of an Englishry and a Welshry, the latter, known as Haya Wallensis, comprising the parish of Llanigon with the hamlet of Glynfach, and in this Welsh tenures and customs prevailed. The manor is specially mentioned in the act of Henry VIII. (1535) as one of those which were then taken to constitute the new county of Brecknock.

Even down to Leland's time Hay was surrounded by a "right strong wall," but the town within the wall has "wonderfully decayed," while to the west of it was a suburb with the church of St. Mary overlooking the river. This was rebuilt in 1834. The old parish church of St. John within the walls, used as a school in the 17th century, has entirely disappeared. There are 18 almshouses for poor women, built and endowed by Miss Frances Harley in 1832-36, and Gwyn's almshouses for six aged persons, founded in 1702 and rebuilt in 1878. Hay is the centre of a rich agricultural country, and its undulating landscape has a charm of peaceful well-being.

HAY, a town of Waradgery county, New South Wales, Australia, on the Murrumbidgee river, 454 m. by rail west of Sydney. Pop. 3,600. It is the cathedral town of the Anglican diocese of Riverina, the terminus of the South Western railway, and the principal depot for the wool produced at the numerous stations on the banks of the Murrumbidgee and Lachlan rivers.

HAY, grass mown and dried in the sun and used as fodder for cattle. It is properly applied only to the grass when cut, but is often also used of the standing crop. In the United States various legumes are cut for hay, as below described. Another word "hay," meaning a fence, must be distinguished; the root from which it is derived is seen in its doublet "hedge," cf. "haw-thorn," i.e., "hedge thorn." In this sense it survives in legal history in "hay bote," i.e., hedge-bote, the right of a tenant, copyholder, etc., to take wood to repair fences, hedges, etc. (see ESTOVERS), and also in "hayward" an official of a manor whose duty was to protect the enclosed lands from cattle breaking out of the common land.

The term "haymaking" signifies the process of drying and curing grass or other herbage so as to fit it for storage in stacks or sheds for future use. It was unknown in ancient times. Before its introduction into Great Britain the animals intended for beef and mutton were slaughtered in autumn and salted down; the others were turned out to fend for themselves, and often lost all the fat in the winter they had gained the previous summer.

Though every country has its own methods of haymaking, the principal stages in the process everywhere are (1) mowing, (2) drying or "making," (3) "carrying" and storage in stacks or sheds.

In a wet district such as the west of Ireland the "making" is a difficult affair, and large quantities of hay are often spoiled. On the other hand, in the dry districts of south-eastern England, it is often possible to cut and carry the hay without any special "making" as the sun and wind will dry it quickly enough to fit it for stacking up without much labour. This rule also applies to dry countries like the United States and several of the British colonies, and it is for this reason that most of the modern implements used for quickly handling a bulk of hay have been invented or improved in those countries. Forage of all kinds intended for hay should be cut at or before the flowering stage if possible. The full growth and food value of the plant are reached then, and further change consists in the formation and ripening of the seed at the expense of the leaves and stems, leaving these hard and woody and of less feeding value.

Grass or other forage, when growing, contains much water, and after cutting must be left to dry in the sun and wind, a process which may at times be assisted by turning over or shaking up. In fine weather in the south of England grass is sufficiently dried in from two to four days to be stacked straight away. In the drying process the 75% of water usually present should be reduced to approximately 15% in the hay, and in wet or broken weather it is exceedingly difficult to do this. With a heavy crop or in damp weather grass may need turning in the swathe, raking up into "windrows" and then making up into cocks or "quiles," i.e., round bee-hive-like heaps, before it can be "carried." A properly made cock will stand bad weather for a week, as only the outside straws are weathered, and therefore the hay is kept fresh and green. Indeed, it is a good rule always to cock hay, for even in sunny weather undue exposure ends in bleaching, which is almost as detrimental to its quality as wet-weathering.

Introduction of Machinery.—In the last quarter of the 19th century the methods of haymaking were completely changed, and even some of the principles underlying its practices were revised. Generally speaking, before that time the only implements used were the scythe, the rake and the pitchfork; nowadays—with the exception of the pitchfork—these implements are seldom used, except where the work is carried on in a small way. Instead of the scythe, the mowing machine is employed, taking a swathe as wide as 5 or 6 feet. Some 10ac. per day can easily be mown thus by one man and a pair of horses. (See MOWING MACHINE.)

After the mown grass has lain in the swathe a day or two till it is partly dried, it is necessary to turn it over to dry the other side. This used to be done with the hand rake, and a band of men or women would advance across a field, each turning the hay by regular strokes at each step. This was the act of "hay-making" proper. The swathes as laid by the mowing machine lent themselves to this treatment in the old days when the swathe was only some 3 to 4ft. wide, but with the wide cut of the present day it becomes impracticable. If the hay is turned and "made" at all, the operation is now generally performed by a machine made for the purpose. There is a wide selection of "tedders" or "kickers" and "swathe-turners" on the market. (See TEDDER.)

It is a moot point, however, whether grass should be turned at all, or left to "make" as it falls from the mowing machine. In a dry sunny season and with a moderate crop it is only a waste of time and labour to turn it, for it will be cured quite well as it lies, especially if raked up into loose "windrows" a little before carrying to the stack. On the other hand, where the crop is

heavy (say over 2 tons per acre) or the climate is wet, turning will be necessary.

With heavy crops of clover, lucerne and similar forage crops turning may be an absolute necessity, because a thick swathe of a succulent crop will be difficult to dry or "make" excepting in hot sunny weather, but with ordinary meadow grass or with a mixture of "artificial" grasses, it may often be dispensed with. It must be remembered, however, that the process of turning breaks the stalks (thus letting out the albuminoid and saccharine juices) and should be avoided as far as possible in order to save both labour and the quality of the hay.

The Horse Rake.—One of the earlier mechanical inventions in connection with haymaking was the discovery of the horse rake. Before its introduction the hay, after making, had to be gathered up by the hand rake—a tedious and laborious process—but the introduction of this implement, whereby one horse and one man can do work formerly requiring six or eight men, marked a great advance. The horse rake is a framework on two wheels carrying hinged steel teeth placed *gin. apart*, so that their points slide along the ground below the hay. In work it gathers up the loose hay, and when full a tipping mechanism permits the emptying of the load.

The tipping is effected by pulling down a handle which sets a leverage device in motion, whereby the teeth are lifted up and the load of hay dropped below and left behind. On some rakes a clutch is worked by the driver's foot, and this put in action causes the ordinary forward revolving motion of the driving wheels to do the tipping.

The loads are tipped end to end as the rake passes and re-passes at the work, and thus the hay is left loose in long parallel rows on the field. Each row is termed a "windrow," the passage of the wind through the hay greatly aiding the drying and "making" thereof. When hay is in this form it may either be carried direct to the stack if sufficiently "made," or else put into the cocks to season a little longer. The original width of horse rakes was about 8ft., but nowadays they range up to 16 and 18 feet. The width should be suited to that of the swathe as left by the mower, and as the latter is now made to cut 5 and 6ft. wide, it is necessary to have a rake to cover two widths. The very wide rakes are only suitable for even, level land; those of less width must be used where the land has been laid down in ridge and furrow. As the swathes lie in long parallel rows, it is a great convenience in working for two to be taken in width at a time, so that the horse can walk in the space between.

The side-delivery rake, a development of the ordinary horse rake, is a useful implement, adapted for gathering and laying a quantity of hay in one continuous windrow. It is customary with this to go up the field throwing two swathes to one side, and then back down on the adjacent swathes, so that thus four are thrown into one central windrow. The implement consists of a frame carried on two wheels with shafts for a horse; across the frame are fixed travelling or revolving prongs of different varieties which pick up the hay off the ground and pass it along sideways across the line of travel, leaving it in one continuous line. Some makes of swathe-turners are designed to do this work as well as the turning of the hay.

Perhaps the greatest improvement of modern times is the method of carrying the hay from the field to the stack. An American invention known as the sweep rake was introduced by the writer into England in 1894, and now, in many modified forms, is in very general use in the Midlands and south of England, where the hay is carried from the cock, windrow or swathe straight to the stack. This implement consists of a wheeled framework fitted with long wooden iron-pointed teeth which slide along the ground; two horses are yoked to it—one at each side—the driver directing from a central seat behind the framework. When in use it is taken to the farther end of a row of cocks, a windrow, or even to a row of untouched swathes on the ground and walked forward. As it advances it scoops up a load, and when full it is drawn up to where the stack is being erected. In ordinary circumstances the sweep rake will pick up at a load two-thirds of an ordinary cart-load, but, where the hay is in

THE SIDE VIEW OF A HAY-MOWER
The cutting mechanism is an alternating knife, or sickle, with a separate blade to correspond to each finger on cutting bar

good order and it is swept down hill, a whole one-horse cart-load can be carried each time. The drier the hay the better will the sweep rake work, and if it is not working sweetly, but has a tendency to clog or make rolls of hay, it may be inferred that the latter is not in a condition fit for stacking. Where the loads must be taken through a gateway or a long distance to the stack, it is necessary to use carts or wagons, and the loading of these in the field out of the windrow is largely expedited by the use of the "loader," also an American invention of which many varieties are in the market. Generally speaking, it consists of a frame carrying a revolving web with tines or prongs. The implement is hitched on behind a cart or wagon, and as it moves forward the web picks the loose hay off the ground and delivers it on the top, where a man levels it with a pitchfork and builds it into a load ready to move to the stack. At the stack the most convenient method of transferring the hay from a cart, wagon or sweep rake is the elevator, a tall structure with a revolving web which carries teeth or spikes. The hay is thrown upon it in forkfuls at the bottom, a pony-gear causes the web to revolve, and the hay is carried in an almost continuous stream up the elevator and dropped over the top on to the stack. The whole implement is made to fold down, and is provided with wheels so that it can be moved from stack to stack. In the older forms there is a "hopper" or box at the bottom into which the hay is thrown to enable the teeth of the web to catch it, but in the modern forms there is no hopper, the web reaching down to the ground so that hay can be picked up from the ground level. Where the hay is brought to the stack on carts or wagons it can be unloaded by means of the horse fork. This is an adaptation of the principle of the ordinary crane; a central pole and jib are supported by guy ropes, and from the end of the jib a rope runs over a pulley. At the end of this rope is a "fork" formed of two sets of prongs which open and shut. This is lowered on to the load of hay, the prongs are forced into it, a horse pulls at the other end of the rope, and the prongs close and "grab" several hundredweight of hay which are swung up and dropped on the stack. In this way a large cart or wagon load is hoisted on to the stack in three or four "forkfuls." The horse fork is not suited for use with the sweep rake, however, because the hay is brought up to the stack in a loose flat heap without sufficient body for the fork to get hold of.

In Scotland and wet districts of England it is customary to "make" the hay as in the south, but it is then built up into little stacks in the field where it grew (ricks, pykes or tramp-cocks are names used for these in different districts), each containing about 10 to 15 hundredweight. These are made in the same way as the ordinary stack—one person on top building, another on the ground pitching up the hay—and are carefully roped and raked down. In these the hay gets a preliminary sweating or tempering while at the same time it is rendered safe from the weather, and, thus stored, it may remain for weeks before being carried to the big stacks at the homestead. The practice of putting up the hay into little ricks in the field has brought about the introduction of another set of implements for carrying these to the stackyard.

Various forms of rick-lifters are in use, the characteristic feature of which is a tipping platform on wheels to which a horse is attached between the shafts. The vehicle is backed against a rick, and a chain passed round the bottom of the latter, which is then pulled up the slant of the tipped platform by means of a small windlass. When the centre of the balance is passed, the platform carrying the rick tips back to the level, and the whole is thus loaded ready to move. Another variety of loader is formed of three shear-legs with block and tackle. These are placed over a rick, under which the grab-irons are passed, and the whole hauled up by a horse. When high enough a cart is backed in below, the rick lowered, and the load is ready to carry away.

Heating or Sweating.—When put into a stack the next stage in curing the hay begins—the heating or sweating. In the growing plants the tissues are composed of living cells containing protoplasm. This continues its life action as long as it gets

sufficient moisture and air. As life action involves the development of heat, the temperature in a confined space like a stack where the heat is not dissipated may rise to such a point that spontaneous combustion occurs. The chemical or physical reasons for this are not very well understood. The starch and sugar contents of the tissues are changed in part into alcohol. In the analogous process of making silage (*i.e.*, stacking wet green grass in a closed building) the alcohol develops into acetic acid, thus making "sour" silage. In a haystack the intermediate body, acetaldehyde, which is both inflammable and suffocating, is produced, leading to slow combustion and ignition. If the stack contains no air it does not heat, or if it has excess of air it is safe. The danger-point in a stack is the centre at about 6ft. from the ground; below this the weight of the hay itself squeezes out the air, and at the sides and top the heat is dissipated outwards. If a stack shows signs of overheating (a process that may take weeks or even months to develop) it can be saved by cutting a gap in the side of it with the hay knife, thus letting out the heat and fumes, and admitting fresh air to the centre. The essential point in haymaking is that the hay should be dried sufficiently to ensure the sweating process in the stack reaching no further than the stage of the formation of sugar. Good hay should come out green and with the odour of coumarin—to which is due the scent of newmown hay. Only part of a stack can ever attain to a perfect state: the tops, bottom and outsides are generally wasted by the weather after stacking, while there may be three or four intermediate qualities present. In some markets hay that has been sweated till it is brown in colour is desired, but for general purposes green hay is the best.

Hay often becomes musty when the weather during "making" has been too wet to allow of its getting sufficiently dry for stacking. Mustiness is caused by the growth of various moulds (*Penicillium Aspergillus*, etc.) on the damp stems, with the result that the hay when cut out for use is dusty and shows white streaks and spots. Such hay is inferior to that which has been overheated, and in practice it is found that a strong heating will prevent mouldiness by killing the fungi.

Heavy lush crops—especially those containing a large proportion of clover or other leguminous plants—are proportionately more difficult to "make" than light grassy ones. Thus, if one ton is taken as a fair yield off one acre, a two-ton crop will probably require four times as much work in curing as the smaller crop. In the treacherous climate of Great Britain hay is frequently spoiled because the weather does not hold good long enough to permit of its being properly "made." Consequently many experienced haymakers regard a moderate crop as the more profitable because it can be stacked in first-class condition, whereas a heavy crop forced by "high farming" is grown at a loss, owing to the weather waste and the heavier expense involved in securing it.

The making of the hay by drying out the grass is thus the most critical part of the work, and as far back as the '70s of last century trials were made in Essex of machinery whereby a blast of air heated in a furnace was blown through the stuff so as to dry it artificially. At the present time similar work is being done at Oxford, whereby, by building the stacks of half-dried hay with a hollow boss inside and an arrangement of pipes, hot air is forced through the material and thus the moisture is driven out in a cloud of vapour.

In handling or marketing out of the stack hay may be transported loose on a cart or wagon, but it is more usual to truss or bale it. A truss is a rectangular block cut out of the solid stack, usually about 3ft. long and 2ft. wide, and of a thickness sufficient to give a weight of 56 lb.; 36 of these constitute a "load" of 18 cwt.—the unit of sale in many markets. A truss is generally bound with two bands of twisted straw, but if it has to undergo much handling it is compressed in a hay-press and tied with two string bands. In some districts a baler is used: a square box with a compressible lid. The hay is tumbled in loose; the lid forced down by a leverage arrangement and the bale tied by three strings. It is usually made to weigh from 1 to 1½ hundredweight. The customs of different markets vary very much in their methods

of handling hay, and in the overseas hay trade the size and style of the trusses or bales are adapted for packing on ship-board.

(P. McC.)

The United States.—Hay is one of the four major field crops of the United States. In value it is usually outranked only by corn (maize) and cotton and in some years only by corn. In 1926 and 1927 it was the leading crop in total farm value in 16 important States. Hay is fundamental to the live stock industries of the entire country and is the chief feed when pasture grasses are not available. In the western States, alfalfa hay assumes the same relative importance in agriculture that corn possesses in the Mississippi valley States. In the United States, approximately 85% of all hay produced is fed to live stock in the counties where it is produced, while the remaining 15% is marketed, mostly as baled hay.

The principal kinds of hay grown in the United States, in the order of importance, are: timothy and its mixtures; alfalfa; wild hay; clover; miscellaneous cultivated grasses, such as blue-grass, reedtop, and Johnson grass; annual legumes, such as soy beans, cowpeas, and vetches; and grains, such as oats and wheat, cut prior to maturity. Timothy and its mixtures, including clover, are of chief importance in the north Atlantic and east north central States, where the relatively cool, humid climates are most favourable for their growth. Alfalfa ranks first in the western, south-western, and west north central States, where porous soils and relatively dry climates favour it. Wild hays grow in greatest quantity in the north central and south central prairie States, usually on stony, wet, slightly alkaline, sandy or gumbo soils unsuitable for cultivated crops. Annual legume hays are supreme in the east south central and south Atlantic States, where the soil and climatic conditions are generally not favourable for perennial hay crops such as timothy or alfalfa. Grain hay is produced in greatest quantity in the Pacific coast States, where, without irrigation, the foothill areas are too dry in the summer to support perennial hay crops.

The acreage of legume hays, principally alfalfa, clover and soy beans, has increased rapidly in the United States since 1900, wherever soil and climate are favourable. Legume hay has supplanted much grass hay characteristic of the early period of American agriculture. The rapidly increasing popularity of legume hays is due to the following facts: (1) They yield a greater tonnage of hay per acre than grass hays; (2) they improve the fertility of the soil because of their ability to assimilate atmospheric nitrogen and fix it in the soil in forms available to plant life, whereas grass hays deplete nitrogen in the soil; and (3) they have a much higher feed value than grass hays. Alfalfa is a more nearly perfect forage for animals than any other crop. Its protein content is two to three times higher than timothy; it contains other nutrients of great importance in the feeding of all forms of live stock; and it yields two to three times more hay per acre than timothy.

Hay-making in the United States is accomplished largely by machinery that has been designed to cut, rake, load, haul and store the hay with a minimum of hand labour. Mowers, drawn by two horses, and having sickle-bars 5 to 8 ft. in length, will cut down 10 to 15 ac. of standing hay in a working day of 10 hours. After cutting, the hay is allowed to wilt in the swath until the moisture has been reduced by evaporation from 70% or more to from 40 to 50%. It is then raked into windrows with either sulky or side-delivery rakes, drawn by two horses and having a capacity of 20 ac. per day. In very humid or very hot climates the windrowed hay is sometimes put up in cocks by hand labour and the curing completed in the cocks. On most hay farms no cocking is done, however, because of the expense of hand labour, and curing is accomplished in the windrows to that point at which the hay contains 25 to 30% of moisture and though still slightly tough is yet sufficiently dry to go into storage where the final curing and sweating processes take place. In making legume hays, the most practical method of curing is the use of the side-delivery rake that rolls the hay into loose cylindrical windrows through which winds pass easily to hasten drying and in which the majority of the leaves are preserved from bleaching and shattering. In humid climates the common practice is to load the cured hay on wagons

from the windrows by means of a hay-loader which picks up the hay and elevates it on an endless track to the wagon-rack where usually two men fork and tramp the hay into a compact load. The loads are then hauled to barns or sheds, where, by means of nets or a large fork, the hay is lifted with tackle, pulleys and horse-power into the mow. In arid and semi-arid climates the common practice is to move the cured hay from the windrows with sweep-rakes or low-built sleds to central knolls in the fields, where stacks of 15 to 200 tons are built. Stacking is accomplished by derricks or other stacking devices which utilize tackle, pulleys and horse-power to lift 400 to 800 lb. of hay at a time on to the stacks, where men with forks spread and tramp the hay into a symmetrical, sloping-sided stack that will shed light rains or snows.

Hay is commonly allowed to sweat and ferment slightly in the stacks or mows prior to feeding or shipping to market. Well-cured and sweated hay contains 10 to 14% of moisture, and in this condition can be shipped long distances without damage unless it becomes wet in loading or transit. Hay for market shipment is compressed into bales of various kinds and sizes weighing from 60 to 300 lb. each, and tied with from two to five wires to hold the compressed hay in a compact mass. The presses which make the bales are usually operated by engine power and are portable, so that they may be transported from one field or one farm to another. In the most common type of press, loose hay is pitched into a hopper, whence it is drawn into a chamber in which a plunger is forced back and forth to pack the hay into "flakes" within the four walls of the chamber. When a sufficient number of these flakes have been pressed together to form a bale of standard size, several wires are passed around the compressed mass of hay and the ends tied. The bale is then released from the press and the process of compressing and tying is repeated. The capacity of hay presses ranges from 15 to 60 tons per day of 10 working hours according to the size and power of the press, the size of the crew and the availability of the loose hay. In some regions hay baling is done in the fields, the hay being fed into the press directly from the windrows or smaller presses drawn by horses from one haycock to another. In other regions the presses are placed in barn driveways or beside stacks and the loose hay is pitched into the press from its place of storage.

MARKETING AND DISTRIBUTION

The marketing and distribution of baled hay in the United States is a large business. From 1921 to 1927, nearly 600,000 car lots of baled hay were loaded annually. Other large but undetermined quantities are transported by trucks directly from producer to consumer. The chief hay markets in the United States are Kansas City, Los Angeles, Chicago, San Francisco, Omaha, St. Louis, Cincinnati, Pittsburgh, New York, Boston, Seattle, St. Paul and Minneapolis, Denver, Memphis, New Orleans, Houston, Fort Worth, Atlanta, Birmingham and Jacksonville. Before 1910 the most important market demand for baled hay arose from the feeders of horses and mules in the cities, mines, logging and construction camps. With the advent of automobiles, motor trucks and tractors the horses in cities decreased approximately 70% from 1910 to 1925, and the market demand, therefore, for timothy and other grass hays has been greatly curtailed. The reduction in the demand for baled timothy and other grass hays for horse feeding has been offset, however, by the increased demand from the expanding dairy industry of the country for baled legume hays, especially alfalfa and clover. Specialized dairy management depends on specialized hay production for large quantities of legume forage, and thus the hay marketing business has become one largely associated with dairying. Other important sources of regular demand are the stock-yards at meat-packing plants and railway division points, the U.S. Army, and the specialized agricultural industries, such as cotton and fruit farming.

Standards of quality for hay have been formulated by the U.S. department of agriculture. These standards provide three numerical grades for all kinds of hay based on definite colour and foreign material requirements. The grades for alfalfa hay also have a leafiness requirement. The grade or quality of hay varies largely according to the varying amounts of these factors. In addition to

the numerical grades a sample grade is provided for hay that is unsound, badly weathered, badly overripe or badly stained, and that contains excessive amounts of foreign material or otherwise fails to meet the requirements of the numerical grades. Some of the complete grade designations in these standards are as follows: U.S. No. 2 Timothy, U.S. No. 1 Alfalfa, U.S. No. 3 Timothy Light Clover Mixed, U.S. No. 2 Alfalfa Light Grass Mixed, U.S. No. 1 Upland Prairie, U.S. Sample Grade Clover (musty), and U.S. Sample Grade Timothy (badly overripe). By means of these standards quality specifications may be written into a hay contract as well as specifications of weight, price, time and place of delivery, etc. Official inspectors are maintained at important shipping points and receiving markets to inspect lots of hay and to issue certificates of quality and condition, which may be used by shippers, dealers and others in marketing hay to evidence the fulfillment of hay contracts as to quality. (E. C. P.)

HAYASHI, TADASU, COUNT (1850-1913), Japanese statesman, was born in Tokyo (then Yedo), and was one of the first students sent by the Tokugawa government to study in England. He returned on the eve of the abolition of the Shogunate, and followed Enomoto (*q.v.*) when the latter, sailing with the Tokugawa fleet to Yezo, attempted to establish a republic there in defiance of the newly organized government of the emperor. Thrown into prison on account of this affair, Hayashi did not obtain office until 1871. He then rose rapidly, until, after a long period of service as vice-minister of foreign affairs, he was appointed to represent his country first in Peking, then in St. Petersburg and finally in London, where he acted an important part in negotiating the first Anglo-Japanese alliance, for which he received the title of viscount. He remained in London throughout the Russo-Japanese War, and was the first Japanese ambassador at the court of St. James's after the war. Returning to Tokyo in 1906 to take the portfolio of foreign affairs, he remained in office until the resignation of the Saionji cabinet in 1908. He was raised to the rank of count for services during the Russo-Japanese War, and in connection with the second Anglo-Japanese Alliance of 1905. He died at Tokyo on July 10, 1913.

HAYDEN, FERDINAND VANDEVEER (1829-1887), American geologist, was born at Westfield, Mass., on Sept. 7, 1829. He graduated from Oberlin college in 1850 and from the Albany medical college in 1853, where he attracted the notice of Prof. James Hall, State geologist of New York, through whose influence he was induced to join in an exploration of Nebraska. In 1856 he was engaged under the U.S. Government, and commenced a series of investigations of the western Territories, one result of which was his *Geological Report of the Exploration of the Yellowstone and Missouri Rivers in 1859-60* (1869). During the Civil War he was actively employed as an army surgeon. In 1867 he was appointed geologist-in-charge of the U.S. geological and geographical survey of the territories, and from his 12 years of labour there resulted a most valuable series of volumes in all branches of natural history and economic science; and he issued in 1877 his *Geological and Geographical Atlas of Colorado*. Upon the reorganization and establishment of the U.S. geological survey in 1879 he acted for seven years as one of the geologists. He died at Philadelphia on Dec. 22, 1887.

His other publications were: *Sun Pictures of Rocky Mountain Scenery* (1870); *The Yellowstone National Park*, illustrated by chromolithographic reproductions of water-colour sketches by Thomas Moran (1876); *The Great West: its Attractions and Resources* (1880). With F. B. Meek, he wrote (*Smithsonian Institution Contributions*, vol. 14, Art. 4) "Palaeontology of the Upper Missouri, pt. I., Invertebrate." His valuable notes on Indian dialects are in *The Transactions of the American Philosophical Society* (1862), in *The American Journal of Science* (1862) and in *The Proceedings of the American Philosophical Society* (1869). With A. R. C. Selwyn he wrote *North America* (1883) for Stanford's *Compendium*.

HAYDN, FRANZ JOSEPH (1732-1809), Austrian composer, was born on March 31, 1732, at Rohrau (Trstnik), a village on the borders of Lower Austria and Hungary. There is sufficient evidence that his family was of Croatian stock: a fact which throws light upon the distinctively Slavonic character of much of his music. He received the first rudiments of education from his father, a wheelwright with 12 children, and at an early age

evinced a decided musical talent. This attracted the attention of a distant relative named Johann Mathias Frankh, who was schoolmaster in the neighbouring town of Hainburg, and who, in 1738, took the child and for the next two years trained him as a chorister. In 1740, on the recommendation of the Dean of Hainburg, Haydn obtained a place in the cathedral choir of St. Stephen's, Vienna, where he took the solo-part in the services and received, at the choir school, some further instruction on the violin and the harpsichord. In 1749 his voice broke, and the director, Georg von Reutter, took the occasion of a boyish escapade to turn him into the streets. A few friends lent him money and found him pupils, and in this way he was enabled to enter upon a rigorous course of study (he is said to have worked for 16 hours a day), partly devoted to Fux's treatise on counterpoint, partly to the "Friedrich" and "Württemberg" sonatas of C. P. E. Bach, from which he gained his earliest acquaintance with the principles of musical structure. The first fruits of his work were a comic opera, *Der neue krumme Teufel*, and a *Mass* in F major (both written in 1751), the former of which was produced with success. About the same time he made the acquaintance of Metastasio, who was lodging in the same house, and Porpora, who gave him instruction in singing and in the Italian language.

The turning-point in his career came in 1755, when he accepted an invitation to the country-house of Freiherr von Fürnberg, an accomplished amateur who was in the habit of collecting parties of musicians for the performance of chamber-works. Here Haydn wrote, in rapid succession, 18 divertimentos which include his first symphony and his first quartet; the two earliest examples of the forms with which his name is most closely associated. Thenceforward his prospects improved. On his return to Vienna in 1756 he became famous as teacher and composer, in 1759 he was appointed conductor to the private band of Count Morzin, for whom he wrote several orchestral works (including a symphony in D major erroneously called his first), and in 1760 he was promoted to the sub-directorship of Prince Paul Esterhazy's Kapelle, at that time the best in Austria. During the tenure of his appointment with Count Morzin he married the daughter of a Viennese hairdresser named Keller, who had befriended him in his days of poverty, but the marriage turned out ill and he was soon separated from his wife. From 1760 to 1790 he remained with the Esterhazys, principally at their country-seats of Esterházy and Eisenstadt, with occasional visits to Vienna in the winter. In 1762 Prince Paul Esterhazy died and was succeeded by his brother Nicholas, surnamed the Magnificent, who increased Haydn's salary, showed him every mark of favour, and, on the death of Werner in 1766, appointed him Oberkapellmeister. With the encouragement of a discriminating patron, a small but excellent orchestra and a free hand, Haydn made the most of his opportunity and produced a continuous stream of compositions in every known musical form. To this period belong five *Masses*, a dozen operas, over 30 clavier-sonatas, over 40 quartets, over 100 orchestral symphonies and overtures, a *Stabat Mater*, a set of interludes for the service of the Seven Words, an oratorio, *Tobias*, written for the Tonkünstler-Societät of Vienna, and a vast number of concertos, divertimentos and smaller pieces, among which were no fewer than 175 for Prince Nicholas' favourite instrument, the baryton.

Meanwhile his reputation was spreading throughout Europe. A Viennese notice of his appointment as Oberkapellmeister spoke of him as "the darling of our nation"; his works were reprinted or performed in every capital from Madrid to St. Petersburg—(Leningrad). He received commissions from the cathedral of Cadiz, from the grand duke Paul, from the king of Prussia, from the directors of the Concerts Spirituels at Paris; beside his transactions with Breitkopf and Härtel, and with La Chevardière, he sold to one English firm the copyright of no fewer than 129 compositions. But the most important fact of biography during these 30 years was his friendship with Mozart, whose acquaintance he made at Vienna in the winter of 1781-82. There can have been little personal intercourse between them, for Haydn was rarely in the capital, and Mozart seems never to have visited Eisenstadt; but the cordiality of their relations and the mutual influence which

they exercised upon one another are of the highest moment in the history of 18th-century music. "It was from Haydn that I first learned to write a quartet," said Mozart; it was from Mozart that Haydn learned the richer style and the fuller mastery of orchestral effect by which his later symphonies are distinguished.

In 1790 Prince Nicholas Esterhazy died and the Kapelle was disbanded. Haydn, thus released from his official duties, forthwith accepted a commission from Salomon, the London concert-director, to write and conduct six symphonies for the concerts in the Hanover square rooms. He arrived in England at the beginning of 1791 and was welcomed with the greatest enthusiasm, receiving among other honours the degree of D.Mus. from the University of Oxford. In June 1792 he returned home, and, breaking his journey at Bonn, was presented with a cantata by Beethoven, then aged 22, whom he invited to come to Vienna as his pupil. The lessons, which were not very successful, lasted for about a year, and were then interrupted by Haydn's second visit to England (Jan. 1794 to July 1795), where he produced the last six of his Salomon symphonies. From 1795 onward he resided in the Mariahilf suburb of Vienna, and there wrote his last eight *Masses*, the last and finest of his chamber works, the Austrian national anthem (1797), the *Creation* (1799) and the *Seasons* (1801). He died on March 27, 1809, aged 77.

Haydn's place in musical history is best determined by his instrumental compositions. His operas, for all their daintiness and melody, no longer hold the stage; the *Masses* in which he "praised God with a cheerful heart" have been condemned by the severer decorum of our own day; of his oratorios the *Creation* alone survives. In all these his work belongs mainly to the style and idiom of a bygone generation: they are monuments, not landmarks, and their beauty and invention seem rather to close an epoch than to inaugurate its successor. Even the naïf pictorial suggestion, of which free use is made in the *Creation* and in the *Seasons*, is closer to the manner of Handel than to that of the 19th century: it is less the precursor of romance than the descendant of an earlier realism. But as the first great master of the quartet and the symphony his claim is incontestable. The quartets in particular exhibit a wider range and variety of structural invention than those of any other composer except Beethoven. Again it is here that we can most readily trace the important changes which he wrought in melodic idiom. Before his time instrumental music was chiefly written for the *Paradiesen-saal*, and its melody often sacrificed vitality of idea to a ceremonial courtliness of phrase. Haydn broke through this convention by frankly introducing his native folk-music, and by writing many of his own tunes in the same direct, vigorous and simple style. The innovation was at first received with some disfavour; critics accustomed to polite formalism censured it as extravagant and undignified; but the freshness and beauty of its melody soon silenced all opposition, and did more than anything else throughout the 18th century to establish the principle of nationalism in musical art. The actual employment of Croatian folk-tunes may be illustrated from the string quartets op. 17, No. 1; op. 33, No. 3; op. 50, No. 1; op. 77, No. 1, and the Salomon symphonies in D and E^b, while there is hardly an instrumental composition of Haydn's in which his own melodies do not show some traces of the same influence.

In the development of instrumental polyphony Haydn's work was almost as important as that of Mozart. Having at his disposal a band of picked virtuosi he could produce effects as different from the tentative experiments of C. P. E. Bach as these were from the orchestral platitudes of Reutter or Hasse. His symphony *Le Midi* (written in 1761) already shows a remarkable freedom and independence in the handling of orchestral forces, and further stages of advance were reached in the oratorio of *Tobias*, in the Paris and Salomon symphonies, and above all in the *Creation*; which turns to good account some of the debt which he owed to his younger contemporary. The importance of this lies not only in a greater richness of musical colour, but in the effect which it produced on the actual substance and texture of composition. The polyphony of Beethoven was unquestionably influenced by it and, even in his latest sonatas and quartets, may be regarded as its logical outcome.

The compositions of Haydn include 104 symphonies, 16 overtures, 76 quartets, 68 trios, 54 sonatas, 31 concertos and a large number of divertimentos, cassations and other instrumental pieces; 24 operas and dramatic pieces, 16 *Masses*, a *Stabat Mater*, interludes for the "Seven Words," three oratorios, two Te Deums and many smaller pieces for the Church, over 30 songs, over 50 canons and arrangements of Scottish and Welsh national melodies.

His younger brother, JOHANN MICHAEL HAYDN (1737-1806), was also a chorister at St. Stephen's, and shortly after leaving the choir-school was appointed Kapellmeister at Grosswardein (1755) and at Salzburg (1762). The latter office he held for 43 years, during which time he wrote over 360 compositions for the Church and much instrumental music, which, though unequal, deserves more consideration than it has received. He was the intimate friend of Mozart, who had a high opinion of his genius, and the teacher of C. M. von Weber. His most important works were the *Missa hispanica*, which he exchanged for his diploma at Stockholm, a *Mass* in D minor, a *Lauda Sion*, a set of graduals, 42 of which are reprinted in Diabelli's *Ecclesiasticon*, three symphonies (1785), and a string quintet in C major which has been erroneously attributed to Joseph Haydn.

Another brother, JOHANN EVANGELIST HAYDN (1743-1805), gained some reputation as a tenor vocalist, and was for many years a member of Prince Esterhazy's Kapelle.

Hadow, *A Croatian Composer* (1897). (W. H. H.)

HAYDN, BENJAMIN ROBERT (1786-1846), English historical painter and writer, was born at Plymouth on Jan. 26, 1786. His mother was the daughter of Benjamin Cobley, rector of Dodbrook, Devon. His father, a prosperous printer, stationer and publisher, was a man of literary taste. Haydn became a student at the Royal Academy in 1804. In 1807 he exhibited, for the first time "The Repose in Egypt." In 1809 he finished his well-known picture of "Dentatus." He had great ambitions which involved him in great difficulties, and in a quarrel with the Royal Academy. "The Judgment of Solomon" (1814) gained him a prize from the British Institution, and the freedom of the borough of Plymouth. Haydn then joined his friend Wilkie in a trip to Paris; he studied at the Louvre; and on his return to England produced his "Christ's Entry into Jerusalem," which afterwards formed the nucleus of the American gallery of painting, erected by his cousin, John Haviland of Philadelphia.

As a result of his pecuniary difficulties in 1823 Haydn was lodged in the King's Bench, where he received consoling letters from the first men of the day. Whilst a prisoner he drew up a petition to parliament in favour of the appointment of "a committee to inquire into the state of encouragement of historical painting," which was presented by Brougham. He also, during a second imprisonment in 1827, produced the picture of the "Mock Election," the idea of which had been suggested by an incident that happened in the prison. The king (George IV.) gave him £500 for this work. Among Haydn's other pictures were "Punch" (1829), "Lazarus" (1821-23) in the possession of the Tate gallery, and the "Meeting of the Anti-Slavery Society," in the National Portrait Gallery. When the competition took place at Westminster Hall, Haydn sent two cartoons, "The Curse of Adam" and "Edward the Black Prince," but he was not allowed a prize for either. The artist's difficulties increased to such an

extent that, whilst employed on his last effort, "Alfred and the Trial by Jury," overcome by debt and disappointment he wrote "Stretch me no longer on this rough world," and put an end to his existence with a pistol-shot, on June 22, 1846.

See: Haydon's *Autobiography and Journals* (1847), of which a new edition (2 vols.) was published, with introd. by Aldous Huxley, in 1926; Tom Taylor, *Life of B. R. Haydon* (1853); F. W. Haydon, *Correspondence and Table Talk* (1876); Haydon published a pamphlet on Fresco and Oil Painting (1842) and *Lectures on Painting and Design* (1847); he was also the author of the article on PAINTING in the 7th edition of the *Encyclopædia Britannica*.

HAYES, PATRICK JOSEPH (1867–), American cardinal, was born in New York city, Nov. 20, 1867. He graduated from Manhattan college in 1888, continued his studies at St. Joseph's seminary in Troy (N.Y.), and was there ordained priest in 1892. After a graduate course at the Catholic University of Washington, he became curate of St. Gabriel's parish in New York city. In 1903 Archbishop Farley of New York, who had been his parish priest, appointed him his secretary and chancellor. In the same year Cathedral college was opened, and he became its first president, an office which he held for 11 years.

In 1914 he was consecrated titular bishop of Tagaste and bishop auxiliary of New York. In the following year he was made rector of St. Stephen's church, and on Nov. 24, 1917, was appointed Catholic chaplain bishop for the U.S. army and navy, in which capacity he travelled extensively, appointing chaplains to the various camps. He was made archbishop of New York in 1919. Early in 1924 he was summoned to Rome by Pope Pius XI. and was made a cardinal at a consistory held on March 25, having been assigned the church of Santa Maria in Via as his titular church.

See J. J. Walsh, *Our American Cardinals* (1926).

HAYES, ROLAND (1889–), American negro tenor was born in Georgia; soon after his mother, an ex-slave, moved with her two sons to Chattanooga, Tenn. When 16 years old Hayes was moulder in a stove factory, and singing in a church choir "jus' 'cause he liked to." He chanced to be heard by W. Arthur Calhoun, also a negro, and a music student at Oberlin who after much persuasion induced him to receive musical instruction and later to enter Fisk university. As one of the Fisk Jubilee singers he appeared in Boston. Here he remained and entered upon a systematic musical education under the instruction of Arthur Hubbard. His first concert was given Nov. 15, 1917, at Symphony hall, Boston, and soon after he appeared with the Boston Symphony orchestra. In 1920 he went to London and sang by royal command at Buckingham palace and afterward at Wigmore hall. In 1923 he gave concerts in Berlin and Vienna. The same year he appeared under Pierné with the Colonne orchestra, winning the praise of Paris where his compelling interpretation of negro spirituals, which form a part of all his programmes, came as a strange and wonderful revelation. Since 1920 he has divided his time in annual tours between the United States and Europe and few singers have won wider attention. To a lyric voice of great sweetness, purity and range he adds a scholarly understanding of music. In 1924 he was made Spingarn medallist. A bronze by Renée Vantier presents him while singing the negro spiritual "Steal away to Jesus."

HAYES, RUTHERFORD BIRCHARD (1822–1893), 19th president of the United States, 1877–1881, was born in Delaware, O., on Oct. 4, 1822. His ancestry was English and Scotch, his people having first settled in America in New England. He attended an academy at Norwalk, O., and later went to a school in Middletown, Conn. In 1842 he graduated from Kenyon college, O., and in 1845 from the Harvard Law school. The same year he was admitted to the bar, and began to practice at Lower Sandusky (now Fremont), O. Three years later he removed to Cincinnati. From 1858–61 he was city solicitor there. In 1861 he became major of a regiment of volunteers, the 23rd Ohio Infantry, and in July of that year was sent to western Virginia, for active service. He served throughout the Civil War, and was severely wounded at South mountain. By successive promotions he became a brigadier-general of volunteers, and by brevet a major-general of volunteers. In 1864 he was elected a member of Congress on the Republican ticket, and

again in 1866. In the National legislature he supported his party's programme of reconstruction. In 1868 he became governor of Ohio, serving until 1872. In 1875 he was again elected governor after a campaign wherein the Republicans advocated the resumption of specie payment, and the Democrats an increase of fiat paper money. The "sound money" campaign in Ohio attracted national attention, and in 1876 Hayes received the Republican nomination for the presidency over James G. Blaine. Samuel J. Tilden was the Democratic candidate. He had a reputation as a reformer, having destroyed the "Tweed ring" in New York and been prominently engaged in other public work. The strength of the Democratic candidate, together with the scandals of Grant's administrations which had tended to discredit the Republican party, resulted in a close election, which depended upon the contested returns from South Carolina, Florida, Oregon and Louisiana. Partisans on both sides were much excited. It was agreed, however, to refer the contested returns to an electoral commission created by act of Congress. The commission voting eight to seven decided all of the contested returns in favor of the Republicans, and Hayes was declared elected on March 2, 1877.

The administration of President Hayes is notable principally for the pacification policy adopted by it with respect to the Southern States. The Federal troops, which had since the war been stationed in the Southern capitals, were withdrawn, thereby bringing about the end of the "carpet-bag governments" conducted often by unprincipled politicians from the North. This action brought Hayes into sharp conflict with many of the political leaders of his party. It, however, made more rapid the slow recovery of the South from the effects of the war, and was highly beneficial to the nation. In his endeavours to bring about reforms in the civil service, and in his advocacy of the establishment of a civil service commission, Hayes also met with the opposition and disapproval of the politicians of his party. The New York faction, under the leadership of Roscoe Conkling, particularly resented his measures in endeavouring to divorce the service from politics. Another notable accomplishment of the Hayes administration was the provision for the resumption of specie payments on Jan. 1, 1879. Prior to this time Hayes vetoed a bill, known as the Bland-Allison bill, providing that a silver dollar should be coined of the weight of 412½ gr. to become full legal tender for all debts and dues, public and private, except where otherwise expressly stipulated in the contract, but the measure passed over his veto. He was at all times a sincere advocate of sound money.

Hayes has generally been considered an able executive, thoroughly honest and sincerely devoted to the interests of the people and the country generally. Upon his retirement from the Presidency, he returned to his home at Fremont, engaging actively in various philanthropic enterprises. It was there that he died, after a short illness, on Jan. 17, 1893.

HAY FEVER, HAY ASTHMA or SUMMER CATARRH, a catarrhal affection of the mucous membrane of the upper respiratory tract, due to the action of the pollen of certain grasses. It is often associated with asthmatic attacks. Hay fever is an example of hyper-sensitiveness to protein (see ANAPHYLAXIS) met with in certain individuals. The complaint has been investigated by Professor W. P. Dunbar of Hamburg, who has shown that it is due to the pollens of certain grasses (notably rye) and plants, and that the severity of the attack is directly proportional to the amount of pollen in the air. He has isolated an albuminoid poison which, when applied to the nose of a susceptible individual, causes an attack, while there is no result in the case of a normal person. By injecting the poison into animals he has obtained an antiserum, which is capable of aborting an attack of hay fever. The symptoms are those commonly experienced in the case of a severe cold, consisting of headache, violent sneezing, and watery discharge from the nostrils and eyes, together with a hard dry cough and occasionally severe asthmatic parox-

ysms. The period of liability to infection naturally coincides with the pollen season.

The radical treatment is to avoid vegetation. Local treatment consisting of thorough destruction of the sensitive area of the mucous membrane of the nose often produces good results. There are various drugs, the best of which are cocaine and the extract of the suprarenal body, which, when applied to the nose, are sometimes effectual; in practice, however, it is found that larger and larger doses are required, and that sooner or later they afford no relief. The same remarks apply to a number of patent specifics, of which the principal constituent is one of the above drugs. An additional and stronger objection to the use of cocaine is that a "habit" is often contracted, with the most disastrous results. Finally Dunbar's serum may be applied to the nose and eyes on rising, and on the slightest suggestion of irritation during the day, or doses may be injected subcutaneously.

HAYLEY, WILLIAM (1745-1820), English writer, the friend and biographer of William Cowper, was born at Chichester and educated at Eton and Trinity Hall, Cambridge. His private means enabled him to live on his patrimonial estate at Earham, Sussex, and he retired there in 1774. Hayley won contemporary fame by his poetical *Essays and Epistles* addressed to various distinguished men. On Thomas Warton's death in 1790 he was offered the laureateship, which he refused. In 1792, while writing the *Life of Milton* (1794), Hayley made Cowper's acquaintance. A warm friendship sprang up between the two which lasted till Cowper's death in 1800. After Hayley had moved in 1800 to his "marine hermitage" at Felpham, Sussex, William Blake settled near him for three years to engrave the illustrations for the *Life of Cowper*. This, Hayley's best known work, was published in 1803-04 (Chichester) in 3 vols. In 1805 he published *Ballads founded on Anecdotes of Animals* (Chichester), with illustrations by Blake, and in 1809 *The Life of Romney*. For the last 12 years of his life Hayley received an allowance for writing his *Memoirs*. He died at Felpham on Nov. 12, 1820.

Hayley's *Poetical Works* were published in 3 vols. (1785); his *Poems and Plays* in 6 vols. (1788). See *Memoirs . . . of William Hayley, . . . and Memoirs of his son T. A. Hayley*, ed. John Johnson (2 vols., 1823) (containing many of Hayley's letters); an article on these memoirs by Robert Southey in the *Quarterly Review*, vol. xxxi, 1825; *The Correspondence of William Cowper*, arranged by Thomas Wright (vol. iv., 1904), containing many letters to Hayley.

HAYM, RUDOLF (1821-1901), German publicist and philosopher, was born at Grünberg, Silesia, on Oct. 5, 1821, and died at St. Anton (Arlberg) on Aug. 27, 1901. He studied philosophy and theology at Halle and Berlin, and was a member of the National Assembly at Frankfurt in 1848. From 1851 he lectured in literature and philosophy at the University of Halle. His writings are biographical and critical, devoted mainly to modern German philosophy and literature. In 1870 he published a masterly history of the Romantic school. His biographies of W. von Humboldt (1856), Hegel (1857), Schopenhauer (1864), Herder (1877-85) and Max Duncker (1890) ably portray the relation of these thinkers to the thought of their day. In 1902 appeared his *Erinnerungen aus meinem Leben*, in 1902 *Philosophische Abhandlungen*, and in 1903 *Gesammelte Aufsätze*.

HAYNAU, JULIUS JACOB (1786-1853), Austrian general, was the natural son of the landgrave—afterwards elector—of Hesse-Cassel, William IX. He entered the Austrian army as an infantry officer in 1801, saw much service in the Napoleonic wars, and between 1815 and 1847 rose to the rank of field marshal lieutenant. A capable officer, but of violent temper and fanatical hatred of revolutionary movements, he was employed against the Italian revolutionaries in 1848, and became notorious for the severity with which he repressed and punished, not without provocation, a rising in Brescia. Appointed next to command in Hungary, he was successful in the field, but was again accused of brutality. In London he was attacked and beaten by Messrs. Barclay and Perkins' draymen when visiting the brewery, and was saved from mob violence in Brussels with difficulty. He died on March 14, 1853.

See R. v. Schönhals, *Biographie des K. K. Feldzeugmeisters Julius Freiherrn von Haynau* (Vienna, 1875).

HAYNAU, a town in the Prussian province of Silesia, on the Schnelle Deichsa and the railway from Breslau to Dresden, 12 m. N.W. of Liegnitz. Pop. (1925) 10,200. It has manufactures of gloves, patent leather, paper, metal ware and artificial manures and a considerable trade in cereals.

HAYNE, ROBERT YOUNG (1791-1839), American political leader, born in St. Paul's parish, Colleton district, S.C., on Nov. 10, 1791. He studied law in the office of Langdon Cheves (1776-1857) in Charleston, S.C., and in Nov. 1812 was admitted to the bar there, soon obtaining a large practice. For a short time during the war of 1812 against Great Britain, he was captain in a South Carolina regiment. He was a member of the lower house of the State legislature from 1814 to 1818, serving as speaker in the latter year; was attorney general of the State from 1818 to 1822, and in 1823 was elected, as a Democrat, to the U.S. Senate. Here he was conspicuous as an ardent free-trader and an uncompromising advocate of "States' rights," opposed the protectionist tariff bills of 1824 and 1828, and consistently upheld the doctrine that slavery was a domestic institution and should be dealt with only by the individual States. In one of his speeches opposing the sending by the United States of representatives to the Panama Congress, he said, "The moment the Federal Government shall make the unhallowed attempt to interfere with the domestic concerns of the States, those States will consider themselves driven from the Union." Hayne is best remembered, however, for his great debate with Daniel Webster (*q.v.*) in Jan. 1830. The debate arose over the so-called "Foote's resolution," introduced by Senator Samuel A. Foote (1780-1846) of Connecticut, calling for the restriction of the sale of public lands to those already in the market, but was concerned primarily with the relation to one another and the respective powers of the Federal Government and the individual States, Hayne contending that the Constitution was essentially a compact between the States, and the National Government and the States, and that any State might, at will, nullify any Federal law which it considered to be in contravention of that compact. He vigorously opposed the tariff of 1832, was a member of the South Carolina Nullification Convention of Nov. 1832, and reported the ordinance of nullification passed by that body. Resigning from the Senate, he was governor of the State in 1832-34, and as such took a strong stand against President Jackson, though he was more conservative than many of the nullificationists in the State. He was intendant (mayor) of Charleston, S.C., 1835-37, and was president of the Louisville, Cincinnati and Charleston railway 1837-39. He died at Asheville, N.C., on Sept. 24, 1839. His son, Paul Hamilton Hayne (1830-1886), was a poet of some distinction, and in 1878 published a life of his father.

See Theodore D. Jervay, *Robert Y. Hayne and his Times* (1909); and John Bomar Cleveland, *Controversy Between John C. Calhoun and Robert Young Hayne* (1913).

HAYTER, SIR GEORGE (1792-1871), English painter, was born in London, and in his early youth went to sea. He afterwards studied in the Royal Academy, became a miniature painter, and was appointed in 1816 miniaturist to the princess Charlotte. He passed some years in Italy, more especially in Rome, between 1816 and 1831. After his return to London he executed many portraits of the royal family, and was appointed principal painter to Queen Victoria and teacher of drawing to the princesses. In 1842 he was knighted. He painted various works on a large scale of a public and semi-historical character, but essentially works of portraiture, such as "The Trial of Queen Caroline" (189 likenesses), "The Meeting of the First Reformed Parliament," now in the National Portrait Gallery, "Queen Victoria taking the Coronation Oath" (accounted his finest production), "The Marriage of the Queen" and the "Trial of Lord William Russell."

HAYTON (HAITHON, HETHUM), king of Little Armenia or Cilicia from 1224 to 1269, traveller in western and central Asia, Mongolia, etc., was the son of Constantine Rupen, and became heir to the throne of Lesser Armenia by his marriage with Isabella, daughter and only child of Leo II. After a reign of 45 years he abdicated (1269) in favour of his son Leo III., became a monk

and died in 1271. Before his accession he had been "constable," or head of the Armenian army, and "bailiff" of the realm. Throughout his reign he followed the policy of friendship and alliance with the overwhelming power of the Mongols. In about 1248 he sent his brother Sempad, who was now constable in his place, on a mission to Kuyuk Khan, the supreme Mongol emperor. Sempad was well received and returned home in 1250, bringing letters from Kuyuk. After Mangu's accession in 1251, Batu (the most powerful of the Mongol princes and generals, and the conqueror—in name at least—of eastern Europe, now commanding on the line of the Volga) summoned Hayton to the court of the new grand khan. Carefully disguised, so as to pass safely through the Turkish States in the interior of eastern Asia Minor (where he was hated as an ally of the Mongols against Islam), Hayton made his way to Kars, the central Mongol camp in Great Armenia. He reported himself, and was permitted to remain some time in the Ararat region, at the foot of Mt. Alagoz, near the metropolitan church of Echmiadzin. Being joined by his suite, especially the clerical diplomatists Basil the Priest, and James the Abbot, Hayton next passed through eastern Caucasia, threading the pass of the Iron Gates of Derbent, and so reached the camp of Batu on the Volga, where he was cordially welcomed. Thence he set out (May 13, 1254) on the "very long road beyond the Caspian sea" to the residence of Mangu at or near Karakorum, south of Lake Baikal. After passing the Ural river, we only hear of his arrival at Or, probably the present Ili province, east of Balkhash, and of his reaching the Irtysh, entering the Naiman country, and passing through "Karakhitai" (apparently the capital of the ruined Karakhitai empire is intended, a place perhaps situated on the Chu, mentioned out of its proper place in Hayton's record). On Sept. 13 the travellers entered Mongolia, and on the 14th (?) were received by Mangu. Here the king remained till Nov. 1, when he left with diplomas, seals and letters of enfranchisement which promised great things for the Armenian State, church and people. His return journey was by very unusual and interesting routes—through the Urumtsi region, the basin of "the sea of milk," Lake Sairam, the valley of the Ili, the neighbourhood of Kulja, and so over mountains, which probably answer to certain outliers of the Alexander range, to Talas near the present Aulie Ata, midway between the Syr Daria and the Chu. Here he met and conferred with Hulagu Khan, Mangu's brother, the future conqueror of Bagdad; probably Hayton was expected to aid in the coming forward movement of the Mongol armies against the Muslim world. From Talas Hayton made a detour to the north-west to meet another Mongol prince, Sartach the son of Batu; after which he ascended the valley of the Syr Daria, crossed into Trans-Oxiana, visited Samarkand and Bokhara, and passed the Oxus apparently near Charjui. By way of Merv and Sarakhs he then entered Khorasan and traversed north Persia, passing through Rai near Tehran, Kazvin and Tabriz, and so returning to the camp of Bachu in Armenia, now at Sisian near Lake Gokcha (July 1255). Thanks to his powerful friends, Hayton's journey was unusually rapid. Eight months after quitting Mangu's horde, he was back in Great Armenia. The narrative of this journey, which was written by a member of the king's suite, one Kirakos of Gandsak (the modern Elizavetpol), concludes with some interesting references to Buddhist tenets, to Chinese habits, to various monstrous races and to certain "women endowed with reason" dwelling "beyond Cathay." It also gives some notes, compounded of truth and legend, on the wild tribes and animals of the Gobi and adjoining regions.

The record drawn up by Kirakos Gandsaketsi was in Armenian. A ms. of his, dated 1616, was found in the Sanahin monastery in Georgia, and translated into Russian by Prince Argutinsky in the *Sibirsky Vvestnik* for 1822, pp. 69, etc. This Russian version was again translated into French by Klaproth in the *Nouveau Journal asiatique* for 1833 (vol. xii., pp. 273, etc.). Another French translation was made direct from the Armenian by M. Brosset in the *Mémoires de l'Académie des Sciences de St. Pétersbourg* for 1870; a fresh Russian version of the original, by Prof. Patkanov, appeared in 1874. See also E. Bretschneider, *Medieval Researches from Eastern Asiatic Sources*, i. 164-172 (1888, "Trübner's Oriental" Series); C. R. Beazley, *Dawn of Modern Geography*, ii. 381-391 (1901).

(C. R. B.)

HAYWARD, ABRAHAM (1801-1884), translator of Goethe and author of *The Art of Dining*, was born at Wilton, near Salisbury. Educated at Blundell's school, Tiverton, he entered the Inner Temple in 1824, and was called to the bar in June 1832. Hayward edited the *Law Magazine* from 1829 to 1844, and became a conspicuous figure in London literary society. His translation of Goethe's *Faust* was privately printed in 1833, and a revised edition appeared in 1834. In Feb. 1835 he was elected to the Athenaeum club under Rule II., and he remained for nearly 50 years one of its most conspicuous and most influential members. He was also a subscriber to the Carlton, but ceased to frequent it when he became a Peelite. At the Temple, Hayward, whose reputation was rapidly growing as a connoisseur not only of a bill of fare (the famous *Art of Dining* appeared in 1852) but also (as Swift would have said) of a bill of company, gave famous dinners, at which ladies of fashion appreciated the wit of Sydney Smith and Theodore Hook, the dignity of Lockhart and Lyndhurst and the oratory of Macaulay. At the Athenaeum and in political society he to some extent succeeded to the position of Croker. His sharp pen made him many enemies. He disgusted the friends of Mill by the stories he raked up for an obituary notice of the great economist (*The Times*, May 10, 1873). He broke with Henry Reeve in 1874 by a venomous review of the *Greville Memoirs*, in which Reeve was compared to the beggarly Scot deputed to let off the blunderbuss which Bolingbroke (Greville) had charged. Samuel Warren attacked him (very unjustly, for Hayward was anything but a parasite) as Venom Tuft in *Ten Thousand a Year*; and Disraeli aimed at him partially in *Ste. Barbe* (in *Endymion*), though the satire here was directed primarily against Thackeray. After his break with Reeve, Hayward devoted himself more exclusively to the *Quarterly*. He died in London on Feb. 2, 1884.

Two volumes of Hayward's *Correspondence* (edited by H. E. Carlisle) were published in 1886. In *Vanity Fair* (Nov. 27, 1875) he may be seen as he appeared in later life.

HAYWARD, SIR JOHN (c. 1560-1627), English historian, was born at or near Felixstowe, Suffolk, where he was educated, and afterwards proceeded to Pembroke college, Cambridge. In 1599 he published *The First Part of the Life and Raigne of King Henrie IV.* dedicated to Robert Devereux, earl of Essex. This was reprinted in 1642. Queen Elizabeth and her advisers disliked the tone of the book and its dedication, and the queen ordered Francis Bacon to search it for "places in it that might be drawn within case of treason." Bacon reported "for treason surely I find none, but for felony very many," explaining that many of the sentences were stolen from Tacitus; but nevertheless Hayward was put in prison, where he remained until about 1601. On the accession of James I. in 1603 he courted the new king's favour by publishing two pamphlets, one of which, an argument in favour of the divine right of kings, was reprinted in 1683 as "The Right of Succession" by the friends of the duke of York during the struggle over the Exclusion Bill. He died in London on June 27, 1627. Hayward's other works are: *Lives of the Three Norman Kings of England* (1613), *The Life and Raigne of King Edward VI.* (posthumously printed, 1630, included in *Complete History of England*, anon., vol. ii. 1706) and *Certain Yeres of Queen Elizabeth's Raigne* (ed. John Bruce, Camden Society, 1840, with a life of the author).

HAYWOOD, ELIZA (1693?-1756), English writer, daughter of a London tradesman named Fowler, was born about 1693. She made an early and unhappy marriage, and her literary enemies circulated scandalous stories about her, possibly founded on her works rather than her real history. She appeared on the stage as early as 1715, and in 1721, after her elopement, she revised for Lincoln's Inn Fields *The Fair Captive*, by a Captain Hurst. Two other pieces followed, but she made her mark as a follower of Mrs. Manley in writing about 70 scandalous and voluminous novels. To *Memoirs of a certain Island adjacent to Utopia, written by a celebrated author of that country. Now translated into English* (1725), she appended a key in which the characters were explained by initials denoting living persons. The names are supplied to these initials in the copy in the British

Museum. *The Secret History of the Present Intrigues of the Court of Caramania* (1727) was explained in a similar manner. Pope attacked her in a coarse passage in *The Dunciad* (bk. ii. 11, 157 *et seq.*), which is aggravated by a note alluding to the "profligate licentiousness of those shameless scribblers (for the most part of that sex which ought least to be capable of such malice or impudence) who in libellous Memoirs and Novels reveal the faults or misfortunes of both sexes, to the ruin of public fame, or disturbance of private happiness." After some 16 years of practical silence, Mrs. Haywood achieved a certain success by her *Fortunate Foundlings* (1744); *Female Spectator* (1744-46), her ambitious character novel, *The History of Miss Betsy Thoughtless* (1751) and *The History of Jemmy and Jenny Jessamy* (1753). She died on Feb. 25, 1756.

A collected edition of her novels, plays and poems appeared in 1724, and her *Secret Histories, Novels and Poems* in 1725. See C. H. Whicher, *Life and romances of Mrs. Haywood* (1915) which contains a list of her writings and gives substantial extracts.

HAZĀRA, a district of British India, in the Peshawar division of the North-West Frontier Province (*q.v.*), with an area of 3,391 sq.m. It is bounded on the north by the Black mountain, the Swat country, Kohistan and Chilas; on the east by the native state of Kashmir; on the south by Rawalpindi district; and on the west by the river Indus. The district forms a wedge of territory extending far into the heart of the outer Himalayas, and consisting of a long narrow valley, shut in on both sides by lofty mountains, whose peaks rise to a height of 17,000 ft. above sea level. Towards the centre of the district the vale of Kagan is bounded by mountain chains, which sweep southward, and send off spurs on every side dividing the country into numerous minor dales. The district is well watered by the tributaries of the Indus, the Kunhar, which flows through the Kagan valley into the Jhelum, and many rivulets. To the north rise the distant peaks of the snow-clad ranges; midway, the central mountains stand clothed to their rounded summits with pines and other forest trees, while grass and brushwood spread a green cloak over the nearer hills, and cultivation covers every available slope. The chief frontier tribes on the border are the cis-Indus Swatis, Hasanzais, Akazais, Chagarzais, Pariari Syads, Madda Khels, Amazais and Umarzais. Within the district Pathans are not numerous. Pop. (1921), 622,349.

Hazāra is also the name of a race found in the Hazārājāt, the "thousands," or Hazāristān "Hazāraland," in Afghanistan, descended from military colonists settled by Jenghiz Khān in the highlands of the Upper Halmund and on the slopes of the Hindu Kūsh range north of Kabul. Probably of almost pure Mongolian origin, they now speak a Persian dialect. Strict Shi'as by sect they were only subjugated by the great Amir of Afghanistan, Abd-ur-Rahmān, in 1851, after a long resistance but were then enlisted in his engineer companies; and they are also recruited in pioneer regiments of the Indian Army. As Turks and Shi'as intermarriage with them is avoided by the Afghāns, and though they may have once taken Persian wives they have preserved the purity of the Mongolian type in a marked degree. In the western part of the Hazārājāt extending nearly to Herat and the Harūd valley the Hazāras include four tribes, Chahār Aimaq, which speak Turki and are Sunnis by sect.

See *The Encyclopaedia of Islam*, II., 1916, for full bibliographies.

HAZARD, a city of south-eastern Kentucky, U.S.A., on the Louisville and Nashville railroad; the county seat of Perry county, and a lumbering and coal-mining centre. The population was 4,348 in 1920, and was estimated locally at 10,000 in 1928. The city was founded in 1821 and incorporated in 1832.

HAZARD, a game of dice (called Craps in America), once very popular in England and played for large stakes at the famous rooms of Crockford (St. James's street, London) and Almack (Pall Mall, London). (Span. *azar*, unlucky throw at dice, misfortune, from Arab. *al*, and *zar*, dice.)

HAZARIBAGH, a town and district of British India, in the Chota Nagpur division of Behar and Orissa. The town is situated at an elevation of 2,000 feet. Pop. (1921), 17,060.

The DISTRICT comprises an area of 7,021 sq. miles. In 1921 the

population was 1,276,946. The physical formation of Hazaribagh exhibits three distinct features: (1) a high central plateau occupying the western section, the surface of which is undulating and cultivated; (2) a lower and more extensive plateau stretching along the north and eastern portions; to the north the land is well cultivated, while to the east the country is of a more varied character, the elevation is lower, and the character of a plateau is gradually lost; (3) the central valley of the Damodar river occupying the entire southern section. Although the salient characteristics of the district are rock, hill and wide-spreading jungle, fine stretches of cultivation are met with in all parts, and the scenery is generally pleasing and often striking. Rice and oil-seeds are the principal crops. The most important river is the Damodar, with its many tributaries, which drain an area of 2,480 sq. miles.

The district contains four important coalfields, the Giridih, Bokaro, Rangam and Karanpura coalfields. In the Giridih field, where the mines are owned and worked by the East Indian Railway company, the output in 1925 was over 750,000 tons. The Bokaro field produced 1½ million tons in the same year. The Karanpura field, which has suffered from lack of facilities for transport, is expected to develop with the extension of railways to the west and east. The district also contains a large part of a mica-producing belt, which extends into the districts of Gaya and Monghyr, and produces about half of the world's total output of mica. The production of shellac is another local industry of some importance. The sub-divisional town of Giridih, on which the export of coal has hitherto centred, has 18,874 inhabitants. Parasnath hill is annually visited by large numbers of Jain worshippers.

HAZEBROUCK, a town of northern France, in the department of Nord, on the canalized Bourre, 29 m. W.N.W. of Lille, on the Northern railway, between Lille and St. Omer. Pop. (1926) 11,640. It was a centre of movement for the Allies during the war of 1914-1918. Allenby occupied the town in Oct. 1914, and it remained in British hands throughout, being protected against the German advance by the forest of Nieppe. There is little of architectural interest in the town except the church of St. Eloi, a 16th century building with fine open work on the spire, and a 16th century convent, since converted into a hospital. Hazebrouck is the market for a fertile agricultural district, and has trade in live stock, grain and hops. Cloth weaving is the chief industry. Hazebrouck is an important railway junction.

HAZEL, botanically *Corylus*, a genus of shrubs or low trees of the family Betulaceae. The common Old World hazel, *Corylus avellana* (fig. 1), occurs throughout Europe, in North Africa and in central and Russian Asia, except the northernmost parts. It is commonly found in hedges and coppices, and as an undergrowth in woods, and reaches a height of some 12 ft.; occasionally it may attain to 30 ft. The bark of the older stems is of a bright brown, mottled with grey, that of the young twigs is ash-coloured, and glandular and hairy. The leaves are alternate, from 2 to 4 in. in length, downy below, roundish heart-shaped, pointed and shortly stalked. In the variety *C. purpurea*, the leaves, as also the pellicle of the kernel and the husk of the nut, are purple, and in *C. heterophylla* they are thickly clothed with hairs. The flowers are monoecious, and appear in Great Britain in Feb. and March, before the leaves. The cylindrical drooping yellow male catkins (fig. 1A) are 1 to 2½ in. long and occur 2 to 4 in a raceme; when in unusual numbers they may be terminal in position. The female flowers are small, sub-globose and sessile, resembling leaf-buds, and have protruding crimson stigmas; the minute inner bracts, by their enlargement, form the palmately lobed and cut involucre or husk of the nut. The ovary is not visible till nearly midsummer, and is not fully developed before autumn. The nuts have a length of from ½ to ¾ in., and grow in clusters. The wood of the hazel is whitish-red, close in texture and pliant, and has been used in cabinet-making, and for toys and turned articles. Curiously veined veneers are obtained from the roots; and the root-shoots are largely employed in the making of crates, coal-corves or baskets, hurdles and bands, whip-handles and other objects.

The filbert, among the numerous varieties of *Corylus avellana*,

is extensively cultivated, especially in Kent, for the sake of its nuts, which are readily distinguished from cob-nuts by their ample involucre and greater length. It may be propagated by suckers and layers, by grafting and by sowing.

In North America there are three native hazels, all with edible nuts somewhat smaller than those of the common hazel of Europe. The best known is the American hazel (*C. americana*), 3 ft. to 8

pumps, caskets and brushes. There is a large electric power plant. The assessed valuation of property in 1926 was \$26,531,768. Hazleton was founded in 1820; incorporated as a borough in 1856; and as a city in 1891. It has a commission form of government.

HAZLITT, WILLIAM (1778-1830), British literary critic and essayist, was born on April 10, 1778 at Maidstone, where his father, William Hazlitt, was minister of a Unitarian congregation. The father took the side of the Americans in their struggle with the mother-country, and during a residence at Bandon, Co. Cork, interested himself in the welfare of some American prisoners at Kinsale. In 1783 he migrated with his family to America, but in the winter of 1786-87 returned to England, and settled at Wem in Shropshire. His son William was sent in 1793 to the Hackney theological college. He returned, probably in 1794, to Wem, where he led a desultory life until 1802, and then decided to become a portrait painter. His elder brother John was already established as a miniature painter in London. In Jan. 1798 young Hazlitt heard S. T. Coleridge preach at Shrewsbury. Coleridge encouraged William Hazlitt's interest in metaphysics, and in the spring of the next year Hazlitt visited Coleridge at Nether Stowey and made the acquaintance of Wordsworth. On visits to his brother in London he began his long friendship with Charles Lamb, said to have been founded on a remark of Lamb's interpolated in a discussion between Coleridge, Godwin and Holcroft, "Give me man as he is *not* to be." In Oct. 1802 he went to Paris to copy portraits in the Louvre, and spent four happy months in Paris. He soon found he was not likely to excel as a portrait painter; his last portrait, one of Charles Lamb as a Venetian senator (now in the National Portrait Gallery), was executed in 1805. In that year he published his first book, *An Essay on the Principles of Human Action* . . . , which had occupied him at intervals for six or seven years. Other works followed.

In 1808 Hazlitt married Jane Stoddart. His domestic life was unhappy. His wife was an unromantic, business-like woman, while he himself was fitful and moody, and impatient of restraint. The dissolution of the ill-assorted union was nevertheless deferred for 14 years, during which much of Hazlitt's best literary work had been produced. Mrs. Hazlitt had inherited a small estate at Winterslow near Salisbury, and here the Hazlitts lived until 1812, when they removed to 19 York street, Westminster, a house that was once Milton's. Hazlitt was parliamentary reporter and subsequently dramatic critic for the *Morning Chronicle*; he also contributed to the *Champion* and *The Times*; but his closest connection was with the *Examiner*, owned by John and Leigh Hunt. In conjunction with Leigh Hunt he undertook the series of articles called *The Round Table*, a collection of essays on literature, men and manners which were originally contributed to the *Examiner*. To this time belong his *View of the English Stage* (1818), and *Lectures on the English Poets* (1818), on the *English Comic Writers* (1819), and on the *Dramatic Literature of the Age of Elizabeth* (1821). By these works, together with his *Characters of Shakespeare's Plays* (1817), and his *Table Talk; or Original Essays on Men and Manners* (1821-22), his reputation as a critic and essayist was established. Next to Coleridge, Hazlitt was perhaps the most powerful exponent of the dawning perception that Shakespeare's art was no less marvellous than his genius; and Hazlitt's criticism did not, like Coleridge's, remain in the condition of a series of brilliant but fitful glimpses of insight, but was elaborated with steady care. His lectures on the Elizabethan dramatists performed a similar service for the earlier, sweeter and simpler among them, such as Dekker, till then unduly eclipsed by later writers like Massinger.

As an essayist Hazlitt is equally great. He was intensely subjective, and the essence of his commentary, whatever the theme, is derived from himself. But Hazlitt's political sympathies and antipathies were vehement, and he had taken the unfashionable side. The *Quarterly Review* attacked him violently, stopped the sale of his writings for a time and blighted his credit with publishers. Hazlitt retaliated by his *Letter to William Gifford* (1819), accusing the editor of deliberate misrepresentation. In downright abuse and hard-hitting, Hazlitt proved himself more than a match even for Gifford. By the writers in *Blackwood's Magazine* Hazlitt

ft. high, with broadly oval pointed leaves, found in thickets from Maine to Ontario and Saskatchewan and southward to Florida and Kansas. The beaked hazel (*C. rostrata*), similar in size and aspect, but with the husk (involucre) enclosing the nut prolonged into a tubular beak, is found from Nova Scotia to British Columbia and southward to Georgia, Kansas and Oregon. The California hazel (*C. californica*), usually a shrub but sometimes a small tree 30 ft. high, occurs in forests from British Columbia to central California. (See FILBERT.)

HAZLETON, a city of Luzerne county, Pa., U.S.A., 30m. S. of Wilkes-Barre. It is on Federal highway 309, and is served by the Lehigh Valley, the Pennsylvania and the Wilkes-Barre and Hazleton (electric) railways. The population was 32,277 in 1920 (19% foreign-born white) and was estimated locally at over 39,000 in 1928. Hazleton is beautifully situated, on a broad tableland about 1,800ft. above sea-level on Nescopeck or Buck mountain, a spur of the Blue mountains. It is one of the important cities of the anthracite region, with large collieries surrounding it. The local coal industry dates from 1837. A hospital for the care of persons injured in the mines is maintained here by the State. The chief manufactures are silk, knit goods, shirts, iron, sheet steel,

was also scurrilously treated. He had become estranged from his early friends, the Lake poets, by what he uncharitably but not unnaturally regarded as their political apostasy. His inequalities of temper separated him for a time even from Leigh Hunt and Charles Lamb, and on the whole the period of his most brilliant literary success was that when he was most soured and broken. Domestic troubles supervened; he had gone to live in Southampton Buildings in Sept. 1819, and his marriage, long little more than nominal, was dissolved in consequence of the infatuated passion he had conceived for his landlord's daughter, Sarah Walker. His own record of the transaction, published by himself under the title of *Liber Amoris, or the New Pygmalion* (1823), is an unpleasant but remarkable psychological document. Later cured of his mistress, he married a widow, a Mrs. Bridgewater. They travelled on the Continent for a year and then parted finally. Hazlitt's study of the Italian masters during this tour, described in a series of letters contributed to the *Morning Chronicle*, had a deep effect upon him, and perhaps conduced to that intimacy with the cynical old painter Northcote which, shortly after his return, engendered a curious but eminently readable volume of *The Conversations of James Northcote, R.A.* (1830). The respective shares of author and artist are not always easy to determine. During the recent agitations of his life he had been writing essays, collected in 1826 under the title of *The Plain Speaker: opinions on Books, Men and Things* (1826). *The Spirit of the Age; or Contemporary Portraits* (1825), a series of criticisms on the leading intellectual characters of the day, is in point of style perhaps the most splendid and copious of his compositions. He now undertook a work which was to have crowned his literary reputation, but which can hardly be said to have even enhanced it—*The Life of Napoleon Buonaparte* (4 vols., 1828–30). Owing to the failure of his publishers Hazlitt received no recompense for this laborious work. He died on Sept. 18, 1830. Charles Lamb was with him to the last.

Hazlitt's grandson, WILLIAM CAREW HAZLITT, the bibliographer, was born on Aug. 22, 1834. He was educated at the Merchant Taylors' school and was called to the bar at the Inner Temple in 1861. Among his many publications may be noted his invaluable *Handbook to the Popular Poetical and Dramatic Literature of Great Britain, from the Invention of Printing to the Restoration* (1867), supplemented in 1876, 1882, 1887 and 1889, a *General Index* by J. G. Gray appearing in 1893. He published further contributions to the subject in *Bibliographical Collections and Notes on Early English Literature made during the years 1893–1903* (1903), and a *Manual for the Collector and Amateur of Old English Plays* . . . (1892). He was the chief editor of the useful 1871 edition of Warton's *History of English Poetry*, and compiled the *Catalogue of the Huth Library* (1880). He died in 1913.

The list of the first William Hazlitt's works also includes: *Political Essays, with Sketches of Public Characters* (1819); *Sketches of the Principal Picture Galleries in England* . . . (1824); *Characteristics; in the Manner of Rochefoucauld's Maxims* (1823); *Select Poets of Great Britain: to which are prefixed Critical Notices of each Author* (1825); *Notes of a Journey through France and Italy* . . . (1826); *The Life of Titian; with Anecdotes of the Distinguished Persons of his Time* (1830), nominally by James Northcote; an article on the "Fine Arts" contributed to the seventh edition of the *Encyclopædia Britannica*; and posthumous collections made by his son.

The Collected Works of William Hazlitt (12 vols., 1902–04), ed. A. R. Waller and A. Glover, with introd. by W. E. Henley, does not include the life of Napoleon. There are many modern reprints of isolated works. The most copious source of information respecting Hazlitt is the *Memoirs of William Hazlitt, with Portions of his Correspondence* (2 vols., 1867), by his grandson, W. C. Hazlitt, a medley rather than a memoir, yet full of interest. There is an excellent monograph on William Hazlitt (1902) by Augustine Birrell, in the "English Men of Letters" series, and one in French by J. Douady (1907), who also published a bibliography of his works. See also P. P. Howe, *Life of William Hazlitt* (1922). Valuable biographical particulars have been preserved in P. G. Patmore, *My Friends and Acquaintances* (1854); in Crabb Robinson's *Diary*; in Lamb's correspondence; and in W. C. Hazlitt, *Lamb and Hazlitt* (1900). A full bibliographical list of his writings, with a collection of the most remarkable critical judgments upon them from all quarters, was prepared by Alexander Ireland (1868). Further information on the Hazlitt family is to be found in W. C. Hazlitt, *Four Generations of a Literary Family* (2 vols., 1897).

HEAD, SIR EDMUND WALKER, 8TH BART. (1805–1868), English colonial governor and writer on art, born at Rayleigh, Essex, was educated at Winchester school and Oriel college, Oxford, and became fellow of Merton college. He had a distinguished career in the home and colonial service, and was governor-general of Canada from 1854 to 1861. He received many honours. Head died in London on Jan. 28, 1868. He edited F. T. Kugler's *Handbook of Painting of the German, Flemish, Dutch, Spanish and French Schools* (1854) and the *Essays on the Administrations of Great Britain* (1864), written by his lifelong friend, Sir George Cornwall Lewis. His translation from the Icelandic of *Viga Glum's Saga* appeared in 1866.

HEAD, the upper portion of the body in man, consisting of the skull with its integuments and contents, etc., connected with the trunk by the neck (see ANATOMY, SKULL, and BRAIN): also the anterior or fore part of other animals. The word is used in a large number of transferred and figurative senses.

HEAD-DRESS, a covering for the head, which may be considered as (1) protective, originating as a defence against climate and physical violence; (2) ceremonial, as a badge of rank and office. Frequently combining both functions, its history is bound up with the mask, the veil, the coiffure and the tonsure (*qq.v.*); its aesthetic development belongs to a later period.

The additions and changes made to the hair, the natural protection, whether defensive or ceremonial, appear first and chiefly among men. Women have worn their hair long, while men have cut their hair or shaved their heads. The practical band employed to confine the hair and keep it from the eyes, in wide-spread use among primitive and savage people, gave rise to a variety of head-dresses worn chiefly by women and surviving in historic civilization, while the comb and hair-pin, assuming ornamental forms, became essential elements in the woman's head-dress in many lands. Two pins, worn right and left, ornamented with artificial flowers and terminating in vestigial spoons are the usual hair ornaments among the women of eastern Asia.

Defensive and protective head-coverings fall into two general classes: (1) the hat and helmet type; (2) the cloth or garment tied around or worn over the head, such as the turban. The classic world of Greece and Rome, wearing a garment that when necessary was drawn over the head, eschewed other coverings. The hat or helmet arose as a hide or leather head-cover in the north and as a wood or basketry sun-shade in the tropics, metal being a later replacement. A round cap, made of cloth or felt, closely fitting the skull or terminating in a peak, and later truncate, appeared early in Western Asia. The turban was wound either directly around the head, or usually around such a cap. Its size, shape and colour varied in different countries and in accordance with the rank and occupation of the wearer, and to it, as well as to the felt cap an aigrette or jewel was sometimes added as a badge of regal and other rank.

Ceremonial head-dresses are varied and complex, and their beginnings may be traced to primitive conditions. Like the mask, they were assumed frequently to identify the wearer with a divinity or to perpetuate the tradition of a divine ancestor. Chinese imperial head-dresses bear the symbols of the sun and moon. The pointed crown may be regarded as a solar emblem. The custom of shaving the head was common at the initiation of a warrior or priest, but a head ornament or cap was commonly a badge of rank and its prerogatives jealously guarded. In China and Japan a straight, standing knot was left on the top of the head to which the imperial cap was attached by a transverse pin. The North American Indian warrior shaved his head, leaving a medial crest, or wore a similar crest made of the hair of the moose in which a tablet bearing the symbol of a bird was embedded. This object, tied to the so-called scalp lock, serves to explain the feathers fastened to his hair as well as his feather head-dresses. The peacock feather badge of the Chinese Manchu dynasty had a similar mechanism. The feathers of the Plains Indian war bonnets, assumed to symbolize exploits, may be regarded as a composite and cumulative expression of the bird on the tablet. The horns of these war bonnets are those of the buffalo. A miniature netted shield and two feathered darts, emblems of the Twin War

Gods, are of wide-spread recurrence in the head-dress of the Indian warrior. The aboriginal head-dresses of the Indian tribes of the North American continent may be regarded as emanations from ancient Mexico, where elaborate head-dresses of feathers were worn by the priests and warriors who personated the gods.

The military head-dress of historic Europe was in the main defensive, but the bear skin shako and lofty plumed hat of the 18th century were intended to increase the apparent height of the wearer and impress the enemy. Ecclesiastic head-dresses both East and West had secular origins.

The ceremonial crowns and head-dresses of women were borrowed and imitated from those of their consorts, whose rank they shared. The peasant wedding-crowns of central Europe are reminiscent. Flowers, natural and artificial, were their common and widely used hair ornaments, but the rule that women should not appear in church uncovered led to the universal use of the women's head-cloth or kerchief in Catholic Europe. The sun-bonnet is a combination of this cloth with a band, by which it was tied over the head.

The head-dress of fashion for both men and women reached its highest development in Europe in the 18th century. Its simplification due to the general adoption of short hair has resulted in the employment of the felt hat now generally worn by women in Europe and America. (See also DRESS; COSTUME DESIGN.)

HEAD-HUNTING. The practice of head-hunting, although due partly to the acquisitive instinct, arises from a belief in the existence of a more or less material soul matter on which all life depends. In the case of human beings this soul matter, often, apparently, in diminutive human form, is located particularly in the head. In abstracting a head the soul within is captured and thus added to the general stock of soul matter belonging to the community and so contributes to the fertility of the human population, the cattle and the crops; for the soul is conceived of, according to the Karens of Burma at any rate, as a sort of pupa, filled with a vaporose substance which bursts, when its contents spread over and fertilize the fields, passing again through the grain or herb eaten into the bodies of men or animals and so again into the seminal fluid enabling men and animals to propagate life. While precisely the same formula cannot be postulated of all head-hunters, head-hunting is generally based on a similar belief in a cycle of life dependent on the possession of soul (see METEMPSYCHOSIS).

Head-hunting is therefore associated (1) with ideas regarding the sanctity of the head as the seat of the soul, (2) with some forms of cannibalism where the body or part of the body is consumed in order to transfer to the eater the soul matter of the viand, (3) with phallic and often fertility cults intended to imbue the soil with productivity, and may thus develop into human sacrifice, a practice which has been generally associated with agriculture. Head-hunting, or at any rate some practice closely allied to it, is found sporadically all over the globe either actually existing or in some degenerate survival.

In Europe the actual survival of the practice is probably limited to the Balkan Peninsula, where the taking of the head affects the future life of the soul in some way that is no longer quite clear, but no doubt implied the transfer of the soul matter of the decapitated to the decapitator. Here the complete head was taken by Montenegrins at any rate as lately as 1912, the head being carried by the lock of hair worn apparently for that purpose. In the Balkan war of 1912-13, nose taking was substituted, and it was the practice to cut off the nose and upper lip with the moustache by which it was carried instead of the whole head, just as in Kafiristan and in Assam an ear is sometimes carried off instead of the whole head. In the British Isles the practice continued approximately to the end of the middle ages in Ireland and the Scottish marches, and, in the case of the Irish, Strabo accused them of honouring their dead relatives by eating their corpses, while a Martinmas pig is still killed that the fields may be sprinkled

with blood and so rendered fertile. In some parts of the Continent murderers have been known to eat part of their victims to secure themselves against ill-will on the part of the ghost. The underlying idea is, no doubt, that the consumption of the flesh leads to spiritual identity.

In Africa the principle involved has shown itself rather in the form of human sacrifice than of true head-hunting, Dahomey and

Ashanti being notorious examples; but even here the fact that the human sacrifices in Dahomey made the rain-magic more efficacious suggests the working of the same ideas, while we hear of a Matabele chief who anointed his body and fertilized his fields with human fat. So, too, the eating of an enemy's heart has been reported from Dahomey and Whydah, and the use of skulls as drinking cups from the Guinea coast. Bona fide head-hunting occurs in Nigeria, where a number of usages strongly suggest Indonesian culture. As in Indonesia, head-hunting among the Kagoro, and perhaps other tribes in Nigeria, is associated with the fertility of the crops and with marriage and with the service by the victim of the taker of his head in the next world.

In Asia Herodotus mentions head-hunters, and on a bas-relief from Nineveh in the British Museum is represented a battle in the 7th century B.C. between Assurbanipal and the king of Elam, in which the Assyrians are depicted as cutting and carrying off the heads of the slain. In Kafiristan on the north-west frontier of India head-hunting was practised until a recent date, wheat being showered by the women upon men returning with heads from a successful raid. In the north-east of India, Assam is famous for head-hunting. All the hill tribes living south of the Brahmaputra—Garos, Khasis, Nagas and Kukis—were head-hunters in the past, and many of the Naga tribes still practise the decaying cult.

Head-hunting in Assam is normally carried on by parties of raiders who depend on surprise tactics almost entirely. The heads, and sometimes also the hands and feet or even the whole limbs, are cut off and carried home to the village, where the head is usually placed on a stone or pile of stones kept for that purpose. The practice of cutting off the limbs has possibly a different origin, as there are tribes north of the Brahmaputra who do not take heads, but do cut off the feet and hands of slain enemies, presumably with a view to incapacitate the ghost. The skull is subsequently variously treated. After its virtue has passed into the stone on which it is laid it is either buried face downwards, as by the Angami tribe, hung up in trees, as by Semas and Lhotas, or suspended in the chief's house, or the bachelors' hall. In the latter case some tribes decorate it with a pair of buffalo horns, probably as a fertility symbol, and with long tassels of a broad-bladed grass which rustle pleasantly when the skull is swung by a dancer at a feast. In the case of several participants in a raid who are all in at the death, the head is often divided on a fixed

system, certain definite portions going to the first, second and third spears, etc. The insignia and, where tattooing is practised, the tattoo patterns worn by the successful warrior have specific reference to success in head-hunting. Thus the Angami warrior wears one hornbill feather for each success—"touching-meat" as it is called, while the Konyak warrior has his neck tattooed only if he has actually performed the act of decapitation in person, though he may tattoo his chest for "touching meat" and his face for the act of killing the enemy in person. With the Naga, the genuine head-hunter, a head must have cut its teeth to count, though a female head is at least as good as a male; but with the Kuki, whose cult is probably mixed and whose desire for heads is merely to supply a dead relative with servitors in another world, any head, even that of an embryo, is good. The Kagoro and Moroa tribes of West Africa, like the Kuki of Assam and the Kayans of Borneo, desire slaves in the next world rather than soul matter in this. The Naga never takes the head of a fellow-villager even though clan feuds within the village are very bitter and lead to much bloodshed, and even outside the village heads are not as a rule taken between men of the same or nearly related clans, a self-denying ordinance shared with the Kagoro. The younger women are everywhere great instigators of head-hunting, and refuse to marry men who have not "touched meat," probably with the idea that until they have taken life they are unlikely to beget offspring.

In Burma several tribes follow or have followed similar customs. The Wa tribe observe a definite head-hunting season when the fertilizing soul matter is required for the growing crop and all wayfarers move about at their peril. In Borneo, Indonesia generally, the Philippines, and Formosa, similar methods of head-hunting obtain, and the hill tribes of Malaya and Indo-China probably are or have been head-hunters at some period. The Ibans of Borneo are particularly enthusiastic in this respect. The practice was reported of the Philippines by Martin de Rada in 1577, and has barely disappeared among the Igorot and Tagalog of Luzon, while in Formosa it prevailed among the hill tribes. Elsewhere in Indonesia it extended through Ceram where the Alfurs were, or are, head-hunters, to New Guinea, where the Motu, like the Lhota Naga of Assam, wears a hornbill's head as the insignia of his achievement; here and there, as in the Battak country and in Timorlaut, it seems to be replaced by cannibalism.

In New Guinea the Tugeris use a bamboo knife for the act of decapitation, perhaps because iron would adversely affect the soul within. Throughout Oceania head-hunting prevailed till comparatively recently and possibly still occurs in the Solomon Islands. In the Solomon Islands the actual expedition to obtain a head formed the climax in a series of ceremonial acts extending over a number of years, and the suppression of head-hunting, on which depended an important part of the social life, has been a serious factor in the decay of society and the decrease of population which has followed under British administration. (See ANTHROPOLOGY.) Throughout Oceania head-hunting is closely associated with cannibalism and the latter institution has tended to obscure the former, but in many islands the importance attached to the head is unmistakable. In parts of Micronesia the head of the slain enemy was paraded about with dancing which served as an excuse for raising a fee for the chief to defray public expenditure, after which the head would be lent to another for the same purpose. In Melanesia the head is often mummified and preserved, and sometimes, as in New Britain, seems to be worn as a mask in order that the wearer may acquire the soul of the dead man. Even in Australia this underlying principle seems active as it is reported that the Australian believes that the spirit of a slain enemy enters the slayer. In New Zealand the heads of the foe were dried and preserved so that the tattoo marks and often the actual features were recognizable; this practice led to a development of head-hunting when tattooed heads became desirable curios and the demand of Europe for Maori trophies caused "pickled heads" to become a regular article of trade and export.

In North America the general practice was to take the scalp rather than the head, the idea probably being that the soul is located in the hair, an idea present in the Biblical story of Samson,

common in Malaya and Indonesia, where Nagas and Borneans use the hair of their dead enemies for ornaments, as did the North American Indians; in Oceania where the Marquesans use the hair of the victims of their cannibal rites for making arm rings and necklets of magic virtue; and frequent in South America, where the heads are often preserved, as by the Jibaros, by removing the skull and packing the skin with hot sand, thus shrinking it to the size of the head of a small monkey while preserving the features intact as a vivid portrait in caricature. Here, again, head-hunting is probably associated with cannibalism in a ceremonial form, and the heads of certain animals are also treated similarly (see LYCANTHROPY).

Head-hunting, therefore, is world-wide. It is associated with tribes still living in the stone ages, and may even go back to palaeolithic times; as in the Azilian deposits at Ofnet in Bavaria heads were found carefully decapitated and buried separately from the bodies, indicating beliefs in the special sanctity or importance of the head.

(J. H. H.)

HEALTH, a condition of physical soundness or well-being, in which an organism discharges its functions efficiently; also in a transferred sense a state of moral or intellectual well-being (see HYGIENE, THERAPEUTICS and PUBLIC HEALTH). "Health" represents the O.E. *hæleth*, the condition or state of being *hæl*, safe or sound.

Drinking of Healths.—The custom of drinking "health" to the living is probably derived from the ancient religious rite of drinking to the gods and the dead. The Greeks and Romans at meals poured out libations to their gods, and at ceremonial banquets drank to them and to the dead. The Norsemen drank the "minne" of Thor, Odin and Freya, and of their kings at their funeral feasts. With the advent of Christianity the pagan custom survived among the Scandinavian and Teutonic peoples. Such festal formulae as "God's minne!" "A bowl to God in Heaven!" occur. The Norse "minne" was at once love, memory and thought of the absent one. Associated with these customs must have been the drinking to the health of living men. The Greeks drank to one another and the Romans adopted the custom. The Goths pledged each other with the cry "Hails!" a greeting which had its counterpart in the Anglo-Saxon "wæs hæl" (see WASSAIL). The Roman gallants drank as many glasses to their mistresses as there were letters in each one's name. Thus Martial:

Six cups to Naevia's health go quickly round,
And be with seven the fair Justina's crown'd.

Toasts.—The English drinking phrase, a "toast," to "toast" anyone,—not older than the 17th century—had reference at first to this custom of drinking to the ladies. A toast was at first invariably a woman, and the origin of the phrase is curious. In Stuart days it was the custom to put a piece of toast in the wine-cup before drinking, from a notion that it gave the liquor a better flavour. In the *Tatler* No. 24, the connection between this sippet of toast and the fair one pledged is explained as follows: "It happened that on a publick day" (speaking of Bath in Charles II.'s reign) "a celebrated beauty of those times was in the cross bath, and one of the crowd of her admirers took a glass of the water in which the fair one stood, and drank her health to the company. There was in the place a gay fellow, half fuddled, who offered to jump in, and swore, though he liked not the liquor, he would have the toast. He was opposed in his resolu-

tion; yet this whim gave foundation to the present honour which is done to the lady we mention in our liquor, who has ever since been called a toast."

Health drinking had by the beginning of the 17th century become a very ceremonious business in England. Toasts were often drunk solemnly on bended knees; in 1668 at Sir George Carteret's at Cranbourne the health of the Duke of York was drunk by all in turn, each on his knees, the King, who was a guest, doing the like. A Scotch custom, still surviving, was to drink a toast with one foot on the table and one on the chair. Pepys, in his *Diary* for June 19, 1663, writes: "To the Rhenish wine house, where Mr. Moore showed us the French manner when a health is drunk, to bow to him that drunk to you, and then apply yourself to him, whose lady's health is drunk, and then to the person that you drink to, which I never knew before; but it seems it is now the fashion." At dinners to royalties, until the accession of Edward VII., finger-glasses were not placed on the table, because in early Georgian days those who were secretly Jacobites passed their wine-glasses over the finger-bowls before drinking the loyal toasts, in allusion to the royal exiles "over the water."

The Loving Cup.—The ceremony surrounding the loving cup to-day is reminiscent of the perils of those times when every man's hand was raised against his fellow. The "loving-cup" sometimes has a cover, and in this case each guest rises and bows to his immediate neighbour on the right, who, also rising, removes and holds the cover with his right hand while the other drinks; this is a survival of the days when he who drank was glad to have the assurance that the right or dagger hand of his neighbour was occupied in holding the lid of the chalice. When there is no cover it is a common custom for both the left- and the right-hand neighbour to rise while the loving cup is drunk, with the similar object of protecting the drinker from attack. The stirrup cup is probably the Roman *poculum boni genii*, the last glass drunk at the banquet to a general "good night."

HEALTH INSURANCE: see NATIONAL INSURANCE, *Health*.

HEALTH, MINISTRY OF: see GOVERNMENT DEPARTMENTS.

HEALTH VISITOR, a public or private official or other person whose duty it is to see that laws relating to public health and sanitation are obeyed.

The status of health visitors in Great Britain is now fully established by the Memorandum 101 MCW issued in Feb. 1925 by the Ministry of Health. Under that Memorandum, eight institutions were approved for the training of health visitors, five in London, one in Durham, one in Leeds and one in Bristol. After April 1, 1928, the appointment of women as whole time health visitors under a local authority is not approved unless they possess the new health visitor's certificate or the diploma given under the board of education. A health visitor's certificate can be obtained by a fully trained nurse who also holds the certificate of the central midwives board if she has taken a six months course in public health work followed by an examination. On the other hand if she is not a fully trained nurse, providing that she has had six months training in hospital and has undergone a recognized two years course of training at one of the institutions and has passed the necessary examination and holds the certificate of the central midwives board she is then entitled to take an appointment under a local authority. On March 31, 1927, there were 2,230 health visitors employed by local authorities in Great Britain and of these 936 were engaged wholly on maternity and child welfare work. The remaining 1,294 combined these duties with other public appointments such as those of school nurse or sanitary inspector. There were in addition 343 health visitors employed by voluntary agencies in connection with infant welfare centres and 1,390 district nurses employed by nursing associations were also utilized by county councils for health visiting in rural areas.

HEALY, TIMOTHY MICHAEL (1855—), was born at Bantry on May 17, 1855, the son of Maurice Healy, clerk of the Bantry Union. His mother was the daughter of a school-

master in this little west Cork town. Three of her brothers, A. M., T. D. and Donal Sullivan, became members of parliament, as did three of her sons, Thomas, Maurice and Timothy Healy. The eldest married his cousin, a daughter of T. D. Sullivan. This group of closely related politicians was the nucleus of the "Bantry Band" which included also W. M. Murphy, M.P., founder of *The Irish Independent*. In the succeeding generation, Kevin O'Higgins, Timothy Healy's nephew by marriage, became vice-president of the Irish Free State when his uncle was made its first governor-general.

Timothy began to earn his living at 13, and his early youth was spent as a shorthand clerk in a railway office at Newcastle-upon-Tyne. Here he became well known in Irish political and literary societies. In 1878 he moved to London and began in his spare time to contribute to the *New York Nation*. In 1879 Parnell on his first mission to America found that he needed a secretary and wired for Healy, who was already known to him. In 1880, after Parnell had been elected chairman of the Irish party, a parliamentary vacancy occurred in Wexford City, and Healy was elected.

From the first he slapped the House of Commons in the face, but he attended very closely to all its business. In 1881 Gladstone's Land bill began the revolution which gave the Catholic Irish ownership of the land instead of being mere cultivators under landlords. Gladstone said that, with the exception of three Irish law officers, only Healy understood it, and it is doubtful whether anybody but Healy understood the effect of the famous "Healy clause." Introduced as an amendment, this guaranteed that in future rent should not be chargeable on tenants' improvements. When the bill became an act, Healy, called to the bar in 1884, defended the tenants' interests in innumerable cases that arose in its application. In 1883 his audacious tongue secured him the distinction of being sent to gaol. Later in the year when a Liberal seat became vacant in County Monaghan he was selected to make the first Nationalist inroad on Ulster. He won. At the general election of 1885 with the extended franchise Monaghan became a safe seat. Healy attacked South Derry and won the constituency—by surprise tactics. In 1886, however, he was defeated, but was returned for North Lough.

His relations with Parnell now became less friendly, and he joined Biggar in opposing the candidature of Captain O'Shea for Galway City. The opposition was only overborne by Parnell's personal intervention. But in 1889, when the divorce petition against Parnell was undefended, Healy drafted the resolution carried by the party in favour of Parnell remaining at his post. "Parnell," he said, "is not a man, but an institution." Later, however, in face of Gladstone's declaration, he changed his mind, and from the time the "split" began, no speeches were so envenomed as Healy's. He was twice publicly beaten; but no form of menace had ever the least effect on him. In 1892 he became member for North Louth, and, as a member of the anti-Parnellite party to which the large majority of Irish Nationalists belonged, he was specially supported by the Catholic clergy. His rivals for leadership, William O'Brien and John Dillon, had more following among the laity, but Healy was always a priests' man. At this time he devoted less time to politics, for his practice at the bar was increasing, and in 1899 he became Q.C.

On the reunion of parties in 1900 he joined O'Brien in urging that Redmond, leader of the Parnellite minority, rather than John Dillon, leader of the anti-Parnellites, should be chosen as chairman of the united body. But a long indulgence in the savage spirit of faction which followed the Parnell "split" had rendered Healy difficult to work with, and in 1902, on the motion of O'Brien, he was expelled from the United Irish League, though he retained the support of the Catholic hierarchy and of Murphy's influential newspaper. In 1906 O'Brien, having split away from Redmond's main body with a few followers, made a working alliance with his former adversary and his brother Maurice, member for Cork City. In 1910, when Healy was beaten in North Louth, O'Brien provided him with a constituency in north-east Cork.

Healy joined the English bar in 1903 and took silk in 1910.

He was unceasingly employed on English cases, more especially of a political character, and defended many of the suffragettes. In parliament no speaker was more able to draw a crowded house, and his wit and eloquence were specially popular with the Tories, because he said more biting things of the Nationalist party than Englishmen could invent. With O'Brien he opposed the budget of 1909 which led to the clash with the House of Lords; and on the Home Rule measure of 1912, while giving it general support, he furiously opposed partition.

In 1914 he was a vigorous supporter of Britain in the World War, but the course of events from 1916 onwards, culminating in the introduction of conscription, drove him finally to side with Sinn Féin, and in 1918 he resigned his seat to allow an imprisoned Sinn Féiner to be returned. Little was publicly heard of him during the years of turmoil which followed until, at the close of 1922, the constitution of the Irish Free State having been made law by the Irish parliament, and subsequently by the British, the office of governor-general had to be filled. When Healy's name was first mentioned for the post there was general incredulity, but the appointment soon commended itself to Irishmen of all sections. The Free State Government, speaking through the mouth of Healy's nephew, Kevin O'Higgins, defended the choice of "an old man of the people," while others realized that Healy, though an extreme nationalist, had in many respects a most conservative mind. Those who feared the worst from a tongue and a temper which he had never before governed were surprised by the result; for during his continuance in office as the representative of King George Healy in no way added to the Government's difficulties, while he did more perhaps than any other person to cultivate the good will of the Protestant minority. He resigned office at the end of his three years' term, in Dec. 1927. In 1928 he published a volume of memoirs, *Letters and Leaders of My Day*. See Liam O'Flaherty, *Life of Tim Healy* (1927). (S. G.)

HEANOR, an urban district of Derbyshire, England, 10 m. N.W. of Nottingham by the L.N.E.R. Pop. (1921) 21,436. Hosiery works and collieries employ many of the inhabitants. The ruins of Codnor castle stand near some large ironworks.

HEARING. The air around us is constantly disturbed by vibrations, which travel through it in the form of waves (see SOUND). Similar wave movements are transmitted by water, and by most of the solid bodies by which we are surrounded. All animals higher in the scale of evolution than the amphibia, and many of those more primitive, have developed organs by which they are able to perceive these vibrations, and their relation to their environments is thereby greatly extended. The higher animals can signal to one another by means of the sounds which they themselves produce, and their hearing mechanism is able to interpret the purport of such signals. Articulate speech and music are the highest development of this system of sound signals, and their interpretation necessitates a refined power of analysing sounds by the organ of hearing, with which is associated a corresponding development of the mental faculties. The word **HEARING** is used to denote both the process by which vibrations of sounds act upon the sense organs, and the particular sensation aroused in consciousness by such stimulation.

Range of Hearing.—Only those vibrations which recur within certain limits of frequency give a sensation of sound. These limits vary in different individuals. From 20 vibrations to 20,000 per second may be taken as the average range. Many animals hear sounds of much higher pitch than man is able to. On the other hand, fishes and many marine animals appear to be sensitive to relatively slow vibrations, but not to those more rapid.

The ear consists of three parts named the *outer*, *middle* and *inner ear* respectively. The outer ear collects sound waves, the middle ear transmits them to the inner ear which analyses them and converts them into nerve impulses, as which they are conducted to the brain, where they are received and interpreted. A description of the EAR is given under that heading. This section deals with its working, and with the adaptation of the structure of its various parts to the performance of their several functions.

The External Ear.—This is divided into the *auricle*, or flap of the ear, and the *meatus*. The human auricle acts, to a certain

extent, as a collector of sound waves, but it is far inferior in this respect to the auricles of many animals, notably the horse and the ass. Sound waves are gathered up by the hollow recess, the *concha*, and projected forward on to the back of the *tragus*, by which they are directed into the skin-lined passage, the auditory meatus, which leads to the drum of the ear. The auricle loses some of its collecting power if the hollows of the *concha* and *tragus* are filled with wax. The form of the human auricle is adapted to collect sounds coming from the front. This is an advantage to man in communicating with his fellows, enabling him to concentrate both sight and hearing on the source of sound. Sounds are then conducted to both ears equally, and the one ear reinforces the other. When one ear is defective sounds are best heard by turning the better hearing ear to the source of sound. The advantage of correlating sight and hearing is then lost. Consequently, the deaf subject, when listening to conversation, places his open hand behind the auricle, and projects it forward, so as to increase its efficiency as a collector of sound coming from the front, whilst at the same time he is able to supplement his hearing by watching the motion of the lips of the speaker. The power of hearing sounds coming from one side is only slightly lessened when the auricle on that side has been lost as the result of injury. It would appear that the auricle, in spite of its beautiful modelling and delicate curves, is more ornamental than useful. Man possesses but little power of moving his ears, the muscles serving that function being rudimentary. Many animals can both rotate their ears, and expand them, thereby increasing their utility as sound collectors, and helping them to locate the direction of the sounds.

The length of the auditory meatus is a little over 1 inch. The passage is irregular in width and curvature. This minimises resonance effects, but does not entirely obviate them. The intrinsic tone of the meatus varies in different individuals according to its size and shape, but is usually within the limits c^4 to g^6 . Sounds of the same pitch are heard reinforced. Helmholtz attributed the peculiarly penetrating quality of the note of the cricket to its pitch falling within this range.

The Middle Ear or Tympanum.—Waves of sound in air are of great length in comparison with the dimensions of the ear itself. They range from $\frac{1}{4}$ in. to 55 ft. The function of the conducting mechanism of the middle ear is to convert the alternating compressions and rarefactions of the air in the meatus caused by sound waves into mechanical pushes and pulls of much smaller

FIG. 1.—DIAGRAM OF SECTION THROUGH MIDDLE AND THE INTERNAL EAR. The drum membrane picks up the sound waves from the air in the meatus, and transmits them through the chain of small bones to the cochlea, where they are analyzed and transformed into stimulations of the nerve of hearing.

range, but greatly increased force, on the footplate of the stapes, by which they are transmitted to the inner ear. The air waves in the meatus impinge on the *drum membrane*, which separates the outer from the middle ear. This is an extremely light and delicate structure. Its inertia is, consequently, very small, and it readily picks up the waves of sound without any perceptible lag, and its movements cease just as promptly when the sound ceases. Its vibrations are "dead beat." It is shaped in a subtle curve, slightly bulging in the lower half and indrawn in the upper half. Its centre, where it is attached to the tip of the malleus, is

retracted. Consequently, the fibres of which it is composed are not tense in any direction, and it has no inherent period of vibration to cause "distortion" of the sound waves. The movements of the drum membrane are communicated to a chain of small bones, the *auditory ossicles*. In birds and amphibia there is only one ossicle—the *columella*—a straight rod connecting the centre of the membrane to the oval window. In mammals the ossicles are three in number, the *malleus* or hammer, the *incus* or anvil, and the *stapes* or stirrup. The "handle" of the hammer is firmly incorporated with the upper half of the drum membrane. The anvil consists of a body having a slightly concave surface, and two processes, one long and one short. The surface in the body of the anvil is jointed on to the head of the hammer, so that the two together form a curved lever. The long process lies nearly parallel to the handle of the hammer, but is somewhat shorter. The short process of the anvil fits into a depression in the wall of the middle ear cavity above the level of the drum membrane. Both bones are suspended in position by fibrous bands strung across the cavity at this level, and these supports form the axis of the lever, round which it rotates. The long process is connected by a ball-and-socket joint to the head of the stirrup. The name of this ossicle exactly expresses its shape. The footplate of the stirrup fits into an oval opening in the wall of the inner ear, named the *oval window*, to the margins of which it is connected by a fibrous membrane, but not sufficiently firmly to prevent a certain freedom of movement. The axis of the stirrup lies approximately parallel to the plane of movement of the curved lever formed by the hammer and anvil. The ratio of length of the short arm of the lever (*i.e.*, the long process of the anvil) to the long arm (*i.e.*, the handle of the hammer) is as 2:3. The amplitude of movement communicated by the lever to the stirrup is therefore only $\frac{2}{3}$ that of the tip of the handle of the hammer, but the force is increased in the proportion of 3:2. The movements of the stirrup within the niche of the oval window are not those of a simple piston, but rather those of a trap door. Albert Gray has shown that the footplate moves as though pivoted on an axis transverse to its greatest length, at the junction of its posterior third and anterior two-thirds. Its maximum movement is, therefore, at its extreme anterior edge.

As the area of the drum membrane greatly exceeds that of the oval window, the pressure transmitted by the ossicles is concentrated. This fact, and the mechanical advantage at which the lever works, increases the force of the impulses transmitted from the drum membrane to the inner ear about ninety times.

The tension of the chain of ossicles is controlled by two small muscles, the *tensor tympani* which pulls the handle of the hammer inwards towards the inner ear, and the *stapedius* which pulls on one of the arms of the stirrup, so as to withdraw the footplate from the niche of the oval window. The two muscles thus antagonise one another, and their combined action is to keep all the bones pressed closely into contact and to prevent any play in the joints by which they are connected. It is probable that this tightening up of the ossicular lever is part of the act of attention which distinguishes listening from casual hearing. The joint between the hammer and the anvil which connects the two arms of the lever is shaped so that it transmits directly pushes from the hammer to the anvil, but allows a certain amount of sliding movement when the hammer is pulled outwards. The advantage of this mechanism is probably as providing a safeguard against injury to the delicate structures of the inner ear in case of sudden distension of the middle ear cavity with air under pressure as may occur, for instance, in violent blowing of the nose. This forces the membrane and the hammer outwards, and would cause a violent drag on the footplate of the stirrup tending to wrench it out of the oval window, were it not for the forward slip of the hammer on the anvil, which breaks the force of the pull.

The middle ear cavity is filled with air. It has a ventilating shaft, the *Eustachian tube*, which communicates with the pharynx. In most people this tube is closed during rest, but opens with every swallowing movement, so that the air is frequently renewed, and its pressure is kept in equilibrium with that of the outer air.

Unless this equilibrium is maintained the drum membrane is sucked inwards and rendered tense. This diminishes the acuteness of hearing, and causes a feeling of pressure in the ears. These symptoms are relieved by swallowing. This is a matter of common experience to aviators and miners when rapidly ascending to levels of lower, or descending to levels of higher atmospheric pressure. Partial or absolute blockage of the Eustachian tube is one of the commonest causes of deafness.

The Inner Ear or Labyrinth.—This consists of a complicated series of cavities and canals enclosed by hard bone, and filled with clear fluid. Within these are suspended a second series of sacs and tubes with extremely delicate membranous walls which are also filled with fluid, and are richly supplied with nerves. They contain the sense organs. There is no direct communication between the two concentric systems of cavities. It was formerly thought that the whole organ was concerned with hearing, but it is now generally recognized that only the anterior cavity, the *cochlea*, is sensitive to sound. The rest of the organ is concerned with the maintenance of equilibrium in the various postures assumed during rest and progression. (See EQUILIBRIUM.)

The form of the cochlea exactly resembles a small snail shell, from which it takes its name. It measures $\frac{1}{4}$ by $\frac{1}{2}$ in. It consists of a tube or tunnel coiled spirally two and a half turns, and is surrounded by dense bone. The total length of the tube is rather less than an inch and a half. It diminishes in diameter as the spiral is ascended, and is more closely coiled at its apex than at its base. A minute shelf of bone runs round the inner wall of the coiled tube, from the outer edge of which a fibrous membrane, the *basilar membrane*, stretches across to the outer wall, to which it is attached by the wedge shaped *spiral ligament*. The basilar membrane is built up of a large number (some 25,000) of fine transverse fibres, covered over on either side by layers of soft gelatinous cells. The sensitive elements of the cochlea are disposed along the upper surface of the membrane. The spiral lamina and basilar membrane thus divide the tube of the cochlea along its whole length into an upper and lower chamber, the partition being partly bony and partly membranous. A second partition, *Reissner's membrane*, runs obliquely from the spiral lamina to the outer wall of the cochlea, forming with the basilar membrane a triangular compartment within the upper chamber, to enclose the sense organ. The function of this membrane seems to be to separate the fluid surrounding the sense elements (*the endolymph*) from the surrounding fluid (*the perilymph*). The basilar membrane is not continued quite to the apex of the cochlea, there being a small gap beyond it, the *helicotrema*, by which the upper and lower chambers communicate. There are two openings in

FIG. 2.—DIAGRAM SHOWING DIRECTION OF DISPLACEMENT OF FLUID, INDICATED BY ARROWS, WITHIN THE COCHLEA, WITH EACH IMPULSE TRANSMITTED FROM THE STIRRUP BONE, (a) FOR HIGH PITCHED TONE, (b) FOR MEDIUM PITCHED TONE

the bony wall separating the middle and inner ear. One, the *oval window*, is filled by the foot plate of the stapes. It opens into the upper compartment. The other, the *round window*, communicates with the lower compartment, and is filled by a rather slack membrane. (Figs. 2 and 3.)

A simple diagram (fig. 2) will help to illustrate the mechanics of the inner ear. Suppose the cochlear tube to be rolled out straight, we have then a long tube, enclosed in rigid walls, divided horizontally by a yielding partition, the basilar membrane. At the near end we have the oval window opening into the upper

chamber, and the round window into the lower. At the far end is the helicotrema. Sound impulses transmitted from the drum membrane through the chain of ossicles to the stirrup tend to drive the foot plate inwards, and, consequently, to increase the pressure of the fluid within the cochlea. This causes the membrane of the round window to bulge outwards, as this is the only part of the enclosing walls which is not rigid. The consequent displacement of fluid must take place either through the helicotrema, or by bulging the basilar membrane downwards. It is only comparatively slow changes of pressure which cause to and fro movements at the helicotrema. Rapid alternations of pressure, such as those caused by sound waves, are transmitted through the cochlea across the basilar membrane, which is set in vibration. The movements of the basilar membrane stimulate the sensitive cells attached to its upper surface, by means of which a sense of hearing is aroused.

The Sensitive Mechanism.—The actual sense elements are certain elongated epithelial cells, each of which carries a row of fine hairs projecting from its free surface, called *hair cells*. In birds and amphibia the hair cells are simply packed in transverse rows on the basilar membrane. In mammals the cells are fewer in number, and are placed within the recesses of an elaborate supporting structure of *Corti's organ*, which lies on the inner half of the membrane. The framework of Corti's organ is composed of rather stiff fibres, which retain the delicate hair cells in position and protect them from pressure. This supporting framework also raises the free ends of the cells well above the surface of the basilar membrane, and increases their range of movement when the latter is vibrating. The sensory hairs project above the flat surface of Corti's organ into the substance of the *tectorial membrane*, which consists of a mass of soft jelly enmeshed in a fine network of fibres, and tethered to the outer end of the spiral lamina. Its purpose is to clog the movements of the hair processes, so that when Corti's organ is vibrating, the hairs are pulled first in one direction and then in another. Each hair cell has a nerve fibre attached to it. The hairs act like triggers. When pulled upon they release a discharge of energy from the hair cells, which travels as a nerve current through the auditory nerve to the hearing centre in the brain. According to Retzius there are about 20,000 auditory nerve-fibres connected with Corti's organ.

Analysis of Sound.—We not only hear sounds but we are able to interpret them. This implies that we distinguish the characteristic features of the different sounds which reach us. Sound waves differ in *intensity* and *pitch*. Intensity corresponds to the degree of condensation and rarefaction of the air in the successive phases of sound waves. Pitch signifies the number of waves arriving in a given time, or, what comes to the same thing, the duration of the individual waves. The greater the frequency the higher the pitch. Nearly all sounds we hear contain a mixture of pitches. In the case of *musical sounds* the form of the wave repeats itself regularly. In *noises* there is no such regularity. *Musical sounds* are either *simple tones*, which are made up of a succession of pendular vibrations all alike, or *compound tones*, composed of successive sets of waves of more or less irregular form, but each set repeating the form of the preceding set. According to Fourier's theorem any recurring wave form can be analysed in one way and in one way only, into a *fundamental* and *harmonics*. The fundamental is a simple tone having the same frequency as the recurring segment of the compound musical tone. The harmonics are all simple multiples of this number, i.e., 2, 3, 4, 5, etc., times as frequent. These *partial tones* contained in the compound tone can be picked up separately by resonators. The trained musical ear can also detect them.

Noises, in spite of the irregularity of their wave forms, have pitch, or ranges of pitch, but these pitches are not so easy to detect as is the case with musical sounds. They too may be regarded as being composed of a number of different pitches, but the components are usually very numerous, and are not distributed in a harmonic series. The constituent pitches can, however, be picked out by resonators.

It follows that the nerve impulses which are sent to the brain

from the cochlea must carry with them some criterion by which the *pitch* of the various constituents of the sounds may be recognised, and also the relative *intensity* of those constituents; and, further, if these two factors are determined, all sounds, musical or otherwise, can be distinguished. There is one other important characteristic of sound, and that is the rate at which the various alternations of pitch and intensity follow one another. In music

this rate is regular and is called *rhythm*. In noises it is irregular, but it is none the less an important factor in determining the character of the noise.

Pitch Perception: Historical.—The problem of how we recognise the pitch of sounds, and detect the simple pitches contained in a compound tone, has for long been a subject of controversy. It follows from what has been said in the last paragraph that if it could be shown that the ear contains a series of resonators, each tuned to vibrate to notes of one pitch, and extending over the whole of the audible scale, and that if each of these resonators were connected by a nerve fibre to the brain, the problem would

FIG. 3.—DIAGRAMMATIC SECTION ACROSS THE TUBE OF THE COCHLEA. When the basilar membrane is vibrating, its movements are communicated to Corti's organ, on the upper surface of which are sensitive hair cells that project into the jelly mass of the tectorial membrane. The pulling of these hairs gives rise to the sensation of sound.

be solved in a simple manner. This explanation seems to have occurred independently to a number of the earlier investigators of the ear, amongst whom may be mentioned Cotugno, le Cat, Johannes Müller, Sir Charles Bell and Thomas Young. It was Helmholtz, however, who gave a definite form to the *resonance theory*, which is usually associated with his name. He based his conception on a generalization:—"The analysis of compound into simple pendular vibrations is an astounding property of the ear. When we turn to external nature for an analogue of such an analysis of periodic motion into simple motion, we find none but the phenomena of sympathetic resonance." Thus Helmholtz approached the study of the internal ear with the hope of recognizing in it the confirmation of this pronouncement. The anatomical evidence he was able to bring forward was, however, slight and unconvincing, and the objections were formidable. Not the least of these was the minute size of the cochlea. The fibres of which the basilar membrane is composed do not exceed $\frac{1}{50}$ of an inch at their longest, and yet it was supposed that they could vibrate to tones nearly two octaves below the pianoforte scale. At first enthusiastically received, there was subsequently a reaction in scientific opinion, and the theory for a long time was discredited. A number of alternative theories were proposed, none of which seems to offer a full explanation of the facts of hearing, while some have since been shown to be untenable. The theory most in favour for a time was the "telephone theory" of Rinne and Voltolini, which sought to evade this difficulty by referring pitch analysis to the brain. It was supposed that the whole basilar membrane vibrated like a telephone disc, and transmitted to the auditory nerve impulses which followed exactly every variation of frequency and intensity of the sound waves. It is now known that the nerve fibres do not conduct currents like the electric flow in wires, and that separate impulses are not transmitted at a greater rate than about 1,000 a second, a frequency much below that (viz., about 25,000) of the highest audible tones. So the theory fails.

The Resonance Theory of Pitch Perception.—Helmholtz' theory is that different pitches of sound impress themselves on the basilar membrane at different levels, and that, if the sound contains several pitches, each pitch causes a movement at a different level, and consequently stimulates a different set of nerves. The mechanical principle on which this happens is resonance. (*See SOUND*.) If a note of simple pitch be sounded near a harp or open piano, the string tuned to the same note is set in vibration, whilst the other strings remain silent. If a compound tone, such as a

vowel, is sung to the piano, the particular strings tuned to the various pitches contained in the compound tone each pick up the particular tone to which they are in tune, and a sound is given out by the combined vibration of these strings which can be recognized as the particular vowel sung. Helmholtz compared the transverse fibres composing the basilar membrane to the strings of a piano, and he suggested that each fibre or small group of fibres, was tuned to vibrate to one particular pitch. This conception was supported by Hensen's observation that the length of the fibres increases as the basilar membrane ascends towards the apex of the cochlea. The pitch of a stretched string depends on its length, its tension, and its mass, according to the formula for

vibrating strings: $n = \frac{1}{l} \sqrt{\frac{t}{m}}$, when n = number of vibrations per

sec., l = length in centimetres, t = tension in dynes, and m = mass in grammes of 1 cm. length of the string. Short, light, tense strings give high pitched tones; long, relatively loose and heavy strings give low tones.

The Resonating Mechanism of the Cochlea.—If the fibres of the basilar membrane are tuned to respond to tones ranging over ten octaves, they should show a wide range of variation in the factors, *length*, *tension* and *mass*. If this variation were in length alone, the longest fibres would have to be 1,000 times longer than the shortest. If they differed in mass, or in tension alone, the corresponding variations would have to be as 1:1,000,000. Measurements show a difference of a little more than 1:3 in the length of the fibres. By itself this is only sufficient to account for a range of less than one and a half octaves. The evidence for variation in tension was supplied by Dr. A. A. Gray of Glasgow in 1900, in his observations on the spiral ligament. This structure attaches the basilar membrane to the outer wall of the cochlea. It is made up of fine fibres, radiating fanwise from the outer end of the basilar fibres. Its most striking feature is a gradual increase in bulk and density from the apical to the basal end of the cochlea. This seems to point clearly to a corresponding increase in tension on the fibres to which it is connected. The tension would be greatest on the shortest fibres and least on the longest fibres, as required by theory. With regard to differentiation by mass, we have to consider not merely the mass of the fibres themselves, but also the load they carry. The load is supplied by the fluid in which they are immersed. Supposing the fibres to be vibrating at any particular level of the cochlea, there must be a corresponding oscillation of the fluid intervening between the vibrating fibres and the round and oval windows (see fig. 2). The further the level of vibration is from the windows, the greater will be the mass of fluid moving. Consequently, the more distant the fibres, the more heavily are they loaded. Thus the variations in all the three factors, length, tension and mass, are in accordance with the supposition that the fibres are tuned to a progressive range of pitch. This cannot be taken as an absolute proof of the theory, but it adds substance and verisimilitude to what appears at first sight a rather fanciful conception. In particular, the recognition of the part played by the fluid load explains the difficulty arising from the minute scale of the resonators. The fibres, though short, are very heavily weighted. This lowers their pitch. A model devised by Wilkinson embodies the mechanical principles outlined in the preceding paragraph. It represents a basilar membrane and round and oval windows in their relative positions. It is filled with water. Tuning forks applied to the stirrup set the basilar membrane vibrating at levels varying with the pitch of the tuning forks employed. The model illustrated roughly the supposed resonating mechanism of the cochlea.

Physiological Evidence in Favour of the Resonance Theory.—Yoshi showed that long continued subjection of guinea pigs to tones of one pitch produced damage to the cochlea at levels varying with the pitch. High pitched tones damaged the basal coil whilst lower pitches affected levels nearer the apex. Ritchie Rodger and Putelli found that in boiler makers' deafness loss of hearing was principally for those tones to which they were constantly subjected whilst at work. Weinberg and Allen found that fatigue induced by tones of one pitch caused relative deafness

for that pitch, but not for other pitches. All these observations tend to show the existence of separate pitch receptors in the ear, and those of Yoshi afford evidence that these receptors form a graduated series at different levels of the cochlea. Though by no means universally accepted, the resonance theory is advancing in favour with physiologists, as it is recognised that it offers a reasonable explanation of the main facts of hearing.

One great difficulty with the resonance (or any other) theory of hearing is that it seems impossible that the localisation of the vibration in the basilar membrane can correspond in sharpness and definition with the sense of pitch aroused. Some vibrations of fibres on either side of the maximum point must take place. How then do we hear a sound of single pitch? At present this question cannot be answered. Further research on the subject of the integration of nerve impulses may throw light on it. A. A. Gray has indicated a similar paradox in the sense of touch. When a small area of the skin is pressed upon by a blunt point, we feel the pressure at its point of maximum incidence, not on the whole area. Similarly we refer pitch to the level of maximum vibration of the basilar membrane.

The only serious rival of the resonance theory is Ewald's. From observations made on a model designed to illustrate the movements of the basilar membrane, he concluded that sound impulses evoke a number of evenly spaced "stationary waves" in the membrane, and that the number of these waves is different for each pitch. The membrane he used was not differentiated as to length, tension or mass. Consequently his conclusions can only have weight if the evidence for such differentiation in the cochlea is rejected. The application of his conception to the facts of hearing is full of difficulties. The same may be said of the "travelling bulge" theories of Hurst, Meyer and Ter Kuile which at one time met with considerable favour.

Perception of Intensity of Sound.—Sounds must have a certain intensity before they can be heard, but the ear is wonderfully sensitive. Rayleigh computed that the minimal energy of sound capable of being perceived by the cochlea is much the same as that of light exciting the retina, and that "the ear is able to recognise the addition and subtraction of densities far less than those to be found in our highest vacua." The sensitivity is greatest for pitches ranging from 500 to 6,000 vibrations a second. This range comprises the higher partial tones of human speech on which the distinction between the various vowels and consonants depends.

Perception of intensity of sound accords with Weber's law, which states that in order to produce a perceptible increase in intensity of a sensation an equal fraction must be added to the previous intensity of the stimulus, whatever its value. This means that the ear detects much smaller differences in loudness in weak than in loud sounds.

The Nature of Nerve Impulses.—The nerve current by means of which messages are conveyed to and from the brain is not continuous, like an electric current flowing in a battery circuit, but is made up from a succession of separate impulses, all of the same strength. Adrian has recently shown that intensity of sensation is dependent on the rate at which these impulses follow one another. The rhythm of the impulses in the auditory nerve depends on intensity, not on pitch. This finally disposes of the "central analysis" of pitch theory. When the ear receives a number of sounds at the same time we distinguish not only their relative pitch, but their relative loudness. This fact seems to indicate that each constituent of the sound is separately impressed on the basilar membrane at its appropriate pitch level, and with its appropriate amplitude of vibration.

Location of Sound.—Our judgment of the direction from which sound is reaching us depends mainly on the relative intensity of the sound in the two ears, it being loudest in the ear turned to the source. Location can be assisted by turning the head in different directions. High pitched sounds of short wave length cast a shadow, but low pitched sounds of long wave length bend round the head, and are heard with indistinguishable intensity in the two ears. Consequently pure tones of low pitch are difficult to locate. In the case of compound tones, the character of the sound in the two ears is altered by the weakening of the higher pitched

partials on the side of the sound shadow, and this gives a criterion for judgment of direction. It even makes it possible for familiar sounds to be located by persons deaf in one ear.

Beats.—According to the principle of interference (*see* SOUND) when two notes nearly of the same pitch are sounded together they will alternately augment and diminish each other. This gives rise to "beats." The number of beats per second equals the difference in number of vibrations in the two tones. The beats are heard as rhythmic variations in intensity. When they follow one another rapidly they are accompanied by a disagreeable sensation of roughness, which is at a maximum when the beats are about 32 a second. Helmholtz ascribed this roughness to an overlapping of the area of the basilar membrane set in vibration by each tone separately. The pitch of the two tones is distinguished by the relative position of the maximum points of the disturbance. As these points at either end of the disturbed area are vibrating at different rates the intermediate portion of the membrane will be moving in an irregular "flickering" manner. It is this "flickering" that causes the unpleasant roughness. With greater differences of pitch the maximum points are further apart, and the overlapping is less, or entirely absent.

Combination Tones.—When two tones of different pitch are sounded together moderately loud, both are heard separately, and there may also be heard a deeper tone of a frequency equal to the difference between the frequencies of the other two; for example, two tuning forks of 800 d.v. and 1,024 d.v. respectively yield a *difference tone* of 224 d.v. There is also another combination tone, the *summational tone*, whose frequency is the sum of the two tones evoking it. It is much more difficult to hear, and to explain. The numerical relationship of the difference tone to the generating tones is the same as that of beats, and it is usually held that the beats generate this tone when they become sufficiently rapid. However, the roughness of beats and the difference tone can sometimes be heard together, which seems to indicate that they act in a different way on the cochlea. Much controversy has raged on the subject of beats and combination tones, and it is argued that if the ear works on the principle of resonance they ought not to be heard. This would be true if the conducting mechanism of the ear were entirely free from distortion, and if the cochlea were a perfect resonator. It is probable that the ear fulfils neither of these conditions.

Consonance and Dissonance.—Some combinations of tones blend together and appear smooth, others appear to be rough. The smooth or *consonance* intervals in music correspond to simple numerical relationships between the number of vibrations of their components. All the harmonic partials with frequencies 1:2 (octave), 1:3 (twelfth), 1:4 (double octave), and so on, are perfectly consonant. Then follow in order of lessening consonance the intervals 2:3 (fifth) and 3:4 (fourth); then with increasing dissonance 3:5 (major sixth), 4:5 (major third), 5:8 (minor sixth) and 5:6 (minor third). Helmholtz pointed out that the simpler the numerical relationship between two tones, the more evenly spaced on the scale, in relation to one another, are the two series of harmonic partials accompanying each fundamental tone. Assuming a similar distribution of the vibrating levels produced by each of these partial tones on the basilar membrane, there would be least overlapping of the areas occupied by the several tones when the frequencies of the two primaries had the simple relationship characterizing consonant intervals. Dissonance he attributed to roughness produced by overlapping of the vibrating areas of either the primary tones or their harmonics. This might account for the quality of dissonance, but is an insufficient explanation of consonance, which is more than a mere absence of dissonance. There is a unity, a sense of blending, in consonance which is not a purely negative feature. The octave interval is unique. There is a sense of identity in tones an octave apart. They are felt to be the end of one stage and the beginning of another. Modern music makes free use of dissonant intervals, but it is built up on a background or framework of simple tonal relationships. Whether this has developed out of the exigencies of tuning in stringed instruments, or is imposed by some inherent graduation of the scale of the basilar membrane

on the basis of harmonic intervals, is too speculative a subject to be discussed here.

The subject of hearing has always been regarded as one of the most difficult problems of physiology. The cochlea is a small and extremely delicate organ deeply buried within recesses of one of the hardest bones in the body. This greatly increases the difficulty of investigating its structure and function. Many of the problems connected with hearing are still obscure, and call for further research. (G. Wt.)

HEARING, SENSE OF. The power of hearing, that is to say of perceiving waves of sound which are propagated in the atmosphere, has as yet been found, apart from the four-legged vertebrates, only in certain insects. The sense of hearing in animals is used chiefly in the seeking out of the sexes by each other; it is, indeed, usually the male which produces the sounds, and by the strength of the notes attracts the female. This applies just as much to crickets and grasshoppers as to frogs and birds. In many mammals also, the voice and the sense of hearing are very clearly associated with mating: we have but to think of the belling of the stag.

When the sense of hearing serves other purposes also, such as the avoidance of enemies, or, among gregarious animals, mutual understanding, it is a derivative condition of late development, which is found only in the highest animals, the birds and mammals, perhaps in some reptiles also. The frog pays no heed to the noise made by an approaching man, it is only when it sees him that it takes to the water. Crickets and grasshoppers behave in a corresponding manner.

The structure of the auditory organs has certain features in common in all animals, therefore also in the insects which we are about to consider more closely. A tympanum is always present, that is a stretched membrane, which catches the waves of sound, and is thus made to vibrate. In the most simple form, the sensory cells which are affected by sound waves are attached directly to the tympanum (as in Lepidoptera, grasshoppers and cicadas).

Only in the green grasshoppers do we find the sensory cells separated from the tympanum, as they are in vertebrates. The transmission of sound, in these animals, takes place in the following manner. The tympanic membrane is set in vibration; these vibrations are communicated to the tracheal vesicles, which adjoin the inner side of the tympanic membrane, and it is these secondary vibrations which stimulate the sensory cells. The arrangement of the sensory cells is difficult to describe in detail, and is best shown by the accompanying figures. Usually, each sensory cell in the ear of an insect is like a stretched chord, and therefore is particularly sensitive to vibrations. In the green grasshoppers, the arrangement of the cells is similar to that of a pianoforte, they increase in size regularly from one end of the organ to the other. Apparently, the different-sized cells react to different sounds, but of this we do not know anything for certain.

It is remarkable that the auditory organs of insects are not situated in the head, as we are accustomed to find in vertebrates. In crickets and green grasshoppers they are situated on the front legs; in grasshoppers, cicadas and Lepidoptera on the body.

Exact experiments to prove the power of hearing in insects have been made principally by Regen, of Vienna, who used crickets. For this purpose, he made use chiefly of the well-known singing match of the male crickets, which we may so often hear in the meadows in summertime. The insects chirp alternately, and excite one another to rivalry. In 500 experiments with normal insects, this alternate chirping took place 349 times: in experiments with insects in which the auditory organs had been previously destroyed, the singing match was observed only 13 times out of 500. From this it follows, not only that the crickets are indeed able to hear, but also, that they do so with the aid of those organs, which, from their structure, we consider to be auditory organs.

Of even greater importance are the researches of this investigator on the attraction of the female by the chirping of the male. Regen was able to show that the female cricket makes straight for the cage which contains the chirping male, although he is hidden from her sight. If the auditory organs of the female are

removed, this reaction ceases immediately. It is of particular technical interest that the chirping of the male can be conveyed over the telephone in the same way as the human voice. It may then be observed that a female situated in a quite different place will spring towards the apparatus which reproduces the sounds, just as if the male were really there.

Of the other insects which possess the power of hearing only the nocturnal Lepidoptera (owlet-moths and Geometridae) have as yet been studied. These, however, show a quite different condition.

Lepidoptera are, with only very few exceptions, dumb. They thus form an exception to the rule according to which only those animals, in general, can hear which also produce sounds. They react apparently only to the sounds made by their chief enemies, bats. Eggers was indeed able to show that squeaking sounds will induce nocturnal Lepidoptera to take to flight. The insects will swerve when actually in flight as soon as they hear this noise, thus, undoubtedly, avoiding the enemy which produces it. Some species which feign death when danger threatens react also to squeaking sounds in this characteristic manner.

In addition to these examples, there are numerous observations which show that, sometimes, those insects also which have no definitely specialised auditory organs may react to sounds.

Swarms of gnats become restless at the whistle of an engine. Water-beetles hastily dive below the surface when a particular high note is sounded in the neighbourhood of their aquarium. In these cases, the sound waves apparently affect hairs of some kind or another which vibrate in harmony with a particular note. We can hardly say, in these instances, that the insects *hear*. Man also is able to perceive acoustic vibrations with the hand, as, for instance, if he touches a box upon which is placed a vibrating tuning-fork. In this instance, he perceives the vibrations by means of the sense of touch, and the previously mentioned reactions of insects must also be considered as of this nature.

THE STATIC SENSE

In the lower animals, we frequently find sense-organs which were formerly considered, from their anatomical structure, to be auditory organs. We now know that they have a very different function, namely, to react to the stimulus of gravity. The structure and function of such a statocyst can be described in a few words. It usually consists of a ball-shaped vesicle, in the interior of which are two substances of different weight, a liquid, and a so-called *otolith*, which is better termed a *statolith*.

The latter, because of its greater specific gravity, always occupies the deepest portion of the vesicle. Such an organ serves, above all, to maintain equilibrium in flying or swimming. All flying and swimming animals take up a definite normal position during motion. Usually, they keep the back upwards (fishes, birds, most crustaceans); a few crustaceans swim with the ventral surface upwards. When the animal is in the normal position, the statolith is always in contact with a definite point in the vesicle wall, which is called the "normal point." If, for any reason, the animal fails to maintain its balance, the statolith now touches a different point in the sensitive vesicle wall. The stimulated sensory cells send an impulse to the brain, and this brings about a regulatory movement of the legs, fins, or wings, which brings the animal again into the normal position. The creature is thus automatically kept in equilibrium by the statocyst. We find such organs of equilibration in the Decapod Crustacea, in cuttlefish, and in swimming gasteropods and bivalves. Organs corresponding exactly anatomically to these are found in gasteropods and bivalves generally, but, as yet, we know nothing for certain about their function. Lastly, all vertebrates, also, have typical organs of equilibration.

The most simple method of proving experimentally that, in such cases, we are dealing with organs of equilibration is to remove the statocysts. Delage was the first to do this. If both of the balancing organs of a free-swimming gasteropod (*Pterotrachea*), of a crustacean (*Palaemon*, *Mysis*), or of some kind of fish are destroyed, the animal shows itself to be completely disorientated. It revolves about its longitudinal axis in swimming,

turns somersaults, and so on. In some cases, certainly, we have also to take into consideration the eyes. Crustaceans which are strong swimmers orientate themselves by means of the eyes as well as by the statocysts. They place themselves so that the light falls on their backs. Since, in the water, the light always comes from above, the correct swimming position of the animal is ensured by this attitude.

For this reason, no alteration in behaviour is to be observed in such a crustacean, under normal conditions of light, if the statocysts only are removed. If, however, the animal is, at the same time, deprived of its sight, it becomes completely disorientated; if the light is caused to fall upon it from below, it swims upon its back instead of upon its ventral side.

In addition to this method of investigating experimentally by operation the function on the statocysts, there is a second which can be applied to Crustacea. At the time of moulting, when the crustacean casts the whole of the chitinous covering of its body, the inner surfaces of the statocysts and the statoliths are also shed. After the moult, the creature, using its pincers, places new statoliths, usually sand-grains, in its statocysts, which are open to the exterior. If the animal is not supplied with sand, but instead is given filings of iron or nickel, it will employ these as statoliths, and thus we get an animal with statoliths which are sensitive to magnetic influences (Kreidl). If, while the creature remains quiet on the ground, we now hold a strong electro-magnet over its back, the iron statoliths are attracted to the dorsal region. They are now in exactly the same position as they occupy when a normal animal falls on its back. Just as in such an animal, the reaction to the stimulation of the sensory hairs appears as a regulatory movement through an angle of 180° . The animal throws itself violently upon its back, the statoliths, attracted by the magnet, come into contact with the ventral surface of the statocysts, and remain in this position, which is the normal one when the creature is in its ordinary attitude.

If one statocyst is left in the animal to be studied, it shows characteristic differences according to the species to which it belongs. Some, such as the freshwater crayfish, or the free-swimming gasteropods, are already very disturbed by this operation; they revolve about their longitudinal axes in swimming, to the right or to the left, according as the left or the right organ is missing.

Other species, such as certain strong-swimming crustaceans (*Mysis*, *Palaemon*) show, on the contrary, no disturbance. We may say, therefore, that in these animals one statocyst alone is sufficient to maintain equilibrium, while, in the others, the co-operation of both organs is necessary for normal functioning. This condition has been more definitely analysed. We may imagine that the two statocysts always work the one against the other. When the animal is in the normal position, the two statocysts function with equal strength, but are opposed the one to the other. In functioning, therefore, the one compensates the other. If, however, the animal is in an oblique position, the lower functions more vigorously than the upper, and brings about a return to the normal position.

The fact that the scallop and its relations possess asymmetrical statocysts is of some theoretical interest. The left one works more strongly than the right. While a normal symmetrical animal, from being in an oblique position finds itself back in the normal one, in which the plane of symmetry is vertical, just the opposite happens in the case of these bivalves, which, strange to say, are able to swim. If they are placed in water so that their median plane is vertical, they turn in swimming back into an oblique position, which for them is the normal one.

The statocysts have a quite different structure in some animals, in jellyfish, among others. These creatures, which float about upon the open sea, bear, on the margin of the umbrella, eight peculiar sense organs, which usually take the form of club-shaped projections, weighted at one end with crystals (auditory concretions). According to the position which such a tentaculocyst occupies in space, there is a difference in the pressure and pull on the nervous tissue at its base, and, therefore, the effect upon the swimming muscles, which are in connection with the nervous system, also differs. For this reason, the jellyfish *Cotylorhiza*

shows, when swimming, as is usual, in a vertical position, an equal activity in all its swimming muscles, which are drawn up into a ring. If, however, the animal is placed on its side, the tentaculocysts below and above occupy quite different positions; in the lower there is a stronger movement than in the upper, and the creature rights itself again. In most of the other jellyfish matters are indeed somewhat different, and are not yet fully understood.

While in all the cases previously mentioned the statocysts bring about compensatory movements which bring the animal, if it loses its balance, back into the normal position, we know, on the other hand, of instances in which such compensation is completely lacking. The common crab, which, as a rule, does not swim, but creeps about upon the floor of the sea, shows a very peculiar connection between the statocysts and the stalked eyes.

If such an animal is moved about in the hand, it may be seen that the stalked eyes endeavour to hold their field of vision, and move so that they adjust the effect of the movements of the body upon the field of vision. For example, if the crab is turned about its transverse axis, so that the head is downwards, the stalked eyes are directed upwards; they are turned downwards if the head region is raised. The meaning of this phenomenon at once becomes clear if we consider the behaviour of human beings.

Man also is able to move his head about in space, at will; to raise it, lower it, move it backwards or forwards, and, in spite of all these movements, is able to keep his eyes fixed on a particular object.

In both cases, in mammals and in crustaceans, it can be proved that the movements of the muscles of the eyes are chiefly determined by the organs of equilibration. If the statocysts of a crustacean are removed, these movements of the stalked eyes are no longer to be observed. To each position of the body in space there corresponds a single position of the eyes in relation to the body with which it is very closely bound up. The tendency of the eyes is always to adjust their position so that it will correspond to the position of the body in space.

In many cases, the statocyst does not serve in any way as an organ of equilibration, but makes it possible for the animal to move vertically upwards or downwards (positive and negative geotaxis). This kind of movement is found chiefly in animals which live in sand or marine ooze. It can easily be understood that, for certain functions of life, these creatures must be able to reach the open water above them, for example, for the deposition of eggs; on the other hand, they must also be able to withdraw into the sheltering sand when danger threatens. If we consider a worm which bears in its head a pair of such statocysts, we shall see that, in order to make sure of reaching the depths, it has only to place itself so that the statoliths touch the foremost points of the statocysts. The common lug-worm of the European coasts (*Arenicola marina*) is such an animal, so also are certain Holothurians (*Synapta*), and, lastly, the mud-dwelling isopods of the genera *Anthura* and *Cyathura*. Negative geotaxis, which directs the animal vertically upwards, can best be observed in our terrestrial gasteropods. If a handful of such creatures is thrown into a vessel full of water, they all creep vertically upwards on the glass wall, and thus escape death by drowning. It is probable that this movement also is connected with the statocysts, but, at present, there is no proof of this.

It is of interest, that an array of cases is known to science in which an active maintenance of equilibrium, or a strong geotactic movement is indeed present, but in which statocysts are absent. The anatomy of the majority of animals is so well-known today that it is very unlikely that organs exist which have been overlooked. We are forced to the conclusion that other organs have an auxiliary function as statocysts. In most animals, the internal organs are suspended from the abdominal wall by a number of slings, just as in man. It has been proved in some cases that the internal organs take over, in a certain measure, the rôle of statocysts. In accordance with the position which the animal occupies in space, the direction of the pull upon the suspensory sheets varies. This enables the animal to perceive its position in space. The starfish affords a fine example of this. If it is placed upon its back, it turns over again. If the stomach is filled with

iron filings, the animal lying upon its back, and an electro-magnet is brought near the ventral surface, the animal does not turn over, since the suspensory organs are now subjected to the same pull as that which they sustain when the creature is in its normal position. Geotactic movements in the absence of statocysts occur very frequently. They may be observed in sea-anemones, starfish and many other animals. (W. v. BUD.)

HEARN, LAFCADIO (1850-1904), author of books about Japan, was born on June 27, 1850 in Leucadia (pronounced Lefcadia, whence his name, which was one adopted by himself), one of the Greek Ionian islands. He was the son of Surgeon-major Charles Hearn, of King's County, Ireland, who, during the English occupation of the Ionian islands, was station there, and who married a Greek wife. Artistic and rather bohemian tastes were in Lafcadio Hearn's blood. His father's brother Richard was at one time a well-known member of the Barbizon set of artists, though he made no mark as a painter through his lack of energy. Young Hearn had rather a casual education, but was for a time (1865) at Ushaw Roman Catholic college, Durham. The religious faith in which he was brought up was, however, soon lost; and at 19, being thrown on his own resources, he went to America and at first picked up a living in the lower grades of newspaper work. The details are obscure, but he continued to occupy himself with journalism and with out-of-the-way observation and reading, and meanwhile his erratic, romantic and rather morbid idiosyncrasies developed. He was for some time in New Orleans, writing for the *Times Democrat*, and was sent by that paper for two years as correspondent to the West Indies, where he gathered material for his *Two Years in the French West Indies* (1890). At last, in 1891, he went to Japan with a commission as a newspaper correspondent, which was quickly broken off. But here he found his true sphere.

The list of his books on Japanese subjects tells its own tale: *Glimpses of Unfamiliar Japan* (1894); *Out of the East* (1895); *Kokoro* (1896); *Gleanings in Buddha Fields* (1897); *Exotics and Retrospections* (1898); *In Ghostly Japan* (1899); *Shadowings* (1900); *A Japanese Miscellany* (1901); *Kotto* (1902); *Japanese Fairy Tales and Kwaidan* (1903), and (published just after his death) *Japan, an Attempt at Interpretation* (1904), a study full of knowledge and insight. He became a teacher of English at the University of Tokyo, and soon fell completely under the spell of Japanese ideas. He married a Japanese wife, became a naturalized Japanese under the name of Yakumo Koizumi, and adopted the Buddhist religion. For the last two years of his life (he died on Sept. 26, 1904) his health was failing, and he was deprived of his lectureship at the university. But he had gradually become known to the world at large by the originality, power and literary charm of his writings. Lafcadio Hearn's books were indeed unique for their day in the literature about Japan, in their combination of real knowledge with a literary art which is often exquisite.

See Elizabeth Bisland, *The Life and Letters of Lafcadio Hearn* (2 vols., 1906); G. M. Gould, *Concerning Lafcadio Hearn* (1908).

HEARNE, SAMUEL (1745-1792), English explorer, was born in London. In 1756 he entered the navy, and was some time with Lord Hood; at the end of the Seven Years' War (1763) he took service with the Hudson's Bay Company. In 1768 he examined portions of the Hudson Bay coasts with a view to improving the cod fishery, and in 1769-1772 he was employed in north-western discovery, searching especially for certain copper mines described by Indians. His first attempt (Nov. 1769) failed through the desertion of his Indians; his second (Feb. 1770) through the breaking of his quadrant; but in his third (Dec. 1770 to June 1772) he was successful, not only discovering the copper of the Coppermine river basin, but tracing this river to the Arctic Ocean. He reappeared at Fort Prince of Wales on June 30, 1772. Becoming governor of this fort in 1775, he was taken prisoner by the French under La Pérouse in 1782. He returned to England in 1787 and died there in 1792.

See his posthumous *Journey from Prince of Wales Fort in Hudson's Bay to the Northern Ocean* (London, 1795).

HEARNE, THOMAS (1678-1735), English antiquary, was born in July 1678 at Littlefield Green, White Waltham, Berk-

shire, son of the parish clerk. Educated at St. Edmund Hall, Oxford, he became in 1699 assistant keeper of the Bodleian Library, where he worked on the catalogue of books, and in 1712 he was appointed second keeper. As a nonjuror he refused to take the oaths of allegiance to King George I., and early in 1716 he was deprived of his librarianship. He continued to reside in Oxford, and occupied himself in editing the English chroniclers. He died on June 10, 1735.

Hearne's most important work was done as editor of many of the English chroniclers, and until the appearance of the "Rolls" series his editions were in many cases the only ones extant. Very carefully prepared, they are still of the greatest value to historical students. Perhaps the most important of a long list are Benedict of Peterborough's (*Benedictus Abbas*) *De vita et gesta Henrici II. et Ricardi I.* (1735); John of Fordun's *Scotichronicon* (1722); the monk of Evesham's *Historia vitae et regni Ricardi* (1729); Robert of Gloucester's *Chronicle* (1724); the *Vita et gesta Henrici V.*, wrongly attributed to Thomas Elmham (1727); Titus Livy's *Vita Henrici V.* (1716); Walter of Hemingburgh's *Chronicon* (1731); and William of Newburgh's *Historia rerum Anglicarum* (1719). He also edited John Leland's *Itinerary* (1710-12) and the same author's *Collectanea* (1715); W. Camden's *Annales rerum Anglicarum et Hibernicarum regnante Elizabetha* (1717); Sir John Spelman's *Life of Alfred* (1709); and W. Roper's *Life of Sir Thomas More* (1716). Among his other compilations may be mentioned: *Reliquiae Bodleianae* (1703).

Hearne left his mss. to William Bedford, who sold them to Dr. Richard Rawlinson, who in his turn bequeathed them to the Bodleian. Two volumes of extracts from his voluminous diary were published by Philip Bliss (Oxford, 1857), and afterwards an enlarged edition in three volumes appeared (1869). A large part of his diary entitled *Remarks and Collections, 1705-1714*, edited by C. E. Doble and D. W. Rannie, has been published by the Oxford Historical Society (1885-98). *Bibliotheca Hearniana*, excerpts from the catalogue of Hearne's library, has been edited by B. Botfield (1848).

See *Impartial Memorials of the Life and Writings of Thomas Hearne by several hands* (1736); and W. D. Macray, *Annals of the Bodleian Library* (1890). Hearne's autobiography is published in W. Huddesford's *Lives of Leland, Hearne and Wood* (1772). T. Ouvry's *Letters addressed to Thomas Hearne* has been privately printed (1874).

HEARSAY, a legal term signifying facts given in evidence derived from indirect information, the circumstances under which such evidence is admitted being subject to considerable limitations. See EVIDENCE.

HEARSE, a vehicle for the conveyance of a dead body at a funeral (Fr. *herse*, a harrow), usually a four-wheeled car, with a roofed and enclosed body, which contains the coffin. This is the only current use of the word. Its earlier form was "herse," and meant, as the French word did, a harrow (*q.v.*). It was then used of a portcullis, and thus becomes a heraldic term, the "herse" being frequently borne as a "charge," as in the arms of the City of Westminster. In funeral ceremonies a "herse" or "hearse" seems first to have been a harrow-shaped framework of wood, to hold lighted tapers and decorations placed on a coffin; this developed into a pagoda-shaped erection of woodwork or metal for the funerals of royal or other distinguished persons. This held banners, candles, armorial bearings and other heraldic devices. An elaborate "hearse" was designed by Inigo Jones for the funeral of James I. The "hearse" is also found as a permanent erection, of iron or other metal, over tombs. There is a brass "hearse" in the Beauchamp chapel at Warwick castle, and one over the tomb of Robert Marmion and his wife at Tanfield church near Ripon.

HEARST, WILLIAM RANDOLPH (1863-), American publisher, was born in San Francisco in April 1863, the son of George Hearst, a California pioneer who amassed a large fortune in ranch and mining lands, and who served as U.S. senator from 1886 to 1893. He entered Harvard in 1882 and remained two years. Becoming interested in journalism, he visited Boston newspaper offices, studied newspapers from all parts of the country, and paid special attention to the success of the New York *World* under Joseph Pulitzer. On his return to California he took first, partial and in 1887 complete control of the San Francisco *Examiner*, which the elder Hearst had bought for political objects. Within two years he made this journal pay, and with an efficient staff used it for many newspaper experiments.

Hearst invaded New York journalism in Sept. 1895 by buying the unsuccessful *Morning Journal*, which he made a one-cent

newspaper of highly popular type. To it he brought many able workers, including Julian Hawthorne, E. W. Townsend, Stephen Crane, Julian Ralph, and the cartoonist Homer Davenport, while he immediately raided the New York *World* for the best members of Pulitzer's Sunday staff, including R. F. Outcault, the inventor of the modern coloured comic pictures. By the use of numerous illustrations, coloured magazine sections and glaring headlines, by sensational articles on crime and pseudo-scientific topics, and by a jingo policy in foreign affairs, the *Journal* (an evening edition was started in 1896) was shortly given an unprecedented circulation. On the day after the election in 1896 it printed 1,506,000 copies of its several editions. Under Hearst's control the *Journal* attacked England in the Venezuela affairs, supported Bryan in 1896, demanded war with Spain in 1897-98, launched a series of attacks against municipal "franchise grabs" and supported Bryan again in 1900, bitterly assailing McKinley and Mark Hanna as tools of the trusts. An editorial statement in April 1901 that "if bad institutions and bad men can be got rid of only by killing, then the killing must be done," led Roosevelt in his first message after McKinley's assassination to denounce "exploiters of sensationalism" in words which he later (1906) declared he meant for Hearst.

The success of the *Journal* led Hearst to establish the Chicago *American* in 1900, the Chicago *Examiner* in 1902, and the Boston *American* in 1904. Other newspapers were purchased in 1912, and in 1917 he launched an energetic policy of expansion, so that by 1925 he owned 25 newspapers in 17 cities, including every section of the United States. After 1904, when he supported Parker, he paid decreasing attention to editorial leadership, declaring in 1924 that "newspapers do not form the opinion of the public, but if they are to be successful they must express the opinion of the public." But he supported Wilson in 1912 and 1916; he opposed American entrance into the World War; he waged unremitting warfare against the League of Nations, and demanded payment of the war debts in full. Late in 1916 the British and French governments denied Hearst the use of their mails and cables. But in 1927 he suddenly emerged as the champion of a bond of close friendship and practical co-operation among all English-speaking countries, and vigorously pushed the proposal. In the 1928 campaign he favoured the Republican national ticket. All his newspapers made use of common features and articles, all showed a modified sensationalism, and with wide variations in State politics, all expressed the same national views. Meanwhile, he embarked in other publishing enterprises. He purchased the *Cosmopolitan* monthly in 1905, the *World To-day* in 1911, and *Harper's Bazaar* and other magazines, including *Nash's Magazine* in England, at later dates. He published books, chiefly fiction, and later in his career produced motion pictures on a large scale.

Hearst's rôle in politics was ambitious but unsuccessful. While serving two inactive terms in the national House (1903-07), he ran in 1905 for mayor of New York on an anti-Tammany municipal ownership ticket, and came within 3,000 votes of winning; and the following year, as Democratic nominee for governor of New York he was defeated by Charles E. Hughes. A heavier defeat for mayor of New York followed in 1909, and though he was later frequently suggested for mayor or governor till his quarrel with Alfred E. Smith in 1924 destroyed his Democratic following, he was never again nominated. His importance has lain in the huge scale of his newspaper operations, and though he hardly ranks as a great innovator—his sensationalism imitated Pulitzer's, while E. W. Scripps preceded him in forming a newspaper chain—the Hearst methods have profoundly influenced American journalism.

See John K. Winkler, *W. R. Hearst, An American Phenomenon* (1928). (A. N.)

HEART, ANATOMY OF. The heart in man is a four-chambered muscular bag, which lies in the cavity of the thorax between the two lungs. It is surrounded by another bag, the pericardium, for protective and lubricating purposes (see COELOM AND SEROUS MEMBRANES). Externally the heart is somewhat conical, its base being directed upward, backward, and to the right, its apex downward, forward, and to the left. In transverse

section the cone is flattened, so that there is an anterior and a posterior surface and a superior and inferior border. The superior border runs obliquely downward and to the left, the inferior border is horizontal (see fig. 1). The divisions between the four chambers of the heart (namely, the two auricles and two ventricles) are indicated on the surface by grooves, and when these are followed it will be seen that the right auricle and ventricle

FIG. 1.—THE THORACIC VISCERA. IN THIS DIAGRAM THE LUNGS ARE TURNED TO THE SIDE, AND THE PERICARDIUM IS REMOVED TO DISPLAY THE HEART

lie on the front and right side, while the left auricle and ventricle are behind and on the left.

The *right auricle* is situated at the base of the heart, and its outline is seen on looking at the organ from in front. Into the posterior part of it open the two venae cavae (see fig. 2). In front and to the left of the superior vena cava is the right auricular appendage which overlaps the front of the root of the aorta, while running obliquely from the front of one vena cava to the other is a shallow groove, which indicates the original separation between the true auricle in front and the sinus venosus behind. When the auricle is opened by turning the front wall to the right as a flap the following structures are exposed:

1. A series of ridges on the anterior wall and in the appendage, running downward from the last and at right angles to it, like the teeth of a comb; these are known as *musculi pectinati*.
2. The orifices of the superior and inferior vena cava.
3. The remains of the *Eustachian valve* (see fig. 2), which in the foetus directs the blood from the inferior vena cava, through the *foramen ovale*, into the left auricle.
4. On the posterior or septal wall, between the two auricles, is an oval depression, called the *fossa ovalis* (see fig. 2), the remains of the original communication between the two auricles. In about a quarter of all normal hearts there is a small valvular communication between the two auricles in the left margin of this depression.
5. On the left side, opening into the right ventricle, is the *right auriculo-ventricular opening*.

The *right ventricle* is a triangular cavity (see fig. 2) the base of which is largely formed by the auriculo-ventricular orifice. To the left of this it is continued up into the root of the pulmonary artery. Its anterior wall forms part of the anterior surface of the heart, while its posterior wall is chiefly formed by the septum ventriculorum, between it and the left ventricle. In transverse section it is crescentic, since the septal wall bulges into its cavity. In its interior the following structures are seen:

1. The *tricuspid valve* (see fig. 2) which guards against reflux

of blood into the right auricle. This consists of a short cylindrical curtain of fibrous tissue, which projects into the ventricle from the margin of the auriculo-ventricular aperture, while from its free edge three triangular flaps hang down, the bases of which touch one another.

2. The *chordae tendineae* are fine fibrous cords, which fasten the cusps to the musculi papillares and ventricular wall, and prevent the valve being turned inside out when the ventricle contracts.

3. The *columnae carneae* are fleshy columns, and are of three kinds. The first are attached to the wall of the ventricle in their whole length and are merely sculptured in relief, as it were; the second are attached by both ends and are free in the middle; while the third are known as the *musculi papillares* and are attached by one end to the ventricular wall, the other end giving attachment to the chordae tendineae. These musculi papillares are grouped into three bundles (fig. 2).

4. The *pulmonary valve* (see fig. 2) at the opening of the pulmonary artery has three crescentic, pocket-like cusps, which, when the ventricle is filling, completely close the aperture, but during the contraction of the ventricle fit into three small niches known as the *sinuses of Valsalva*, and so are quite out of the way of the escaping blood. In the middle of the free margin of each is a small knob called the *corpus Arantii* (see fig. 2), and on each side of this a thin crescent-shaped flap, the *lunula* (see fig. 2), which is only made of two layers of endocardium, whereas in the rest of the cusp there is a fibrous backing between these two layers.

The *left auricle* is situated at the back of the base of the heart, behind and to the left of the right auricle. Behind it are the oesophagus and the thoracic aorta. Internally, it is much lighter in colour than the other cavities, owing to the greater thickness of its endocardium. There are no musculi pectinati except in the auricular appendage. The openings of the four pulmonary veins, usually, are placed two on each side of the posterior wall. On the septal wall is a small depression which corresponds to the anterior part of the fossa ovalis and often forms a valvular communication with the right auricle. The auriculo-ventricular orifice is large and oval, and is directed downward and to the left.

Lying in the left auriculo-ventricular furrow, is the coronary sinus, which receives most of the veins returning the blood from the heart substance; these are the right and left coronary veins at each extremity and the posterior and left cardiac veins from below.

The *left ventricle* is conical, the base being above, behind and to the right, while the apex corresponds to the apex of the heart

FIG. 2.—DIAGRAM SHOWING CAVITIES OF RIGHT SIDE OF THE HEART

and lies opposite the fifth intercostal space, $3\frac{1}{2}$ in. from the mid line. The following structures are seen inside it:—

1. The *mitral valve* guarding the auriculo-ventricular opening has the same arrangement as the tricuspid, already described, save that there are only two cusps, named marginal and aortic, the latter of which is the larger.
2. The *chordae tendineae* and *columnae carneae* resemble those of the right ventricle, though there are only two bundles of musculi papillares instead of three. These are very large.
3. The *aortic valve* has the same structure as the pulmonary, but the cusps are more massive. From the anterior and left

posterior sinuses of Valsalva the coronary arteries arise.

The walls of the left ventricle are three times as thick as those of the right, except at the apex, where they are thinner. The septum ventriculorum is concave towards the left ventricle, so that a transverse section of that cavity is nearly circular. The greater part of it has nearly the same thickness as the rest of the left ventricular wall and is muscular, but a small portion of the upper part is membranous and thin; it lies between the aortic and pulmonary orifices.

Structure of the Heart.—The arrangement of the muscular fibres of the heart is very complicated and only imperfectly known. For details one of the larger manuals, such as Cunningham's *Anatomy* (1922), or Gray's *Anatomy* (1926), should be consulted. The general scheme is that there are superficial fibres common to the two auricles and two ventricles and deeper fibres for each cavity. Passing from auricle to ventricle is a muscular bundle (best seen in the heart of young Ruminants) through which the wave of contraction passes from the auricles to the ventricles.

The *central fibrous body* is a triangular mass of fibro-cartilage, situated between the two auriculo-ventricular and the aortic orifices. The upper part of the septum ventriculorum blends with it. The endocardium is a delicate layer of endothelial cells backed by a very thin layer of fibro-elastic tissue; it is continuous with the endothelium of the great vessels and lines the whole of the cavities of the heart.

The heart is roughly as large as the closed fist and weighs from 8 to 120z.; it continues to increase in size up to about 50 years of age, but the increase is more marked in the male than in the female. Each ventricle holds about 4 f. oz. of blood, and each auricle rather less. The nerves of the heart are derived from the vagus, spinal accessory and sympathetic, through the superficial and deep cardiac plexuses.

EMBRYOLOGY.

In the article on the arteries (*q.v.*) the formation and coalescence of the two *primitive ventral aortae* to form the heart are noticed, so that we may here start with a straight median tube lying ventral to the pharynx and prolonged headwards into the ventral aortae and tailwards into the vitelline veins. This soon shows four dilations, which, from the tail towards the head end, are called the sinus venosus, the auricle, the ventricle and the truncus arteriosus. (This is often called *bulbus arteriosus*, but it will be seen that the term is used rather differently in comparative anatomy.) As the tubular heart grows more rapidly than the pericardium which contains it, it becomes bent into the form of an S laid on its side (S), the ventral convexity being

FIG. 3.—DIAGRAM OF THE FORMATION OF SOME OF THE SEPTA OF THE HEART, VIEWED FROM THE RIGHT SIDE

the ventricle and the dorsal the auricle. The passage from the auricle to the ventricle is known as the *auricular canal*, and in the dorsal and ventral parts of this appear two thickenings known as *endocardial cushions*, which approach one another and leave a transverse slit between them (see fig. 3). Eventually these two cushions fuse in the middle, obliterating the central part of the slit, while the lateral parts remain as the two auriculo-ventricular orifices; this fusion is known as the *septum intermedium*. From the bottom (ventral convexity) of the ventricle an antero-posterior median septum grows up, which is the *septum inferius* or *septum ventriculorum* (see fig. 3). Posteriorly (caudally) this septum fuses with the septum intermedium, but anteriorly it is free at the lower part of the truncus arteriosus. On referring to the development of the arteries (see ARTERIES) it will be seen that another septum starts between the last two pairs of aortic arches and grows tailwards until it reaches and joins with the septum inferius just mentioned. This septum aorticum (formed

by two ingrowths from the wall of the vessel which fuse later) becomes twisted in such a way that the right ventricle is continuous with the last pair of aortic arches (pulmonary artery), while the left ventricle communicates with the other arches (the permanent ventral aorta and its branches); it joins the septum ventriculorum in the upper part of the ventricular cavity and so forms the *pars membranacea septi* (fig. 3).

The fate of the sinus venosus and auricle must now be followed. Into the former, at first, only the two vitelline veins open, but later, as they develop, the *ducts of Cuvier* and the *umbilical veins* join in (see VEINS). As the ducts of Cuvier come from each side the sinus spreads out to meet them and becomes transversely elongated. The slight constriction, which at first is the only separation between the sinus and the auricle, becomes more marked, and later the opening is into the right part of the auricle. Later the right side of the sinus and the right part of the aperture enlarge until the back part of the right side of the auricle and the right part of the sinus venosus are thrown into one. The left part of the sinus venosus, which does not enlarge at the same rate as the right part, remains as the coronary sinus. It will now be seen why, in the adult heart, all the veins which open into the right auricle open into its posterior part. The permanent division between the two auricles occurs at a later date than that between the ventricles. It is formed by two partitions, the first of which, grows down from the auricular roof and ultimately reaches the endocardial cushions in the auricular canal. The other partition grows down on the right of the former and is never complete; it grows round and largely overlaps the foramen ovale and its edges form the annulus ovalis, so that, in the later months of foetal life, the foramen ovale is a valvular opening, the floor of which is formed by the first partition and the margins by the second. The closure of the foramen is brought about by adhesion of the two septa.

The pulmonary veins of the two sides at first join one another, dorsal to the left auricle, and open into that cavity by a single median trunk, but, as the auricle grows, this trunk and part of the right and left veins are absorbed into its cavity.

The mitral and tricuspid valves are formed by the shortening of the auricular canal which becomes telescoped into the ventricle, and the cusps are the remnants of this telescoping process.

The columnae carneae and chordae tendineae are the remains of a spongy network which originally filled the cavity of the primary ventricle.

The aortic and pulmonary valves are laid down in the ventral aorta, before it is divided into aorta and pulmonary artery, as four endocardial cushions; anterior, posterior, and two lateral. The septum aorticum cuts the latter two into two, so that each artery has the rudiments of three cusps.

Abnormalities of the heart are very numerous, and can usually be explained by a knowledge of its development. They may cause grave clinical symptoms. A clear and well illustrated review of the most important of them will be found in the chapter on congenital disease of the heart in *Clinical Applied Anatomy*, by C. R. Box and W. McAdam Eccles (1906).

BIBLIOGRAPHY.—For further details of the embryology of the heart see Oscar Hertwig's *Entwickelungslehre der Wirbeltiere* (1902); G. Born, "Entwicklung des Säugetierherzens," *Archiv f. mik. Anat.* Bd. 33 (1889); W. His, *Anatomie menschlicher Embryonen* (1881, 1885); Quain's *Anatomy*, vol. i. (1908); C. S. Minot, *Human Embryology* (1892); and A. Keith, *Human Embryology and Morphology* (1905).

COMPARATIVE ANATOMY

In the Acrania (*e.g.*, lancelet) there is no heart, though the vessels are specially contractile in the ventral part of the pharynx.

In the Cyclostomata (lamprey and hag), and Fishes, the heart has the arrangement which has been noticed in the human embryo. There is a smooth, thin-walled sinus venosus, a thin reticulate-walled auricle, produced laterally into two appendages, a thick-walled ventricle, and a *conus arteriosus* containing valves. In addition to these the beginning of the ventral aorta is often thickened and expanded to form a *bulbus arteriosus*, which is non-contractile, and, strictly speaking, should rather be described with the arteries than with the heart. Between the auricle and ventricle

is the auriculo-ventricular valve, which primarily consists of two cusps, comparable to the two endocardial cushions of the human embryo, though in some forms they may be subdivided. In the interior of the ventricle is a network of muscular trabeculae. The conus arteriosus in the Elasmobranchs (sharks and rays) and Ganoids (sturgeon) is large and provided with several rows of semilunar valves, but in the Cyclostomes (lamprey) and Teleosts (bony fishes) the conus is reduced and only the anterior (cephalic) row of valves retained. With the reduction of the conus the bulbus arteriosus is enlarged. So far the heart is a single tubular organ expanded into various cavities and having the characteristic *U*-shaped form seen in the human embryo; it contains only venous blood which is forced through the gills to be oxidized on its way to the tissues. In the Dipnoi (mud fish), in which rudimentary lungs, as well as gills, are developed, the auricle is divided into two, and the sinus venosus opens into the right auricle. The conus arteriosus too begins to be divided into two chambers, and in Protopterus this division is complete. This division of the heart is one instance in which the sequence of mammalian embryonic changes is not an epitome of evolutionary development—i.e., mammalian ontogeny does not repeat the processes of phylogeny, because in the human embryo the ventricular septum appears before the auricular.

In the Amphibia there are also two auricles and one ventricle, though in the Urodela (tailed amphibians) the auricular septum is often fenestrated. The sinus venosus is still a separate chamber, and the conus arteriosus, which may contain many or few valves, is usually divided into two by a spiral fold. Structurally the amphibian heart closely resembles the dipnoan, though the increased size of the left auricle is an advance. In the Anura (frogs and toads) the whole ventricle is filled with a spongy network which prevents the arterial and venous blood from the two auricles mixing to any great extent. (For the anatomy and physiology of the frog's heart, see *The Frog*, by Milnes Marshall.)

In the Reptiles the ventricular septum begins to appear; this in the lizards is quite incomplete, but in the crocodiles, which are usually regarded as the highest order of living reptiles, the partition has nearly reached the top of the ventricle, and the condition resembles that of the human embryo before the pars membranacea septi is formed. The conus arteriosus becomes included in the ventricular cavity, but the sinus venosus still remains distinct, and its opening into the right ventricle is guarded by two valves which closely resemble two venous valves in the auricle of the human embryo.

In the Birds the auricular and ventricular septa are complete; the right ventricle is thin-walled and crescentic in section, as in Man, and the muscoli papillares are developed. The left auriculo-ventricular valve has three membranous cusps with chordae tendineae attached to them, but the right auriculo-ventricular valve has a large fleshy cusp without chordae tendineae. The sinus venosus is largely included in the right auricle, but remains of the two venous valves are seen on each side of the orifice of the inferior vena cava.

In the Mammals the structure of the heart corresponds closely with the description of that of Man already given. In the Ornithorynchus, among the Monotremes, the right auriculo-ventricular valve has two fleshy and two membranous cusps, thus showing a resemblance to that of the bird. In the Echidna, the other member of the order, however, both auriculo-ventricular valves are membranous. In the Edentates the remains of the venous valves at the opening of the inferior vena cava are better marked than in other orders. In the Ungulates the moderator band in the right ventricle is especially well developed, and the central fibrous body at the base of the heart is often ossified, forming the os cordis so well known in the heart of the ox.

The position of the heart in the lower mammals is not so oblique as it is in Man.

BIBLIOGRAPHY.—For further details, see C. Rose, *Beitr. z. vergl. Anat. des Herzens der Wirbeltiere Morph. Jahrb.*, Bd. xvi. (1890); R. Wiedersheim, *Vergleichende Anatomie der Wirbeltiere* (Jena, 1902) (for literature).

HEART, COMPARATIVE PHYSIOLOGY OF. Mechanisms for the circulation of fluids through the body are found

in all except the simplest forms of animals, and such mechanisms appear to be a necessity for all animals which have specialised organs for respiration, digestion or excretion. Some of the chief functions of the circulation are as follows: (1) To carry oxygen from the organs of respiration to the rest of the body; (2) To carry food materials from the organs of digestion to the rest of the body; and (3) to remove from the tissues their waste products and to carry these to the organs of excretion. The transport of oxygen is the most urgent of these functions of the circulation because all animal tissues use oxygen continuously but are unable to store significant quantities. Hence the activity of all animal tissues is dependent on the circulation delivering to them a continuous supply of oxygen. The importance of the oxygen carrying function of the blood is indicated by the fact that the blood of nearly all animals contains some form of pigment that can combine with and transport to the tissues considerable quantities of oxygen. The haemoglobin of vertebrate blood is the best known of these pigments. The muscles that move the body use oxygen freely and the chief factor limiting continued muscular activity is the efficiency of the circulation; hence animals of an active habit of life require a much more efficient circulation than do animals which perform few movements. Animals do not develop complex mechanisms for which they have no need and hence the degree of development of the circulation varies to an extraordinary degree, because the complexity of circulatory apparatus needed depends on the mode of life of the animal and this often varies greatly in closely related animals. For example, of two Crustacea one may swim vigorously and the other may be sedentary, and in such a case the former will have a far better developed circulation than the latter. Generalisations concerning the circulation are therefore difficult, because in a single order of animals very wide variations in the development of circulatory mechanisms may exist. In this article examples will be chosen from those species which have a relatively well developed circulation, and the species with rudimentary or vestigial circulatory mechanisms will not be considered.

Tubular Hearts.—The common earth worm provides an excellent example of a primitive type of circulation. Down the back runs a tube filled with blood and down this tube from the tail to the head pass regular waves of contraction moving at a rate of about half an inch a second. These waves of contraction squeeze

the blood forward just as a thin rubber tube can be emptied by drawing a finger and thumb down it. Waves of contraction of this nature which pass along a structure are termed peristaltic waves. The blood is squeezed from the dorsal artery into arterioles, these connect with small veins and the veins empty into a ventral vein which returns the blood to the dorsal artery. Tubular hearts of this character may be regarded as the primitive type from which the more complex hearts have been developed. Hearts of this type are found in the worms and also in the ascidia. These last are a primitive group, which form a link between invertebrates and vertebrates. Moreover, the heart of the embryo vertebrate commences as a tubular structure.

FIG. 1.—HEART OF A CRAYFISH
The blood enters the heart through the ostia and is driven by the heart's contraction through the arteries

The Arthropod Heart.—The vast majority of living animals belong to the arthropod phylum which contains such classes as Crustacea, Arachnida and Insecta. This phylum may be divided into two great groups: firstly the Crustacea which breathe by gills, and secondly the spiders, scorpions and insects which are mostly land animals and which breathe partly or entirely by tracheae.

In the whole class of arthropods the circulatory apparatus has certain features in common. The heart is surrounded by a venous

sinus and the blood passes into the heart by means of holes or ostia provided with valves. When the heart contracts the contraction closes the ostia and drives the blood out through arteries. In most forms there is no proper system of capillaries and veins but the organs are surrounded by venous sinuses.

The gill breathing forms have fairly powerful hearts and fig. 1 shows the heart of the crayfish. The king-crab *Limulus* is noteworthy because it has a better developed circulatory system than any other arthropod. This form is a survival of a primitive type of arthropod and is intermediate between Crustacea and spiders. It possesses a closed circulatory system of arteries, capillaries and veins, and an exceptionally powerful heart. On the other hand, some of the smaller Crustacea have only very rudimentary circulatory mechanisms, without any true heart. The hearts of Crustacea are superior to those of other arthropods but are distinctly inferior to those of the mollusca; for example, it is fair to compare a crab and an octopus of similar size for both are cold-blooded, sea-living, gill-breathing animals of about equal activity, but the heart of the crab is a far simpler and weaker form of pump than is the heart of the octopus.

The tracheated arthropods include the spiders, scorpions and insects and all of these have extremely simple and inefficient hearts. The typical heart is a tubular structure running along the dorsum and is divided into segments by valves. Waves of contraction pass from behind forward driving the blood either forward or out through lateral arteries. The reason for the imperfect development of the heart in these forms is that they are not dependent on the circulation for their supply of oxygen, but breathe through minute branching tubes or tracheae which carry air from the surface of the body direct to the cells. This is a very efficient and economical respiratory mechanism for animals up to a certain size, as is indicated by the success of the class Insecta which contains more than half of the known species of animals, but in which the vast majority of species are less than one gram in weight.

Molluscan Hearts.—The molluscan circulation is arranged as follows: The blood returning from the body is collected in auricles and these contract and squeeze the blood into the ventricle which expels it into arteries. This arrangement forms a striking contrast to the arthropod heart in which the ventricle is suspended in a venous sinus. The contractile auricle ensures the proper filling of the ventricle, and represents an important advance in the efficiency of the heart as a pump. The vertebrate heart is of course constructed on the same principle.

In the highest molluscs, namely, the cephalopods (e.g., octopus) the circulatory mechanism is complex, for in addition to the chief heart accessory hearts are provided to pump the blood through the gills. This arrangement is shown in fig. 2. The difference between the efficiency of the arthropod and molluscan hearts is indicated by the fact that in the lobster, which is a particularly active crustacean, the arterial pressure is only 12cm. of water, whereas in the octopus the arterial pressure may rise as high as 115cm. of water.

The Development of the Vertebrate Heart.—A comparison of the circulation in the different classes of vertebrates reveals a series of arrangements of increasing complexity and efficiency. The vertebrates are descended from sea living forms and the hearts of the fishes may be compared as regards efficiency and complexity with the hearts of the higher molluscs. The change from water to land involved the substitution of lungs for gills, and this necessitated a considerable increase in circulatory efficiency. The heart of a frog, for example, is larger, more complex and much more efficient than the heart of a fish of the same size. The acquirement by vertebrates of the power to maintain a constant body temperature considerably above the temperature of their surroundings was a further change that involved even greater demands on the circulation, because the rate of oxygen consump-

tion is far higher in warm blooded than in cold blooded animals, and in fact the circulatory mechanisms of the birds and mammals are far more powerful and efficient than those of any invertebrates or cold blooded vertebrates.

Fish's Heart.—The heart of an elasmobranch such as the dog-fish is a good example of a primitive vertebrate heart. It consists of four divisions, the sinus venosus, the auricle, the ventricle and the bulbus arteriosus. Each of these chambers is divided by valves from its neighbours and the heart functions by a wave of contraction which passes down from the sinus to the bulbus arteriosus, and drives the blood before it from one chamber to another. This wave of contraction passes at a rate of about 4in. a second. When one chamber contracts, a certain interval is necessary to allow the blood to pass into and distend the next chamber and this time is provided by the wave of contraction being delayed for a fraction of a second between each of the chambers. The muscles forming all the chambers have the power to contract rhythmically without any stimulus being applied, but the natural rhythm of the sinus muscle is the highest and hence the sinus acts as a pacemaker to the rest of the heart. On the whole the hearts of the different classes of fishes do not differ in any important respect. The lampreys are the most primitive group of vertebrates and their hearts are slightly more

FIG. 3-A.—HEART OF A TADPOLE

primitive than the dog-fish heart, but the general arrangement and properties are the same. In the teleosts there is no true bulbus arteriosus, but otherwise there is no important difference from the elasmobranch heart. The dipnoi of lung fishes, however, show an important variation. This order is only represented by a few scattered species, but these show the first primitive attempt of a water-living vertebrate to acquire the power of air breathing. They possess lungs, and the veins from the lungs open into a portion of the auricle, which is separated from the rest by an incomplete septum. The oxygenated blood coming from the lungs is thus separated in the heart from the reduced blood that comes from the rest of the body.

FIG. 3-B.—HEART OF A TADPOLE SHORTLY BEFORE METAMORPHOSIS

The heart is developed by the differentiation of the simple tubular structure shown in fig. 3-A.

The heart is developed by the differentiation of the simple tubular structure shown in fig. 3-A.

Amphibian Heart.—The frog is a good example of this group and its heart shows special arrangements necessitated by air breathing. A special auricle has developed on the left and in this the aerated blood from the lungs is collected. The ventricle is not divided, but a complex system of valves in the bulbus arteriosus ensures that a large proportion of the aerated blood from the lungs shall pass to the head whilst a large proportion of the oxygen-poor venous blood from the rest of the body shall pass to the pulmonary arteries. Fig. 3-C shows the manner in which the frog's heart is developed by the convolution and differentiation of a simple tubular structure.

FIG. 3-C.—HEART OF ADULT FROG

The mechanism for the separation of exhausted and oxygenated blood is very imperfect in amphibia

The mechanism for the separation of exhausted and oxygenated blood is very imperfect in the case of the amphibian heart, and this may be one reason why the amphibia are a relatively unimportant group of animals.

Reptilian Hearts.—The process of division of the circulation into two distinct circuits is carried to completion in the reptiles.

In all reptiles there are two distinct auricles; in most genera the ventricle is only partly divided, but in the crocodiles the ventricle is divided into two separate chambers and thus the pulmonary or lung circulation is completely separated from the systemic or body circulation.

Birds and Mammals.—The hearts of the birds and mammals are more complex and far more powerful pumps than are those of the cold blooded vertebrates. The heart consists of four cham-

FIG. 4.—THE MAMMALIAN HEART, CONSISTING OF FOUR CHAMBERS. Venous blood passes into the right auricle through the vena cava, and is pumped by the right ventricle to the lungs, where it is oxygenated. It then returns to the left auricle by the pulmonary veins, and is pumped by the left ventricle to the systemic arteries.

bers, two auricles and two ventricles. The right auricle which receives the blood from the body represents the sinus venosus and the right portion of the auricle of the fish. The sinus venosus is reduced to a small but very important piece of tissue around the superior vena cava, an area known as the pace-maker of the heart (*cf.* fig. 4). The left auricle, which receives the blood from the lungs, represents the left half of the fish's auricle. The two ventricles have been derived by division of the single ventricle seen in the fish, whilst the bulbus arteriosus of the fish has disappeared. In this type of heart the venous blood returning from the body is collected in the right auricle and passes to the right ventricle which pumps it through the lungs. The lung veins return the blood to the left auricle and the left ventricle pumps the blood to the body tissues.

Conduction System.—The hearts of warm blooded animals have to work at a far greater pace than the hearts of cold blooded animals; *e.g.*, the frog's heart beats about 20 times a minute, whilst the mouse's heart beats from 500–1,000 times a minute. These high speeds obviously necessitate a very careful timing of the contractions of the different portions of the heart. This is achieved by the specialisation of certain tissues which conduct the impulses from chamber to chamber. These are shown in fig. 4. The remnant of the sinus venosus situated in the right auricle around the great veins is the pace-maker of the mammalian heart, and from here the impulse spreads all over the two auricles at a rate of about 40 in. a second, which is 10 times the rate of the conduction in the frog's heart. The auricles are of course firmly attached to the ventricles, but there is only one small bridge of tissue that is capable of carrying the wave of excitation from the auricles to the ventricle. This bridge is called the Bundle of His and consists of specialised muscle fibres called Purkinje fibres. The exact arrangement of the Bundle of His in birds is not well known, but in mammals it is a well defined bundle that first splits into two divisions which pass to the two ventricles and then branches out into a network of fibres covering the interior of the ventricles. At the commencement of the Purkinje system is a mass of small muscle cells called the auriculo-ventricular node and here the wave of excitation is checked for a fraction of a second (in man for about one-twentieth of a second), and then the contraction wave is carried rapidly down the Purkinje system so that it reaches all portions of the ventricle at almost the same instant.

This is an arrangement which allows sufficient time for the blood to move from auricle to ventricle when the auricle contracts and at the same time ensures that the whole ventricle shall contract

simultaneously. The high efficiency of the mammalian heart probably depends very largely on this peculiar timing mechanism. The remarkable adaptability of the heart as a pump is illustrated by the fact that all mammalian hearts are built on the same type, but the heart of a small mouse weighs about 0.15 grams whereas the hearts of the largest whales weigh about 200 kilos. Moreover there are huge variations in speed for the heart of the mouse can beat 1,000 times a minute whilst the heart of the horse beats only 30 times a minute. These examples show over what an extraordinary range of size and speed the mammalian heart is capable of functioning efficiently.

The Capacity of the Vertebrate Heart for Work.—An outstanding feature of the heart as a machine is its capacity to perform continuous work, for it beats continuously during the life of the body. In the case of the human heart, this contracts 100,000 times a day and the left ventricle daily expels some 10,000 litres of blood working against a resistance of 120 mm. of mercury. Another remarkable feature is the reserve power of the heart. The work that the heart does during bodily rest is only a fraction of the work it can do. The power of the body to perform long continued muscular exercise is limited by the amount of oxygen per minute that can be supplied to the muscles, and this again depends on the quantity of blood that the heart can expel per minute. The heart of a human athlete during violent exercise can expel three times as much blood per minute as it expels during bodily rest, but to perform this work the heart itself requires about one quarter of the blood it expels, for the heart's oxygen consumption during such violent exercise is nearly equal to the oxygen usage of the whole body when at rest. Athletic animals capable of feats of endurance such as the dog, the horse, the hare or man are characterized by having large hearts with great reserve powers. On the other hand animals which never need to perform continuous exertion have relatively small hearts with low reserve powers. The rabbit and hare form a striking contrast. The rabbit's heart weighs 2.7 parts per 1,000 parts of body weight, whilst the hare's heart weighs 7.5 parts per 1,000. Corresponding to this difference in weight the rabbit's pulse rate at rest is 205 which is about two-thirds of the maximum rate at which it can work, whereas the hare's pulse rate at rest is only 64 which is less than one quarter of its maximum rate.

Since the maximum output of the heart is greatly in excess of its normal output, it obviously requires some controlling mechanism to adjust its work to the bodily needs. This adjustment is partly effected by variations in the venous filling of the heart, for the heart muscle is so adjusted that the more complete the filling the more powerful the contraction. In addition the heart is controlled by two nerves, the vagus nerve which reduces the heart's frequency, and the sympathetic nerve which augments the frequency and the force of the beat. Augmentor and depressor nerves of this type are present in most invertebrate hearts and in all vertebrate hearts, but their activity is most marked in the case of athletic animals. For example cutting the vagus nerves increases the frequency of the hare's heart from 64 to 264 beats per minute, whereas cutting the vagus nerves in the rabbit only increases the frequency from 205 to 321 beats per minute.

Although the mammalian heart is a very efficient pump, yet there is a limit to the amount of work that can be done per minute by a given weight of muscle. The actual limiting fact is probably the maximum amount of blood, and consequently the maximum amount of oxygen, that can be supplied to the heart muscle per minute by the arteries of the heart (the coronary arteries). The oxygen required per unit weight by warm blooded animals varies inversely as the cube root of their body weight, and hence small animals require much more oxygen per unit weight than do large animals. For example the ox needs about 3.5 cc. of oxygen per minute per kilo. of body weight, whilst the mouse needs 17 times this quantity.

It is a striking fact that a very large number of species of birds and mammals weigh between 10 and 30 grams but very few weigh less than 10 grams. A probable reason for this fact is that the oxygen requirements per unit weight in the case of animals of 10 grams is so great that the heart has to do work at a rate

that approaches the maximum possible capacity of heart muscle.

See A. J. Clark, *Comparative Physiology of the Heart* (1927), also VASCULAR SYSTEM. (A. J. C.)

HEART, DISEASES OF THE. Diseases of the heart may be classified in two main groups: (1) Disease of the valves; and (2) Disease of the walls of the heart.

(1.) **Valvular Disease.**—Inflammation of the valves of the heart, or *endocarditis*, is the most common complication of rheumatism in children and young adults. More severe types, which are apt to prove fatal from a form of blood poisoning, may result when the valves are attacked by pneumococci, pyogenic streptococci and staphylococci, gonococci, or influenza bacilli. As a result of endocarditis, one or more of the valves may be damaged, so that it leaks, the aortic and mitral valves being affected far more commonly than those of the right side. In the process of healing, scar tissue is formed which has a tendency to contract, so that in some cases the orifice of the valve becomes narrowed. We may thus have incompetence or stenosis of a valve or both combined.

Valvular lesions are detected on auscultation by the blowing sounds or murmurs to which they give rise. Thus, lesions of the mitral valve give rise to murmurs heard at the apex beat, and lesions of the aortic valves to murmurs heard in the second right inter-costal space. Accurate timing of the murmurs in relation to the heart sounds indicates whether the murmur is due to stenosis or incompetence. If the valvular lesion is severe, changes must take place in the heart cavities and muscle to compensate for the effects of the regurgitation or obstruction, as the case may be, or the circulation would fail. In affections of the aortic valve, the extra work falls on the left ventricle, which dilates and hypertrophies. In affections of the mitral valve the effect is felt primarily by the left auricle, a thin walled structure incapable of undergoing the requisite increase in power to resist the backward flow through the mitral orifice in case of leakage, or to overcome the effects of obstruction in case of stenosis. The back pressure is therefore transmitted to the pulmonary circulation, and as the right ventricle is responsible for maintaining the flow of blood through the lungs, the strain and extra work fall on the right ventricle, which in turn dilates and hypertrophies. The degree of hypertrophy of the left or right ventricle is thus, up to a point, a measure of the extent of the lesion of the aortic or mitral valve respectively. When the effects of the valvular lesion are so neutralized by these structural changes in the heart that the circulation is equally maintained, "compensation" is said to be efficient.

When the heart gives way under the strain, compensation is said to break down, and dropsy, shortness of breath, cough and cyanosis are among the distressing symptoms which may set in. The mere existence of a valvular lesion is unimportant if compensation is efficient, and many persons with slight valvular lesions are living lives indistinguishable from those of their neighbours. But with more serious lesions certain precautions should be observed in regard to over-exertion, excitement, over-indulgence in tobacco or alcohol, etc., as additional strain on the heart may cause a breakdown of compensation. When this occurs treatment is required. Rest in bed may be sufficient or may need to be supplemented by drugs such as digitalis, convallaria or strychnine.

(2.) **Affections of the Muscular Wall of the Heart.**—Dilatation of the heart is an incident in the earlier stages of valvular disease antecedent to hypertrophy. Temporary dilatation of the heart occurs in violent exertion, but rapidly subsides and is not harmful to the sound and vigorous heart of the young. But if the heart muscle is weak and flabby from a too sedentary life or from degenerative changes, or during convalescence from a severe illness, circumstances which will not injure a healthy heart, may give rise to serious dilatation from which recovery may be protracted. Influenza is a common cause of cardiac dilatation after the acute illness has subsided, if the patient resumes his ordinary life too soon. Fatty or fibroid degeneration of the heart wall may occur in later life if the nutrient blood-vessels are the seat of arterio-sclerosis or atheroma. The affection known as *angina pectoris* (*q.v.*) may be a further consequence of this defective blood-supply.

The treatment varies according to the nature of the case. In serious cases of dilatation, rest in bed, purgatives and cardiac tonics will be required.

In commencing degenerative change the Oertel treatment, consisting of graduated exercise up a gentle slope, limitation of fluids and a special diet, may be indicated. In cases of slight dilatation after influenza or recent illness, the Schott treatment by baths and exercises as carried out at Nauheim is sometimes beneficial.

Disorders of Rhythm of the Heart's Action.—Under this heading may be grouped a number of conditions concerning which much has been learned during the past 20 years by the researches of the late Sir James Mackenzie and Sir Thomas Lewis. By means of Mackenzie's ink polygraph or Lewis's modification a prolonged simultaneous record of the arterial and venous pulses can be obtained.

Electrical Records.—Electrical records of the heart beat have given even more accurate results. It has long been known that a minute electrical current is generated when the heart, or any other muscle, contracts. In 1903 Einthoven, of Leyden, invented his string galvanometer (*q.v.*) an instrument capable of detecting a current of less than $\frac{1}{80000}$ millionth of an ampère. By putting the human heart in electrical connection with the instrument, either by means of contacts from the chest wall in front of the heart, or, more conveniently, by three electrodes in which the two hands and one foot are immersed, a graphic curve is obtained of the electrical variations associated with each heart beat together with appropriate time marks. On such a curve the variations due to auricular and ventricular contraction respectively are differentiated, the wave representing auricular contraction being designated arbitrarily as "P," and that representing the commencement of ventricular contraction "R." The time interval between these two components of each normal heart beat can be measured accurately.

Heart Block.—In health this time interval is between 0.18 to 0.20 sec.; if the junctional tissues between auricle and ventricle are injured, either by disease or by cardiac poisons, conduction between auricle and ventricle is delayed and the "P.R." interval may become 0.24 sec., or even more. This state of affairs is known as heart block, and in its minor stages can be recognized only by means of graphic records. With more severe damage of the junctional tissues, higher grades of auriculo-ventricular block ensue; thus the ventricle may respond only to every alternate, or to every third or fourth auricular beat. In complete heart block no stimuli reach ventricle from auricle and there is complete dissociation between the upper and lower chambers of the heart, the former beating at their usual rate of 60–80 per min. while the ventricles take on a rhythm of their own, usually at a rate of about 35–40. The presence of these more serious grades of heart block can often be surmised on clinical grounds, but graphic records are essential for their certain recognition. Heart block is one of the rarer causes of irregular heart action.

Other Features.—There are some other causes of cardiac arrhythmia, some of which are unimportant, others serious. Quite early in the century it was impossible to differentiate with certainty between the two types. Now differentiation can be made with confidence, and often without the necessity for taking polygraphic or electro-cardiographic tracings. For instance, "intermissions" of the pulse and "premature beats" were considered to be serious. Nowadays it is recognized that, in themselves, they are not serious but are almost invariably present from time to time in most elderly subjects.

Auricular Fibrillation.—But there is another common type of cardiac arrhythmia known as auricular fibrillation which is undoubtedly serious. Here, as a result of pathological changes in the heart muscle, the auricles cease to contract rhythmically as a whole in a series of orderly beats; but the auricular musculature is in a constant state of inco-ordinate and futile twitchings. In consequence, the ventricles, instead of being stimulated from above rhythmically at the rate of about 70 per min. are overwhelmed by a series of stimuli which pour down on them like an avalanche. They do their best to respond, and contract rapidly and irregularly at a rate of 120–180 per minute. This condition is

very constantly associated with cardiac failure, usually ending in dropsy, shortness of breath and eventually, if progressive, in death. It is a dangerous condition, but when recognized (and about its recognition there is now seldom any difficulty) it may be controlled by the administration of digitalis. This drug depresses the conductivity between auricle and ventricle, and consequently only the more powerful auricular stimuli reach the ventricle after its use; the ventricle now beats, still irregularly, but more slowly, and consequently, having time for a longer rest between each beat, more powerfully. The auricles may fibrillate in paroxysms lasting a few minutes, hours or days; but more commonly the condition is a permanent one. It brings about great disability, but, if controlled by the use of digitalis and if the patient is content to live within his limits, it is often compatible with 10, 15 or even 20 years of very fair health.

The Circus Movement.—Lewis has recently demonstrated by means of the string galvanometer that in auricular fibrillation, as in its sister condition, auricular flutter, instead of each auricular beat arising in the sinu-auricular node and radiating thence throughout the auricles, a "circus movement" takes place in the auricular muscle, often around the mouths of the great veins entering the right auricle. We have to conceive of an irregular wave of contraction whirling around, usually in an irregular circle. From this contractile path are projected into the surrounding auricular muscle countless stimulating impulses, very much as sparks are thrown out from a catherine wheel, and, as a result, the whole of the auricular musculature is thrown into incessant, shimmering contractions. So soon as this explanation of auricular fibrillation was put forward and accepted, it was manifest that, if we could bridge the gap between the advancing crest, and the retreating wake of the contracting wave in its "circus," the heart might revert to normal rhythm. It has been found that quinine and its allied alkaloids, of which quinidine is the one usually employed, have such an effect. In rather more than 50% of cases of auricular fibrillation it is possible to bring about a reversion to normal rhythm by the use of quinidine. Unfortunately the process is not devoid of risk, and many cases relapse into fibrillation when quinidine is withdrawn.

Paroxysmal Tachycardia.—Here the heart beats with great rapidity (rates of 150–200 per min.), but regularly. There is an abrupt transition from the normal and slow, to the abnormal and rapid rhythm; the attack may last for a few seconds, or for a few days, and ends as abruptly as it began. Such attacks may be associated with great respiratory and mental distress, and may lead to cardiac failure. Their differentiation from a purely nervous form of rapid heart action may be impossible without an electrocardiogram taken during both normal and abnormal periods.

Bradycardia.—In some healthy persons the rate of heart beat is unusually slow. In jaundice a slow pulse rate is the rule.

X-rays in Cardiology.—Of recent years X-rays have been used extensively in the investigation of cardiac disease. By their help alone can accurate information be obtained of the size of the heart and aorta. Percussion and location of the apex beat by the finger are often misleading.

Vital Capacity.—The vital capacity is the maximal amount of air which an individual can expire from the lungs after taking the deepest possible inspiration. Disease of either heart or lungs may very materially diminish this quantity which falls or rises according as the disease advances or tends to recovery. Estimation of the vital capacity, therefore, is a means of recording numerically a functional disability and its progress. The trend of recent instrumental investigation of the heart's action has been to stress the importance of the heart's muscle in cardiac pathology and to minimise the effect of valvular lesions, to which so much attention was formerly paid. Possibly the pendulum has swung a little too far in this direction but it is certain that many cardiac murmurs heard through the stethoscope are not necessarily indicative of valvular or of any other disease. The innocuous nature of these "exo-cardial," "cardio-respiratory," or "haemic" murmurs, had long been known to the more experienced physicians, but it required the mass experiment of the World War to teach the lesson to the rank and file of the profession.

In Dec. 1925 Yandel Henderson, of Yale university, published a comparatively simple method of determining the output of the heart per beat. From this it is easy to calculate the actual work done by the heart, and to recognize departures from normal efficiency. Thus we now appear to have a simple method of ascertaining with accuracy whether a heart is functioning normally or not, and whether a defect previously discovered is stationary, improving or deteriorating.

HEART AND LUNG, SURGERY OF. Surgery of the heart itself is of quite recent origin and has been mainly devoted to three subjects.

I. SURGERY OF THE HEART

Removal of Foreign Bodies Retained in the Heart Wall.

—The safety of the methods of surgical approach to the heart has been demonstrated. Surgeons in many countries have removed war missiles from the wall of the heart and from the pericardium with a surprisingly small mortality. R. le Fort (*Bull. et Mém. Acad. de Méd.*, vol. 80, p. 147, 1918) removed 11 foreign bodies from nine patients, with one death. Roberts successfully removed a bullet from the posterior wall of the left ventricle, which had been present for seven years and was causing cardiac disturbance. The approach by resection of one rib and traversing the pleura was excellent. He had also removed four fragments of shell from the pericardium in four patients by the same route, with no mortality.

Operations for Stenosis of the Valvular Orifices of the Heart.—A new field for surgery in the treatment of what has for long been a purely medical subject is being opened up by work which has hitherto been largely experimental. The subject is still in its infancy, but enough has been done to show that with further experience certain selected cases of mitral stenosis, in which the musculature of the heart has not been too much damaged, may be submitted to operation with a fair prospect of improvement. Duff S. Allen and E. A. Graham (*Jour. Amer. Med. Assoc.*, Sept. 23, 1922, and *Arch. of Surg.*, Jan. 1924) have invented an instrument which they call a cardioscope. This is a tube, closed at one end by a lens, which is introduced into the heart through a small incision. When the lens is pressed against the heart wall so that no blood intervenes, the endocardium, illuminated by a small electric bulb, is clearly visible. In the wall of the tube is fitted a rod ending in a small knife, with which a stenosed valve may be incised under direct vision. In dogs, when the incision to introduce the cardioscope was made in the auricular appendix, all the dogs recovered. E. C. Cutler and S. A. L. Levine (*The Boston Med. and Surg. Jour.*, June 28, 1923), believing that a mere incision in the stenosed ring will heal without relief of the stenosis, invented an instrument which punches out a piece of tissue.

They have used this successfully in the case of a girl, aged 12, suffering from mitral stenosis. She was alive 10 months later and was still improving. H. S. Souttar (*Brit. Med. Jour.*, Oct. 3, 1925) reports a brilliant operation on a girl of 15 with mitral stenosis and regurgitation. He exposed the heart by a flap operation, and placed a light clamp on the base of the auricular appendix. After two guide sutures had been inserted, the appendix was incised and drawn over the finger like a glove, haemorrhage being thus obviated. The interior of the auricle was easily explored by the finger, no effect on the pulse being noted. The blood pressure instantly fell to zero as the passage of blood through the orifice was abolished. Souttar intended to divide the stenosed orifice with a knife passed along the finger, but as the stenosis was found to be of moderate degree with little thickening of the valve, he contented himself with stretching the orifice with the finger. The appendage was ligated at its base and the wound of the chest wall closed. The patient's condition was improved and she was well three months later, though still somewhat breathless on exertion.

Cervical Sympathectomy for Angina Pectoris.—The cause of this very distressing disease is not settled with certainty. But as changes in the cardiac muscle, coronary arteries and aorta are usually present it may be considered.

Jonnesco, of Bucharest, in 1916 first performed the removal of the left cervical sympathetic chain, including the upper and middle cervical ganglia and the first thoracic ganglion. The result, followed for four years, was complete relief from symptoms. T. Jonnesco operates under spinal anaesthesia (*La Presse Méd.*, April 26, 1922). W. B. Coffey and P. K. Brown (*Arch. Int. Med.*, vol. 31, p. 200, 1923) report six cases with one death and great improvement in the other five. H. Lilienthal (*Arch. of Surg.*, vol. 10, p. 531, 1925) three cases. In one, the cervical sympathetic was removed on both sides. All were cured. H. H. Kerr (*Ann. of Surg.*, vol. 82, p. 354, 1925) reports five cases. He removes the superior cervical ganglion only, under local infiltration anaesthesia by novocain, and obtains the same results as the others by the more formidable operation performed by Jonnesco.

II. SURGERY OF THE LUNG

Since the World War the surgery of the lung has made great strides, and in all countries is engaging the attention of active workers. While differential pressure anaesthesia of some kind is still advisable, the introduction of intra-tracheal insufflation has enabled the elaborate and costly pressure chambers to be dispensed with. For many types of operation ordinary inhalation anaesthesia, especially by nitrous oxide and oxygen, suffices. Local infiltration anaesthesia, combined with nerve blocking by novocain or some similar drug, is largely used, and for some operations is essential. It is being combined with light analgesia by nitrous oxide and oxygen, or even ether by some surgeons in the case of nervous patients, for whom deep general anaesthesia is inadvisable (*see ANAESTHESIA AND ANAESTHETICS*).

Surgical Treatment of Pulmonary Tuberculosis.—Direct operations on the tuberculous lung, either by drainage of tuberculous cavities or the resection of one or more lobes of the lung, have been abandoned by the majority of thoracic surgeons. The great advance in latter years has been in devising methods of collapsing the affected lung either temporarily or permanently.

Principles of Collapse Therapy.—In all other parts of the body it is found that rest of the affected part is beneficial, but in the case of the lung the respiratory movements, exaggerated by coughing, continue unless the lung is compressed. By collapse, stasis in the lymphatic vessels occurs, preventing spread of tubercle bacilli to other parts of the lung and diminishing the entrance of toxins into the general circulation with consequent improvement of the general resistance of the body. Congestion of the collapsed lung with blood appears to occur, favouring the formation of fibrous tissue and healing of the lesions. Mechanically, the effect is to allow the retraction of the new formed fibrous tissue and to collapse cavities and dilated bronchi. This prevents the retention of secretions, which often become secondarily infected with other organisms, and allows the walls of the cavities to come in contact and so to heal. This retraction occurs normally to a limited extent by the pulling up of the diaphragm, the pulling over of the mediastinum, and the assumption of the expiratory position by the ribs, but falls far short of that necessary for complete obliteration of the cavities.

Methods of Producing Collapse.—Artificial pneumothorax was first proposed by James Carson, of Liverpool, in 1821, but was introduced into practice by Forlanini, of Pavia, in 1882 (*Gazz. d. Osp.*, 1882). It is now extensively practised by physicians all over the world. By the introduction of air, oxygen or nitrogen through a hollow needle into the pleural cavity the lung may be more completely collapsed than by any other method. As this method is simple and satisfactory it is the method of choice, and other operations are only undertaken when this is impossible, through the presence of adhesions binding the two layers of the pleura together (*see PNEUMOTHORAX*).

Division of Adhesions.—Where the adhesions are few and bandlike, so that a partial collapse only can be obtained, it is necessary to divide them. The operation of thoracotomy and division of the bands by direct vision is unnecessarily severe. Jacobaeus, of Stockholm, in 1913 devised an instrument similar to a cystoscope, which he calls a thoracoscope. After the induction of a pneumothorax this is introduced under novocain anaesthesia

through a canula. Through a smaller canula a galvanocautery is introduced. Thus the adhesions may be burnt through under the vision of the operator without opening the chest cavity (H. C. Jacobaeus, *Proc. Roy. Soc. Med.*, 1922-23, vol. 16, p. 45). By using the cautery at a red heat only, haemorrhage is avoided. The adhesions often pull out a cone of lung substance in which may be a prolongation of a lung cavity, so that it is important to burn the adhesions through as near the chest wall as possible.

Paralysis of the Diaphragm.—Stuertz first proposed this operation by division of the phrenic nerve in the neck, which was independently devised by Sauerbruch. The result of depriving the diaphragm on one side of its motor innervation is that it rises in the thorax as much as $2\frac{1}{2}$ to 3 in., thus allowing the lower lobe partially to collapse and putting it at rest. The operation is easily done in a few minutes under local anaesthesia by novocain, the nerve being found running obliquely across the scalenus anticus muscle in the neck. At first the nerve was simply divided, but it was found that accessory fibres joined it below the point of section in 20-30% of individuals. W. Felix's operation of "Exairesis" (*Deutsch. Ztsch. f. Chir.*, No. 171, p. 283, 1922) has gained favour. In this modification the lower end of the divided nerve is seized in forceps and gradually drawn out of the thorax. Sometimes the whole length of the nerve as far as the diaphragm is successfully extracted, but in any case the collaterals which join it in its upper part are also severed so that the paralysis is complete. The operation is used where basal adhesions are preventing full collapse in pneumothorax, as an addition to thoracoplasty, in some cases of early tuberculosis of the lower lobe only and for the relief of pain in the region of the diaphragm on coughing.

Extrapleural Pneumolysis.—The operation consists in separating the parietal layer of the pleura from the chest wall over a limited area and filling the space thus formed with some material which is not absorbed, thereby compressing the lung beneath. A portion of one rib is resected and the posterior periosteum and endothoracic fascia are carefully incised. The gloved finger then separates the outer surface of the parietal pleura from the inner surface of the endothoracic fascia. As the air which enters the cavity thus formed is rapidly absorbed it is necessary to provide some filling. Tuffier, in 1910, first used fat obtained from omentum or a lipoma. This has become one of the favourite methods, the fat being obtained from the patient's thigh (Tuffier, *Bull. et. mém. Soc. de Chir. de Paris*, vol. 49, 1249, 1923). If a very careful aseptic technique is not followed the fat may be extruded. Owing to the difficulty of obtaining enough fat, Baer, in 1913, used a paraffin filling (H. Baer, *Munch. med. Wochenschr.*, vol. 68, 1921). This is readily available but is heavy, and tends to be extruded later in many cases. E. W. Archibald, of Montreal (*Am. Rev. of Tuberc.*, vol. 4, p. 828, 1921), has used a pedicled muscle graft obtained by detaching the pectoral muscle.

The operation is almost confined to apical lesions and is used either alone, or following thoracoplasty, in cases where the apex of the lung is incompletely collapsed. It may also be of service where the apex alone is adherent and a satisfactory pneumothorax has collapsed the lower part of the lung.

Extrapleural Thoracoplasty.—Collapsing operations on the chest wall were suggested as long ago as 1888 (Quincke) and 1890 (Spengler). In 1907 Brauer and Friedreich removed large portions of the ribs in their lateral portions. Wilms, in 1911, removed portions both posteriorly and anteriorly. The modern operation of paravertebral thoracoplasty is due to Sauerbruch and the Scandinavians: Bull, of Oslo; Saugman, of Veilefjord; Jacobaeus and Key, of Stockholm. The operation may be done in one, two or more stages and consists essentially in resecting a portion of the first to the 10th or 11th ribs posteriorly through a long incision posterior to the scapula and turning forwards along the 10th rib. The muscles attached to the scapula are divided and the scapula is turned forwards. It is essential that the ribs should be resected as far back as the tips of the transverse processes of the vertebrae. The length of rib removed varies from $\frac{1}{2}$ in. of the first rib to 7 or 8 in. of the middle and lower ones. The operation is a severe one, but the mortality, which was at first about 8%, has been reduced by proper selection of cases to

about 2% in the hands of experienced operators. Many operators still prefer a local anaesthesia by novocain, but the tendency now, except in cases with profuse sputum, is to operate under general anaesthesia by nitrous oxide and oxygen preceded by an injection of morphine and hyoscine. The results of these operations have shown that in cases of unilateral or mainly unilateral pulmonary tuberculosis which are not improving under sanatorium treatment a new field of hope is opening out. F. Sauerbruch (*Chir. der Brustorgane*, 1920), H. C. Jacobaeus and E. Key (*Acta Chir. Scand.*, 1923); P. Bull (*Proc. Roy. Soc. Med.*, 1924, vol. 17, p. 1); J. Alexander (*Surg. of Pulmon. Tub.*, 1925); J. Gravesen (*Surg. Treat. of Pulmon. and Pleur. Tub.*, 1925).

Bronchiectasis.—Three types of operation are used in the treatment of this distressing condition: (1) Drainage operations, (2) operations to collapse the lungs, (3) radical excision of the affected part of the lung. (1) Drainage operations are palliative only and aim either at drainage of abscess cavities or, by making a permanent bronchial fistula, at reducing the amount of sputum. (2) All the forms of collapsing operations which are in use for pulmonary tuberculosis have their place in the treatment of bronchiectasis. They are phrenicotomy, pneumothorax, extrapleural pneumolysis and extrapleural thoracoplasty. The principles involved are, firstly, that the spaces in which secretions collect and decompose are obliterated by the collapse of the lung, and secondly that the new formed fibrous tissue in its contraction no longer pulls open the walls of the bronchi softened by inflammation, but can now pull inward the mobilised walls of the thorax. (3) In certain types of bronchiectasis the results of collapsing operations are not satisfactory, and in consequence amputation of the affected lobe or lobes of the lung has been performed. This procedure has produced real cures but the mortality of the operation is high. The longest series of cases is that published by H. Lillenthal, of New York (*Arch. of Surg.*, vol. 8, 1924), whose mortality is nearly 50%. Many of his patients were, however, desperately ill. Everts A. Graham (*Arch. of Surg.*, vol. 10, p. 392, 1925) has practised pneumectomy by the actual cautery, in one or several stages, on 20 patients. Of these, 50% were cured, 30% improved and 20% died.

Intrathoracic Tumours.—Innocent intrathoracic tumours are being diagnosed with greater frequency owing to the increasing use of X-rays. H. C. Jacobaeus and E. Key (*Acta Chir. Scand.*, vol. 53, p. 575, 1921) have successfully removed four fibromata by the transpleural route. T. P. Dunhill (*Br. Jour. of Surg.*, 1922) removed a fibroma by Gask's modified sternum splitting operation. J. E. H. Roberts (*Tr. Roy. Soc. Med.*, 1926) has removed four innocent tumours, two fibromas, an encapsuled endothelioma and a dermoid cyst, three by the transpleural route and one by sternum splitting.

Malignant Tumours of the Lung.—Radical operations for the removal of carcinomata of the lung are rarely possible owing to the later stage at which patients come under observation. F. Sauerbruch (*Chir. der Brustorgane*) has operated in five cases: One with a carcinoma of the lower lobe the size of a small fist, was alive five years later; another was alive after three years. Sauerbruch advises a two-stage operation or three-stage operation, ligature of the branch of the pulmonary artery to the affected lobe being done as a preliminary followed by thoracoplasty and resection of lung.

Palliative operations often give great relief from distressing symptoms and prolong life for many months; they are (1) drainage of a secondary lung abscess or empyema, (2) drainage of a sterile abscess due to necrosis of growth, (3) exposure of the growth for the insertion of radium, (4) treatment by X-rays.

HEART-BURIAL, the burial of the heart apart from the body. The practice began very early in ancient Egypt and in mediaeval Europe heart-burial was fairly common. Some of the more notable cases are those of Richard I., whose heart, preserved in a casket, was placed in Rouen cathedral; of Henry III., buried in Normandy; and of Edward I., at Jerusalem. Since the 17th century the hearts of deceased members of the house of Habsburg have been buried apart from the body in the Loretto chapel in the Augustiner Kirche, Vienna. The most romantic story of heart-burial is that of Robert Bruce. He wished his heart to rest at Jerusalem in the Church of the Holy Sepulchre, and on his death-bed entrusted the fulfilment of his wish to Douglas. The latter broke his journey to join the Spaniards in their war with the Moorish king of Granada, and was killed in battle, the heart of Bruce enclosed in a silver casket hanging round his neck. Subsequently the heart was buried at Melrose abbey. Of notable 17th century cases there is that of James II., whose heart was buried in the church of the Convent of the Visitation at Chaillot near Paris, and that of Sir William Temple, at Moor Park, Farnham. The last ceremonial burial of a heart in England was that of Paul Whitehead, secretary to the Monks of Medmenham club, in 1775, the interment taking place in Le Despenser mausoleum at High Wycombe, Bucks. Of later cases the most notable are those of Daniel O'Connell, whose heart is at Rome, Shelley's at Bournemouth, Kosciusko's at the Polish museum at Rapperschwyll, Lake Zürich, and the marquess of Bute, taken by his widow to Jerusalem for burial in 1900; Thomas Hardy's heart was buried in his first wife's grave at Stinsford, Dorset, in Jan. 1928. The viscera of the popes from Sixtus V. (1590) onward have been preserved in the parish church of the Quirinal.

See Pettigrew, *Chronicles of the Tombs* (1857).

HEARTH, the part of a room where a fire is made, also the fire and cooking apparatus on board ship; the floor of a smith's forge, or of a reverberatory furnace on which the ore is exposed to the flame; the lower part of a blast furnace through which the metal goes down into the crucible; in soldering, a portable brazier or chafing dish, and an iron box sunk in the middle of a flat iron plate or table. An "open-hearth furnace" is a regenerative furnace of the reverberatory type used in making steel, hence "open-hearth steel" (see IRON and STEEL).

HEARTH TAX. This impost, also known as hearth-money or chimney-money, was a tax imposed in England at a rate of 2s. for each hearth; it was levied upon all houses except cottages. It was first levied in 1662, but owing to its unpopularity, chiefly caused by the domiciliary visits of the collectors, it was repealed in 1689, although it was producing £170,000 a year. The principle of the tax was not new in the history of taxation, for in Anglo-Saxon times the king derived a part of his revenue from a *fumage*, or tax of smoke, levied on all hearths except those of the poor. It appears also in the hearth-penny or tax of a penny on every hearth, which as early as the 10th century was paid annually to the pope. (See PETER'S PENCE.)

HEARTS, a game of cards of recent origin, though founded upon the same principle as many old games, such as *Slobberhannes*, *Four Jacks* and *Enflé*, namely, that of losing instead of winning as many tricks as possible. Hearts is played with a full pack, ace counting highest and deuce lowest. In the four-handed game, which is usually played, the entire pack is dealt out as at whist (but without turning up the last card, since there are no trumps), and the player at the dealer's left begins by leading any card he chooses, the trick being taken by the highest card of the suit led. Each player must follow suit if he can; if he has no cards of the suit led he is privileged to throw away any card he likes, thus having an opportunity of getting rid of his hearts, which is the object of the game. When all thirteen tricks have been played each player counts the hearts he has taken in and pays into the pool a certain number of counters for them, according to an arrangement made before beginning play. In the four-handed, or sweep-stake, game the method of settling called "Howell's," from the name of the inventor, has been generally adopted, according to which each player begins with an equal number of chips, say 100, and after the hand has been played pays into the pool as

many chips for each heart he has taken as there are players besides himself. Then each player takes out of the pool one chip for every heart he did not win. The pool is thus exhausted with every deal. Hearts may be played by two, three, four or even more players, each playing for himself.

Spot Hearts.—In this variation the hearts count according to the number of spots on the cards, excepting that the ace counts 14, the king 13, queen 12 and knave 11, the combined score of the thirteen hearts being thus 104.

Auction Hearts.—In this the eldest hand examines his hand and bids a certain number of counters for the privilege of naming the suit to be got rid of, but without naming the suit. The other players in succession have the privilege of outbidding him, and whoever bids most declares the suit and pays the amount of his bid into the pool, the winner taking it.

Joker Hearts.—Here the deuce of hearts is discarded, and an extra card, called the joker, takes its place, ranking in value between ten and knave. It cannot be thrown away, excepting when hearts are led and an ace or court card is played, though if an opponent discards the ace or a court card of hearts then the holder of the joker may discard it. The joker is usually considered worth five chips, which are either paid into the pool or to the player who succeeds in discarding the joker.

Heartsette.—In this variation the deuce of spades is deleted and the three cards left after dealing twelve cards to each player are called the *widow* (or *kitty*), and are left face downward on the table. The winner of the first trick must take the widow without showing it to his opponents.

Slobberhannes.—The object of this older form of Hearts is to avoid taking either the first or last trick or a trick containing the queen of clubs. A euchre pack (thirty-two cards, lacking all below the 7) is used, and each player is given ten counters, one being forfeited to the pool if a player takes the first or last trick, or that containing the club queen. If he takes all three he forfeits four points.

Four Jacks (Polignac or Quatre-Valets) is usually played with a piquet pack, the cards ranking in France as at *écarté*, but in Great Britain and America as at piquet. There is no trump suit. Counters are used, and the object of the game is to avoid taking any trick containing a knave, especially the knave of spades, called *Polignac*. The player taking such a trick forfeits one counter to the pool.

Enfilé (or Schwellen) is usually played by four persons with a piquet pack and for a pool. The cards rank as at Hearts, and there is no trump suit. A player must follow suit if he can, but if he cannot he may not discard, but must take up all tricks already won and add them to his hand. Play is continued until one player gets rid of all his cards and thus wins.

HEARTS OF OAK BENEFIT SOCIETY: see FRIENDLY SOCIETIES.

HEAT, a general term applied to that branch of physical science which deals with the effects produced by heat on material bodies, with the laws of transference of heat, and with the transformations of heat into other kinds of energy. The object of the present article is to give a brief sketch of the historical development of the science of heat, and to indicate the relation of the different branches of the subject, which are discussed in greater detail with reference to the latest progress in separate articles.

1. The term heat is employed in ordinary language in a number of different senses. This makes it a convenient term to employ for the general title of the science, but the different meanings must be carefully distinguished in scientific reasoning. For the present purpose, omitting metaphorical significations, we may distinguish four principal uses of the term:—(a) sensation of heat; (b) temperature, or degree of hotness; (c) quantity of thermal energy; (d) radiant heat, or energy of radiation.

(a) From the sense of heat, aided in the case of very hot bodies by the sense of sight, we obtain our first rough notions of heat as a physical entity, which alters the state of a body and its condition in respect of warmth, and is capable of passing from one body to another. By touching a body we can tell whether it is warmer or

colder than the hand, and, by touching two similar bodies in succession, we can form a rough estimate, by the acuteness of the sensation experienced, of their difference in hotness or coldness over a limited range. If a hot iron is placed on a cold iron plate, we may observe that the plate is heated and the iron cooled until both attain appreciably the same degree of warmth; and we infer from similar cases that something which we call "heat" tends to pass from hot to cold bodies, and to attain finally a state of equable diffusion when all the bodies concerned are equally warm or cold. Ideas such as these derived entirely from the sense of heat, are, so to speak, embedded in the language of every nation from the earliest times.

(b) From the sense of heat, again, we naturally derive the idea of a continuous scale or order, expressed by such terms as summer heat, blood heat, fever heat, red heat, white heat, in which all bodies may be placed with regard to their degrees of hotness, and we speak of the *temperature* of a body as denoting its place in the scale, in contradistinction to the quantity of heat it may contain.

(c) The quantity of heat contained in a body obviously depends on the size of the body considered. Thus a large kettleful of boiling water will evidently contain more heat than a teacupful, though both may be at the same temperature. The temperature does not depend on the size of the body, but on the degree of concentration of the heat in it, *i.e.*, on the quantity of heat per unit mass, other things being equal.

It may be taken as axiomatic that a given body in a given state under given conditions (*e.g.*, a pound of water in the liquid state at freezing point under atmospheric pressure) must always contain the same quantity of heat, and that different quantities of the same substance in the same state under the same conditions must contain quantities of heat proportional to their several masses. But it is for experiment to determine how the heat-content varies for any given substance in different states, or for different substances in similar states, and how it is affected by variations of temperature and pressure in each case.

(d) It is a matter of common observation that rays of the sun or of a fire falling on a body warm it, and it was in the first instance natural to suppose that heat itself somehow travelled across the intervening space from the sun or fire to the body warmed, in much the same way as heat may be carried by a current of hot air or water. But we now know that energy of radiation is not the same thing as heat, though it is converted into heat when the rays strike an absorbing substance. The term "radiant heat," however, is generally retained, because radiation is commonly measured in terms of the heat it produces, and because the transference of energy by radiation and absorption is the most important agency in the diffusion of heat.

TEMPERATURE

2. **Evolution of the Thermometer.**—The first step in the development of the science of heat was necessarily the invention of a thermometer, an instrument for indicating temperature and measuring its changes. The first requisite in the case of such an instrument is that it should always give, at least approximately the same indication at the same temperature. The air-thermoscope of Galileo, illustrated in fig. 1, which consisted of a glass bulb containing air, connected to a glass tube of small bore dipping into a coloured liquid, though very sensitive to variations of temperature, was not satisfactory as a measuring instrument, because it was also affected by variations of atmospheric pressure. The French doctor Rey describes in a letter dated 1631 a thermometer in which the expansion of water itself was used to indicate temperature, but it is not clear from his description whether the thermometer tube was left open or closed.

FIG. 1.—GALILEO'S AIR THERMOSCOPE

The type of thermometer familiar at the present time, containing a liquid hermetically sealed in a glass bulb with a fine tube attached, was first brought into general use by the Grand Duke

Ferdinand II. of Tuscany, and he is said to have possessed such instruments as early as 1654. They were much employed by the members of the *Accademia del Cimento* founded under his protection at Florence, and were long known as Florentine thermometers. Alcohol was the liquid first employed, and the degrees, intended to represent thousandths of the volume of the bulb, were marked with small beads of enamel fused on the stem, as shown in fig. 2, which represents two thermometers as depicted in the *Saggi di Naturali Esperienze* published by the *Accademia del Cimento* in 1666.

FIG. 2.—EARLY FLORENTINE THERMOMETERS, 1666
Alcohol in glass, graduated with enamel beads on stem

In order to render the readings of such instruments comparable with each other, it was necessary to select a fixed point or standard temperature as the zero or starting point of the graduations. Instead of making each degree a given fraction of the volume of the bulb, which would be difficult in practice, and would give different values for the degree with different liquids, it was soon found to be preferable to take two fixed points, and to divide the interval between them into the same number of degrees. It was natural in the first instance to take the temperature of the human body as one of the fixed points. In 1701 Sir Isaac Newton proposed a scale in which the freezing-point of water was taken as zero, and the temperature of the human body as 12° . About the same date (1714) Gabriel Daniel Fahrenheit proposed to take as zero the lowest temperature obtainable with a freezing mixture of ice and salt, and to divide the interval between this temperature and that of the human body into 12° . To obtain finer graduations the number was subsequently increased to 96° .

The freezing-point of water was at that time supposed to be somewhat variable, because as a matter of fact it is possible to cool water several degrees below its freezing-point in the absence of ice. Fahrenheit showed, however, that as soon as ice began to form the temperature always rose to the same point, and that a mixture of ice or snow with pure water always gave the same temperature. At a later period he also showed that the temperature of boiling water varied with the barometric pressure, but that it was always the same at the same pressure, and might therefore be used as the second fixed point (as Edmund Halley and others had suggested) provided that a definite pressure, such as the average atmospheric pressure, were specified. The freezing and boiling-points on one of his thermometers, graduated as already explained, with the temperature of the body as 96° , came out in the neighbourhood of 32° and 212° respectively, giving an interval of 180° between these points. Shortly after Fahrenheit's death (1736) the freezing and boiling-points of water were generally recognized as the most convenient fixed points to adopt, but different systems of subdivision were employed. Fahrenheit's scale, with its small degrees and its zero below the freezing-point, possesses undoubted advantages for meteorological work, and is still retained in most English-speaking countries. For general scientific purposes, however, the centigrade system, in which the freezing-point is marked 0° and the boiling-point 100° , is now almost universally employed, on account of its greater simplicity from an arithmetical point of view. For work of precision the fixed points have been more exactly defined (see THERMOMETRY), but no change has been made in the fundamental principle of graduation.

3. **Comparison of Scales Based on Expansion.**—Thermometers constructed in the manner already described will give strictly comparable readings, provided that the tubes be of uniform bore, and that the same liquid and glass be employed in their construction; but they possess one obvious defect from a theoretical point of view, namely, that the subdivision of the temperature scale depends on the expansion of the particular liquid selected as the standard. A liquid such as water, which, when continuously heated at a uniform rate from its freezing-point, first contracts and then expands, at a rapidly increasing rate, would

obviously be unsuitable; but there is no a priori reason why other liquids should not behave to some extent in a similar way. As a matter of fact, it was soon observed that thermometers carefully constructed with different liquids, such as alcohol, oil and mercury, did not agree precisely in their indications at points of the scale intermediate between the fixed points, and diverged even more widely outside these limits. Another possible method, proposed in 1694 by Carlo Renaldini (1615–1698), professor of mathematics and philosophy at Pisa, would be to determine the intermediate points of the scale by observing the temperatures of mixtures of ice-cold and boiling water in varying proportions. By this method, the temperature of 50° C would be defined as that obtained by mixing equal weights of water at 0° C and 100° C; 20° C, that obtained by mixing 80 parts of water at 0° C with 20 parts of water at 100° C and so on. Each degree rise of temperature in a mass of water would then represent the addition of the same quantity of heat. The scale thus obtained would, as a matter of fact, agree very closely with that of a mercury thermometer, but the method would be very difficult to put in practice, and would still have the disadvantage of depending on the properties of a particular liquid, namely, water, which is known to behave in an anomalous manner in other respects.

At a later date, the researches of Gay-Lussac (1802) and Regnault (1847) showed that the laws of the expansion of gases are much simpler than those of liquids. Whereas the expansion of alcohol between 0° C and 100° C is nearly seven times as great as that of mercury, all gases (excluding easily condensable vapours) expand equally, or so nearly equally that the differences between them cannot be detected without the most refined observations. This equality of expansion affords a strong a priori argument for selecting the scale given by the expansion of a gas as the standard scale of temperature, but there are still stronger theoretical grounds for this choice, which will be indicated in discussing the absolute scale (§ 23). Among liquids mercury is found to agree most nearly with the gas scale, and is generally employed in thermometers for scientific purposes on account of its high boiling-point and for other reasons. The differences of the mercurial scale from the gas scale having been carefully determined, the mercury thermometer can be used as a secondary standard to replace the gas thermometer within certain limits, as the gas thermometer would be very troublesome to employ directly in ordinary investigations. For certain purposes, and especially at temperatures beyond the range of mercury thermometers, electrical thermometers, also standardized by reference to the gas thermometer, have been very generally employed in recent years, while for still higher temperatures beyond the range of the gas thermometer, thermometers based on the recently established laws of radiation are the only instruments available. For a further discussion of the theory and practice of the measurement of temperature, the reader is referred to the article THERMOMETRY.

CHANGE OF STATE

4. Among the most important effects of heat is that of changing the state of a substance from solid to liquid, or from liquid to vapour. All substances, with the exception of some unstable compounds, are known to be capable of existing in each of the three states under suitable conditions of temperature and pressure. The transition of any substance, from the state of liquid to that of solid or vapour under the ordinary atmospheric pressure, takes place at fixed temperatures, the freezing and boiling-points, which are very sharply defined for pure crystalline substances, and serve in fact as fixed points of the thermometric scale. A change of state cannot, however, be effected in any case without the addition or subtraction of a certain definite quantity of heat. If a piece of ice below the freezing-point is gradually heated at a uniform rate, its temperature may be observed to rise regularly till the freezing-point is reached. At this point it begins to melt, and its temperature ceases to rise. The melting takes a considerable time, during the whole of which heat is being continuously supplied without producing any rise of temperature, although if the same quantity of heat were supplied to an equal mass of water, the

temperature of the water would be raised to the extent of nearly 80°C .

Heat thus absorbed in producing a change of state without rise of temperature is called *latent heat*, a term introduced by Joseph Black, who was one of the first to study the subject of change of state from the point of view of heat absorbed, and who in many cases actually adopted the comparatively rough method described above of estimating quantities of heat by observing the time required to produce a given change when the substance was receiving heat at a steady rate from its surroundings. For every change of state a definite quantity of heat is required, without which the change cannot take place. Heat must be added to melt a solid, or to vaporize a solid or a liquid, and conversely, heat must be subtracted to reverse the change, *i.e.*, to condense a vapour or freeze a liquid. The quantity required for any given change depends on the nature of the substance and the change considered, and varies to some extent with the conditions under which the change is made, but is always the same for the same change under the same conditions. A rough measurement of the latent heat of steam was made as early as 1764 by James Watt, who found that steam at 212°F , when passed from a kettle into a jar of cold water, was capable of raising nearly six times its weight of water to the boiling point. He gives the volume of the steam as being approximately 1,800 times that of an equal weight of water.

5. **General Phenomena of Fusion.**—There are two chief varieties of the process of fusion, namely, crystalline and amorphous, which are in many ways distinct, although it is possible to find intermediate cases which partake of the characteristics of both. The melting of ice may be taken as a typical case of crystalline fusion. The passage from rigid solid to mobile liquid occurs at a definite surface without any intermediate stage or plastic condition. The change takes place at a definite temperature, the fusing or freezing point (abbreviated F.P.), and requires the addition of a definite quantity of heat to the solid, which is called the latent heat of fusion. There is also in general a considerable change of volume during fusion, which amounts in the case of ice to a contraction of 9%.

Some typical cases of amorphous solidification are those of silica, glass, plastic sulphur, pitch, alcohol and many organic liquids. In this type the liquid gradually becomes more and more viscous as the temperature falls, and ultimately attains the rigidity characteristic of a solid, without any definite freezing point or latent heat. The condition of the substance remains uniform throughout, if its temperature is uniform; there is no separation into the two distinct phases of solid and liquid, and there is no sudden change of volume at any temperature.

The melting or freezing of a pure crystalline solid is characterized most clearly by the perfect constancy of temperature during the process. In fact, the law of constant temperature, which is generally stated as the first of the so-called "laws of fusion," does not strictly apply except to this case. The constancy of the F.P. of a pure substance is so characteristic that change of the F.P. is often one of the most convenient tests of the presence of foreign material. In the case of substances like ice, which melt at a low temperature and are easily obtained in large quantities in a state of purity, the point of fusion may be very accurately determined by observing the temperature of an intimate mixture of the solid and liquid while slowly melting as it absorbs heat from surrounding bodies. In the majority of cases, however, it is more convenient to observe the freezing point as the liquid is cooled. By this method it is possible to ensure perfect uniformity of temperature throughout the mass by stirring the liquid continuously during the process of freezing, whereas it is difficult to ensure uniformity of temperature in melting a solid, however gradually the heat is supplied, unless the solid can be mixed with the liquid. It is also possible to observe the F.P. in other ways, as by noting the temperature at the moment of the breaking of a wire, of the stoppage of a stirrer, or of the maximum rate of change of volume, but these methods are generally less certain in their indications than the point of greatest constancy of temperature in the case of homogeneous crystalline solids.

Fusing Points of Common Metals in $^{\circ}\text{C}$

Mercury	38.8	Antimony	630
Potassium	62.5	Aluminium	655
Sodium	97.6	Silver	962
Tin	231.9	Gold	1064
Bismuth	269.2	Copper	1082
Cadmium	320.7	Nickel	1452
Lead	327.7	Palladium	1556
Zinc	419.0	Platinum	1756

The table contains some of the most recent values of fusing points of metals determined (except the last three) with platinum thermometers. These points are often utilized as fixed points on the thermometric scale, especially for the calibration of thermocouples.

6. **Superfusion, Supersaturation.**—It is generally possible to cool a liquid several degrees below its normal freezing point without a separation of crystals, especially if it is protected from agitation, which would assist the molecules to rearrange themselves. A liquid in this state is said to be "undercooled" or "superfused." The phenomenon is even more familiar in the case of solutions (*e.g.*, sodium sulphate or acetate) which may remain in the "metastable" condition for an indefinite time if protected from dust. The introduction into the liquid under this condition of the smallest fragment of the crystal, with respect to which the solution is supersaturated, will produce immediate crystallization, which will continue until the temperature is raised to the saturation point by the liberation of the latent heat of fusion. The constancy of temperature at the normal freezing point is due to the equilibrium of exchange existing between the liquid and solid. Unless both solid and liquid are present, there is no condition of equilibrium, and the temperature is indeterminate.

It has been shown by H. A. Miers (*Jour. Chem. Soc.*, 1906) that for a supersaturated solution in metastable equilibrium there is an inferior limit of temperature, at which it passes into the "labile" state, *i.e.* spontaneous crystallization occurs throughout the mass in a fine shower. This seems to be analogous to the fine misty condensation which occurs in a supersaturated vapour in the absence of nuclei (*see* VAPORIZATION) when the supersaturation exceeds a certain limit.

7. **Freezing of Solutions and Alloys.**—The phenomena of freezing of crystalline mixtures may be illustrated by the case of aqueous solutions and of metallic solutions or alloys, which have been most widely studied. The usual effect of an impurity, such as salt or sugar in solution in water, is to lower the freezing point, so that no crystallization occurs until the temperature has fallen below the normal F.P. of the pure solvent, the depression of F.P. being nearly proportional to the concentration of the solution. When freezing begins, the solvent generally separates out from the solution in the pure state. This separation of the solvent involves an increase in the strength of the remaining solution, so that the temperature does not remain constant during the freezing, but continues to fall as more of the solvent is separated. There is a perfectly definite relation between temperature and concentration, at each stage of the process, which may be represented in the form of a curve as *AC* in fig. 3, called the freezing point curve.

The equilibrium temperature, at the surface of contact between the solid and liquid, depends only on the composition of the liquid phase and not at all on the quantity of solid present. The abscissa of the F.P. curve represents the composition of that portion of the original solution which remains liquid at any temperature. If instead of starting with a dilute solution we start with a strong solution represented by a point *N*, and cool it as shown by the vertical line *ND*, a point *D* is generally reached at which the solution becomes "saturated." The dissolved substance or "solute" then separates out as the solution is further cooled, and the concentration diminishes with fall of temperature in a definite relation, as indicated by the curve *CB*, which is called the solubility curve. Though often called by different names, the two curves *AC* and *CB* are essentially of a similar nature. To take the case of an aqueous solution of salt as an example, along *CB* the solution is saturated with respect to salt, along *AC* the solution is saturated with respect to ice. When the point *C* is reached along either

curve, the solution is saturated with respect to both salt and ice. The concentration cannot vary further, and the temperature remains constant, while the salt and ice crystallize out together, maintaining the exact proportions in which they exist in the solution. The resulting solid was termed a cryohydrate by F. Guthrie, but it is really an intimate mixture of two kinds of crystals, and not a chemical compound or hydrate containing the constituents in chemically equivalent proportions. The lowest temperature attainable by means of a freezing mixture is the temperature of the F.P. of the corresponding cryohydrate. In a mixture of salt and ice with the least trace of water a saturated brine is quickly formed, which dissolves the ice and falls rapidly in temperature, owing to the absorption of the latent heat of fusion. So long as both ice and salt are present, if the mixture is well stirred, the solution must necessarily become saturated with respect to both ice and salt, and this can only occur at the cryohydric temperature, at which the two curves of solubility intersect.

FIG. 3.—F.P., OR SOLUBILITY CURVE: SIMPLE CASE

The curves in fig. 3 also illustrate the simplest type of freezing point curve in the case of alloys of two metals *A* and *B* which do not form mixed crystals or chemical compounds. The alloy corresponding to the cryohydrate, possessing the lowest melting point, is called the eutectic alloy, as it is most easily cast and worked. It generally possesses a very fine-grained structure, and is not a chemical compound. (See ALLOYS.)

8. **Calorimetry by Latent Heat.**—In principle, the simplest and most direct method of measuring quantities of heat consists in observing the effects produced in melting a solid or vaporizing a liquid. It was, in fact, by the fusion of ice that quantities of heat were first measured. If a hot body is placed in a cavity in a block of ice at 0°C , and is covered by a closely fitting slab of ice, the quantity of ice melted will be directly proportional to the quantity of heat lost by the body in cooling to 0°C . None of the heat can possibly escape through the ice, and conversely no heat can possibly get in from outside. The body must cool exactly to 0°C , and every fraction of the heat it loses must melt an equivalent quantity of ice. Apart from heat lost in transferring the heated body to the ice block, the method is theoretically perfect. The only difficulty consists in the practical measurement of the quantity of ice melted. Black estimated this quantity by mopping out the cavity with a sponge which was weighed before and after the operation. But there is a variable film of water adhering to the walls of the cavity, which gives trouble in accurate work.

In 1780 Laplace and Lavoisier used a double-walled metallic vessel containing broken ice, which was in many respects more convenient than the block, but aggravated the difficulty of the film of water adhering to the ice. In spite of this practical difficulty, the quantity of heat required to melt unit weight of ice was for a long time taken as the unit of heat. This unit possesses the great advantage that it is independent of the scale of temperature adopted. At a much later date R. Bunsen (*Phil. Mag.*, 1871), adopting a suggestion of Sir John Herschel's, devised an ice-calorimeter suitable for measuring small quantities of heat, in which the difficulty of the water film was overcome by measuring the change in volume due to the melting of the ice. The volume of unit mass of ice is approximately 1.0920 times that of unit mass of water, so that the diminution of volume is 0.092 of a cubic centimetre for each gramme of ice melted. The method requires careful attention to details of manipulation, which are more fully discussed in the article on CALORIMETRY.

For measuring large quantities of heat, such as those produced by the combustion of fuel in a boiler, the most convenient method is the evaporation of water, which is commonly employed by engineers for the purpose. The natural unit in this case is the quantity of heat required to evaporate unit mass of water at the boiling

point under atmospheric pressure. In boilers working at a higher pressure, or supplied with water at a lower temperature, appropriate corrections are applied to deduce the quantity evaporated in terms of this unit.

For laboratory work on a small scale the converse method of condensation has been successfully applied by John Joly, in whose steam-calorimeter the quantity of heat required to raise the temperature of a body from the atmospheric temperature to that of steam condensing at atmospheric pressure is observed by weighing the mass of steam condensed on it. (See CALORIMETRY.)

9. **Thermometric Calorimetry.**—For the majority of purposes the most convenient and the most readily applicable method of measuring quantities of heat, is to observe the rise of temperature produced in a known mass of water contained in a suitable vessel or calorimeter. This method was employed from a very early date by Count Rumford and other investigators, and was brought to a high pitch of perfection by Regnault in his extensive calorimetric researches (*Mémoires de l'Institut de Paris*, 1847); but it is only within comparatively recent years that it has really been placed on a satisfactory basis by the accurate definition of the units involved. The theoretical objections to the method, as compared with latent heat calorimetry, are that some heat is necessarily lost by the calorimeter when its temperature is raised above that of the surroundings, and that some heat is used in heating the vessel containing the water. These are small corrections, which can be estimated with considerable accuracy in practice. A more serious difficulty, which has impaired the value of much careful work by this method, is that the quantity of heat required to raise the temperature of a given mass of water 1°C depends on the temperature at which the water is taken, and also on the scale of the thermometer employed. It is for this reason, in many cases, impossible to say, at the present time, what was the precise value of the heat unit, in terms of which many of the older results, such as those of Regnault, were expressed. These difficulties are discussed in the articles CALORIMETRY and THERMOMETRY. The unit generally adopted for scientific purposes is the quantity of heat required to raise 1 gramme of water 1°C , and is called the gramme-calorie. English engineers usually state results in terms of the British Thermal Unit (B.Th.U.), which is the quantity of heat required to raise 1 lb. of water 1°F . (See CALORIE.)

10. **Watt's Indicator Diagram; Work of Expansion.**—The rapid development of the steam-engine (*q.v.*) in England during the latter part of the 18th century had a marked effect on the progress of the science of heat. In the first steam-engines the working cylinder served both as boiler and condenser, a very wasteful method, as most of the heat was transferred directly from the fire to the condensing water without useful effect. The first improvement (about 1700) was to use a separate boiler, but the greater part of the steam supplied was still wasted in reheating the cylinder, which had been cooled by the injection of cold water to condense the steam after the previous stroke. In 1769 James Watt showed how to avoid this waste by using a separate condenser and keeping the cylinder as hot as possible. In his earlier engines the steam at full boiler pressure was allowed to raise the piston through nearly the whole of its stroke. Connection with the boiler was then cut off, and the steam at full pressure was discharged into the condenser. Here again there was unnecessary waste, as the steam was still capable of doing useful work. He subsequently introduced "expansive working," which effected still further economy. The connection with the boiler was cut off when a fraction only, say $\frac{1}{4}$, of the stroke had been completed, the remainder of the stroke being effected by the expansion of the steam already in the cylinder with continually diminishing pressure. By the end of the stroke, when connection was made to the condenser, the pressure was so reduced that there was comparatively little waste from this cause. Watt also devised an instrument called an *indicator* (see STEAM ENGINE), in which a pencil, moved up and down vertically by the steam pressure, recorded the pressure in the cylinder at every point of the stroke on a sheet of paper moving horizontally in time with the stroke of the piston. The diagram thus obtained made it possible to study what was happening inside the cylinder, and to deduce the work done by the steam in each

stroke. The method of the indicator diagram has since proved of great utility in physics in studying the properties of gases and vapours.

Fig. 4 represents an imaginary indicator diagram for a steam-engine, taken from one of Watt's patents. Steam is admitted to the cylinder when the piston is at the beginning of its stroke at S, ST represents the length of the stroke or the limit of horizontal movement of the paper on which the diagram is drawn. The indicating pencil rises to the point A, representing the absolute pressure of 60lb. per sq.in. As the piston moves outwards the pencil traces the horizontal line AB, the pressure remaining constant till the point B is reached, at which connection to the boiler is cut off. After cut-off at B the steam expands under diminishing pressure, and the pencil falls gradually from B to C, following the steam pressure until the exhaust valve opens at the end of the stroke. The pressure then falls rapidly to that of the condenser, which for an ideal case may be taken as zero, following Watt. The work done during expansion is found by dividing up, as shown, into a number of small rectangles. The whole work done in the forward stroke is represented by the area ABCTSA, or by the average value of the pressure \bar{p} over the whole stroke multiplied by the stroke l . This area must be multiplied by the area of the piston a in square inches to get the work done per stroke in foot-pounds.

FIG. 4.—WATT'S INDICATOR DIAGRAM; PATENT OF 1782

11. Thermal Efficiency.—The thermal efficiency of an engine is the ratio of the work done by the engine to the heat supplied to it. According to Watt's observations, confirmed later by Clément and Desormes, the total heat required to produce 1lb. of saturated steam at any temperature from water at 0°C was approximately 650 times the quantity of heat required to raise 1lb. of water 1°C . Since 1lb. of steam represented on this assumption a certain quantity of heat, the efficiency could be measured naturally in foot-pounds of work obtainable per lb. of steam, or conversely in the pounds of steam which are consumed per horsepower-hour.

In his patent of 1782 Watt gives the following example of the improvement in thermal efficiency obtained by expansive working. Taking the diagram already given, if the quantity of steam represented by AB, or 300 cu.in. at 60lb. pressure, were employed without expansion, the work realized, represented by the area ABSF, would be $6,000/4 = 1,500$ foot-pounds. With expansion to 4 times its original volume, as shown in the diagram by the whole area ABCTSA, the mean pressure (as calculated by Watt, assuming Boyle's law) would be 0.58 of the original pressure, and the work done would be $6,000 \times 0.58 = 3,480$ foot-pounds for the same quantity of steam, or the thermal efficiency would be 2.32 times greater. The advantage actually obtained would not be so great as this, on account of losses by condensation, back-pressure, etc., which are neglected in Watt's calculation, but the margin would still be very considerable. Three hundred cu.in. of steam at 60lb. pressure would represent about 0.245 of 1lb. of steam, or 28.7 B.Th.U., so that, neglecting all losses, the possible thermal efficiency attainable with steam at this pressure and four expansions ($\frac{1}{4}$ cut-off) would be $3480/28.7$, or 121 foot-pounds per B.Th.U.

About 1820, it was usual to include the efficiency of the boiler with that of the engine, and to reckon the efficiency or "duty" in foot-pounds per bushel or cwt. of coal. The best Cornish pumping-engines of that date achieved about 70 million foot-pounds per cwt., or consumed about 3.2lb. per horsepower-hour, which is roughly equivalent to 43 foot-pounds per B.Th.U. The efficiency gradually increased as higher pressures were used, with more complete expansion, but the conditions upon which the efficiency depended were not fully worked out till a much later date. Much additional knowledge with regard to the nature of heat, and the properties of gases and vapours, was required before the problem could be attacked theoretically.

THE NATURE OF HEAT

12. In the early days of the science it was natural to ascribe the manifestations of heat to the action of a subtle imponderable fluid called "caloric," with the power of penetrating, expanding and dissolving bodies, or dissipating them in vapour. The fluid was imponderable, because the most careful experiments failed to show that heat produced any increase in weight. The opposite property of levitation was often ascribed to heat, but it was shown by more cautious investigators that the apparent loss of weight due to heating was to be attributed to evaporation or to upward air currents. The fundamental idea of an imaginary fluid to represent heat was useful as helping the mind to a conception of something remaining invariable in quantity through many transformations, but in some respects the analogy was misleading, and tended greatly to retard the progress of science. The caloric theory was very simple in its application to the majority of calorimetric experiments, and gave a fair account of the elementary phenomena of change of state, but it encountered serious difficulties in explaining the production of heat by friction, or the changes of temperature accompanying the compression or expansion of a gas.

The explanation which the calorists offered of the production of heat by friction or compression was that some of the latent caloric was squeezed or ground out of the bodies concerned and became "sensible." In the case of heat developed by friction, they supposed that the abraded portions of the material were capable of holding a smaller quantity of heat, or had less "capacity for heat," than the original material. From a logical point of view, this was a perfectly tenable hypothesis, and one difficult to refute. It was easy to account in this way for the heat produced in boring cannon and similar operations, where the amount of abraded material was large. To refute this explanation, Rumford (*Phil. Trans.*, 1798) made his celebrated experiments with a blunt borer in one of which he succeeded in boiling by friction 26.5lb. of cold water in $2\frac{1}{2}$ hours, with the production of only 4,145 grains of metallic powder. He then showed by experiment that the metallic powder required the same amount of heat to raise its temperature 1° , as an equal weight of the original metal, or that its "capacity for heat" (in this sense) was unaltered by reducing it to powder; and he argued that "in any case so small a quantity of powder could not possibly account for all the heat generated, that the supply of heat appeared to be inexhaustible, and that heat could not be a material substance, but must be something of the nature of motion."

Unfortunately Rumford's argument was not quite conclusive. The supporters of the caloric theory appear, whether consciously or unconsciously, to have used the phrase "capacity for heat" in two entirely distinct senses without any clear definition of the difference. The phrase "capacity for heat" might very naturally denote the total quantity of heat contained in a body, which we have no means of measuring, but it was generally used to signify the quantity of heat required to raise the temperature of a body one degree, which is quite a different thing, and has no necessary relation to the total heat. In proving that the powder and the solid metal required the same quantity of heat to raise the temperature of equal masses of either one degree, Rumford did not prove that they contained equal quantities of heat, which was the real point at issue in this instance. The metal tin actually changes into powder below a certain temperature, and in so doing evolves a measurable quantity of heat. A mixture of the gases oxygen and hydrogen, in the proportions in which they combine to form water, evolves when burnt sufficient heat to raise more than 30 times its weight of water from the freezing to the boiling point; and the mixture of gases may, in this sense, be said to contain so much more heat than the water, although its capacity for heat in the ordinary sense is only about half that of the water produced. To complete the refutation of the calorists' explanation of the heat produced by friction, it would have been necessary for Rumford to show that the powder when reconverted into the same state as the solid metal did not absorb a quantity of heat equivalent to that evolved in the grinding; in other words that the heat produced by friction was not simply that due to the change

of state of the metal from solid to powder.

Shortly afterwards, in 1799, Davy (*see* Sir H. Davy's *Collected Works*, 1839) described an experiment in which he melted ice by rubbing two blocks together. This experiment afforded a very direct refutation of the calorists' view, because it was a well-known fact that ice required to have a quantity of heat added to it to convert it into water, so that the water produced by the friction contained more heat than the ice. In stating as the conclusion to be drawn from this experiment that "friction consequently does not diminish the capacity of bodies for heat," Davy apparently uses the phrase capacity for heat in the sense of total heat contained in a body, because in a later section of the same essay he definitely gives the phrase this meaning, and uses the term "capability of temperature" to denote what we now term capacity for heat.

The delay in the overthrow of the caloric theory, and in the acceptance of the view that heat is a mode of motion, was no doubt partly due to some fundamental confusion of ideas in the use of the term "capacity for heat" and similar phrases. A still greater obstacle lay in the comparative vagueness of the motion or vibration theory. Davy speaks of heat as being "repulsive motion," and distinguishes it from light, which is "projective motion"; though heat is certainly not a substance—according to Davy in the essay under discussion—and may not even be treated as an imponderable fluid, light as certainly is a material substance, and is capable of forming chemical compounds with ordinary matter, such as oxygen gas, which is not a simple substance, but a compound, termed phosoxygen, of light and oxygen.

Accepting the conclusions of Davy and Rumford that heat is not a material substance but a mode of motion, there still remains the question, what definite conception is to be attached to a quantity of heat? What do we mean by a quantity of vibratory motion, how is the quantity of motion to be estimated, and why should it remain invariable in many transformations? The idea that heat was a "mode of motion" was applicable as a qualitative explanation of many of the effects of heat, but it lacked the quantitative precision of a scientific statement, and could not be applied to the calculation and prediction of definite results. The state of science at the time of Rumford's and Davy's experiments did not admit of a more exact generalization. The way was paved in the first instance by a more complete study of the laws of gases, to which Laplace, Dalton, Gay-Lussac, Dulong and many others contributed both on the experimental and theoretical side. Although the development proceeded simultaneously along many parallel lines, it is interesting and instructive to take the investigation of the properties of gases, and to endeavour to trace the steps by which the true theory was finally attained.

THERMAL PROPERTIES OF GASES

13. The most characteristic property of a gaseous or elastic fluid, namely, the elasticity, or resistance to compression, was first investigated scientifically by Robert Boyle (1662), who showed that the pressure p of a given mass of gas varied inversely as the volume v , provided that the temperature remained constant. This is generally expressed by the formula $p v = C$, where C is a constant for any given temperature, and v is taken to represent the specific volume, or the volume of unit mass, of the gas at the given pressure and temperature. Boyle was well aware of the effect of heat in expanding a gas, but he was unable to investigate this properly as no thermometric scale had been defined at that date. According to Boyle's law, when a mass of gas is compressed by a small amount at constant temperature, the percentage increase of pressure is equal to the percentage diminution of volume (if the compression is $v/100$, the increase of pressure is very nearly $p/100$). Adopting this law, Newton showed, by a most ingenious piece of reasoning (*Principia*, ii., sect. 8), that the velocity of sound in air should be equal to the velocity acquired by a body falling under gravity through a distance equal to half the height of the atmosphere, considered as being of uniform density equal to that at the surface of the earth. This gave the result 918 ft. per sec. (280 metres per sec.) for the

velocity at the freezing point. Newton was aware that the actual velocity of sound was somewhat greater than this, but supposed that the difference might be due in some way to the size of the air particles, of which no account could be taken in the calculation. The first accurate measurement of the velocity of sound by the French Académie des Sciences in 1738 gave the value 332 metres per sec. as the velocity at 0°C . The true explanation of the discrepancy was not discovered till nearly 100 years later.

The law of expansion of gases with change of temperature was investigated by Dalton and later by Gay-Lussac (1802), who found that the volume of a gas under constant pressure increased by $\frac{1}{273}$ of its volume at 0°C for each 1°C rise in temperature. This value was generally assumed in all calculations for nearly 50 years. More exact researches, especially those of Regnault, at a later date, showed that the law was very nearly correct for all permanent gases, but that the value of the coefficient should be $\frac{1}{273}$. According to this law the volume of a gas at any temperature $t^\circ \text{C}$ should be proportional to $273+t$, i.e., to the temperature reckoned from a zero 273° below that of the Centigrade scale, which was called the absolute zero of the gas thermometer. If $T = 273+t$, denotes the temperature measured from this zero, the law of expansion of a gas may be combined with Boyle's law in the simple formula

$$p v = R T \quad (1)$$

which is generally taken as the expression of the gaseous laws. If equal volumes of different gases are taken at the same temperature and pressure, it follows that the constant R is the same for all gases. If equal masses are taken, the value of the constant R for different gases varies inversely as the molecular weight or as the density relative to hydrogen.

Dalton also investigated the laws of vapours, and of mixtures of gases and vapours. He found that condensible vapours approximately followed Boyle's law when compressed, until the condensation pressure was reached, at which the vapour liquefied without further increase of pressure. He found that when a liquid was introduced into a closed space, and allowed to evaporate until the space was saturated with the vapour and evaporation ceased, the increase of pressure in the space was equal to the condensation pressure of the vapour, and did not depend on the volume of the space or the presence of any other gas or vapour provided that there was no solution or chemical action. He showed that the condensation or saturation-pressure of a vapour depended only on the temperature, and increased by nearly the same fraction of itself per degree rise of temperature, and that the pressures of different vapours were nearly the same at equal distances from their boiling points. The increase of pressure per degree C at the boiling point was about $\frac{1}{273}$ of 760 mm. or 27.2 mm., but increased in geometrical progression with rise of temperature. These results of Dalton's were confirmed, and in part corrected, as regards increase of vapour-pressure, by Gay-Lussac, Dulong, Regnault and other investigators, but were found to be as close an approximation to the truth as could be obtained with such simple expressions. More accurate empirical expressions for the increase of vapour-pressure of a liquid with temperature were soon obtained by Thomas Young, J. P. L. A. Roche and others, but the explanation of the relation was not arrived at until a much later date (*see* VAPORIZATION).

14. **Specific Heats of Gases.**—In order to estimate the quantities of heat concerned in experiments with gases, it was necessary in the first instance to measure their specific heats, which presented formidable difficulties. The earlier attempts by Lavoisier and others, employing the ordinary methods of calorimetry, gave very uncertain and discordant results, which were not regarded with any confidence even by the experimentalists themselves. Gay-Lussac (*Mémoires d'Arcueil*, 1807) devised an ingenious experiment, which, though misinterpreted at the time, is very interesting and instructive. With the object of comparing the specific heats of different gases, he took two equal globes A and B connected by a tube with a stop-cock. The globe B was exhausted, the other A being filled with gas. On opening the tap between the vessels, the gas flowed from A to B and the pressure was rapidly equalized. He observed that the fall of temperature in A was

nearly equal to the rise of temperature in *B*, and that for the same initial pressure the change of temperature was very nearly the same for all the gases he tried, except hydrogen, which showed greater changes of temperature than other gases. He concluded from this experiment that equal volumes of gases had the same capacity for heat, except hydrogen, which he supposed to have a larger capacity, because it showed a greater effect. The method does not in reality afford any direct information with regard to the specific heats, and the conclusion with regard to hydrogen is evidently wrong.

At a later date (*Ann. de Chim.*, 1812) Gay-Lussac adopted A. Crawford's method of mixture, allowing two equal streams of different gases, one heated and the other cooled about 20° C, to mix in a tube containing a thermometer. The resulting temperature was in all cases nearly the mean of the two, from which he concluded that equal volumes of all the gases tried, namely, hydrogen, carbon dioxide, air, oxygen and nitrogen, had the same thermal capacity. This was correct, except as regards carbon dioxide, but did not give any information as to the actual specific heats referred to water or any known substance. About the same time, F. Delaroche and J. E. Bérard (*Ann. de Chim.*, 1813) made direct determinations of the specific heats of air, oxygen, hydrogen, carbon monoxide, carbon dioxide, nitrous oxide and ethylene, by passing a stream of gas heated to nearly 100° C through a spiral tube in a calorimeter containing water. Their work was a great advance on previous attempts, and gave the first trustworthy results. With the exception of hydrogen, which presents peculiar difficulties, they found that equal volumes of the permanent gases, air, oxygen and carbon monoxide, had nearly the same thermal capacity, but that the compound condensible gases, carbon dioxide, nitrous oxide and ethylene, had larger thermal capacities in the order given. They were unable to state whether the specific heats of the gases increased or diminished with temperature, but from experiments on air at pressures of 740mm. and 1,000mm., they found the specific heats to be .269 and .245 respectively, and concluded that the specific heat diminished with increase of pressure. The difference they observed was really due to errors of experiment, but they regarded it as proving beyond doubt the truth of the calorists' contention that the heat disengaged on the compression of a gas was due to the diminution of its thermal capacity.

Dalton and others had endeavoured to measure directly the rise of temperature produced by the compression of a gas. Dalton had observed a rise of 50° F in a gas when suddenly compressed to half its volume, but no thermometers at that time were sufficiently sensitive to indicate more than a fraction of the change of temperature. Laplace was the first to see in this phenomenon the probable explanation of the discrepancy between Newton's calculation of the velocity of sound and the observed value. The increase of pressure due to a sudden compression, in which no heat was allowed to escape, or as we now call it an *adiabatic* compression, would necessarily be greater than the increase of pressure in a slow isothermal compression, on account of the rise of temperature. As the rapid compressions and rarefactions occurring in the propagation of a sound wave were perfectly adiabatic, it was necessary to take account of the rise of temperature due to compression in calculating the velocity. To reconcile the observed and calculated values of the velocity, the increase of pressure in adiabatic compression must be 1.410 times greater than in isothermal compression. This is the ratio of the adiabatic elasticity of air to the isothermal elasticity. It was a long time, however, before Laplace saw his way to any direct experimental verification of the value of this ratio. At a later date (*Ann. de chim.*, 1816) he stated that he had succeeded in proving that the ratio in question must be the same as the ratio of the specific heat of air at constant pressure to the specific heat at constant volume.

15. Experimental Verification of the Ratio of Specific Heats.—This was a most interesting and important theoretical relation to discover, but unfortunately it did not help much in the determination of the ratio required, because it was not practically possible at that time to measure the specific heat of air at constant volume in a closed vessel. Attempts had been made to do

this, but they had signally failed, on account of the small heat capacity of the gas as compared with the containing vessel. Laplace endeavoured to extract some confirmation of his views from the values given by Delaroche and Bérard for the specific heat of air at 1,000 and 740mm. pressure. On the assumption that the quantities of heat contained in a given mass of air increased in direct proportion to its volume when heated at constant pressure, he deduced, by some rather obscure reasoning, that the ratio of the specific heats *S* and *s* should be about 1.5 to 1, which he regarded as a fairly satisfactory agreement with the value $\gamma = 1.41$ deduced from the velocity of sound.

The ratio of the specific heats could not be directly measured, but a few years later, N. Clément-Desormes (*Journ. de Phys.*, 1819) succeeded in making a direct measurement of the ratio of the elasticities in a very simple manner. He took a large globe containing air at atmospheric pressure and temperature, and removed a small quantity of air. He then observed the defect of pressure p_0 when the air had regained its original temperature. By suddenly opening the globe, and immediately closing it, the pressure was restored almost instantaneously to the atmospheric, the rise of pressure p_0 corresponding to the sudden compression produced. The air, having been heated by the compression, was allowed to regain its original temperature, the tap remaining closed, and the final defect of pressure p_1 was noted. The change of pressure for the same compression performed isothermally is then $p_0 - p_1$. The ratio $p_0 / (p_0 - p_1)$ is the ratio of the adiabatic and isothermal elasticities, provided that p_0 is small compared with the whole atmospheric pressure. In this way he found the ratio 1.354, which is not much smaller than the value 1.410 required to reconcile the observed and calculated values of the velocity of sound. Gay-Lussac and J. J. Welter (*Ann. de chim.*, 1822) repeated the experiment with slight improvements, using expansion instead of compression, and found the ratio 1.375. The experiment has often been repeated since that time, and there is no doubt that the value of the ratio deduced from the velocity of sound is correct, the defect of the value obtained by direct experiment being due to the fact that the compression or expansion is not perfectly adiabatic. Gay-Lussac and Welter found the ratio practically constant for a range of pressure 144 to 1,460mm., and for a range of temperature from -20° to +40° C. The velocity of sound at Quito, at a pressure of 544mm. was found to be the same as at Paris at 760mm. at the same temperature. Assuming on this evidence the constancy of the ratio of the specific heats of air, Laplace (*Mécanique céleste*, v.) showed that, if the specific heat at constant pressure was independent of the temperature, the specific heat per unit volume at a pressure p must vary as $p^{1/\gamma}$ according to the caloric theory. The specific heat per unit mass must then vary as $p^{1/\gamma - 1}$ which he found agreed precisely with the experiment of Delaroche and Bérard already cited. This was undoubtedly a strong confirmation of the caloric theory. Poisson by the same assumptions (*Ann. de chim.*, 1823) obtained the same results, and also showed that the relation between the pressure and the volume of a gas in adiabatic compression or expansion must be of the form $p v^\gamma = \text{constant}$.

P. L. Dulong (*Ann. de chim.*, 1829), adopting a method due to E. F. F. Chladni, compared the velocities of sound in different gases by observing the pitch of the note given by the same tube when filled with the gases in question. He thus obtained the values of the ratios of the elasticities or of the specific heats for the gases employed. For oxygen, hydrogen and carbonic oxide, these ratios were the same as for air. But for carbonic acid, nitrous oxide and olefiant gas, the values were much smaller, showing that these gases experienced a smaller change of temperature in compression. On comparing his results with the values of the specific heats for the same gases found by Delaroche and Bérard, Dulong observed that the changes of temperature for the same compression were in the inverse ratio of the specific heats at constant volume, and deduced the important conclusion that "*Equal volumes of all gases under the same conditions evolve on compression the same quantity of heat.*" This is equivalent to the statement that the difference of the specific heats, or the latent heat of expansion R' per 1°, is the same for all gases if equal

volumes are taken. Assuming the ratio $\gamma=1.410$, and taking Delaroché and Bérard's value for the specific heat of air at constant pressure $S=.267$, we have $s=S/1.41=.189$, and the difference of the specific heats per unit mass of air $S-s=R'=.078$. Adopting Regnault's value of the specific heat of air, namely, $S=.238$, we should have $S-s=.069$. This quantity represents the heat absorbed by unit mass of air in expanding at constant temperature T by a fraction $1/T$ of its volume v , or by $\frac{1}{\gamma-1}$ of its volume at 0°C .

If, instead of taking unit mass, we take a volume $v_0=22.30$ litres at 0°C and 760mm , being the volume of the molecular weight of the gas in grammes, the quantity of heat evolved by a compression equal to v/T will be approximately 2 calories, and is the same for all gases. The work done in this compression is $p\Delta v=RT$, and is also the same for all gases, namely, 8.3 joules. Dulong's experimental result, therefore, shows that the heat evolved in the compression of a gas is proportional to the work done. This result had previously been deduced theoretically by Carnot (1824). At a later date it was assumed by Mayer, Clausius and others, on the evidence of these experiments, that the heat evolved was not merely proportional to the work done, but was equivalent to it. The further experimental evidence required to justify this assumption was first supplied by Joule.

CARNOT: ON THE MOTIVE POWER OF HEAT

16. A practical and theoretical question of the greatest importance was first answered by Sadi Carnot about this time in his *Réflexions sur la puissance motrice du feu* (1824). How much motive power (defined by Carnot as weight lifted through a certain height) can be obtained from heat alone by means of an engine repeating a regular succession or "cycle" of operations continuously? Is the efficiency limited, and, if so, how is it limited? Are other agents preferable to steam for developing motive power from heat? In discussing this problem, we cannot do better than follow Carnot's reasoning which, in its main features, could hardly be improved at the present day. Carnot points out that in order to obtain an answer to this question, it is necessary to consider the essential conditions of the process, apart from the mechanism of the engine and the working substance or agent employed. Work cannot be said to be produced from heat alone unless nothing but heat is supplied, and the working substance and all parts of the engine are at the end of the process in precisely the same state as at the beginning.

For instance a mass of compressed air, if allowed to expand in a cylinder at constant temperature, will do work, and will at the same time absorb a quantity of heat which, as we now know, is the thermal equivalent of the work done. But this work cannot be said to have been produced solely from the heat absorbed in the process, because the air at the end of the process is in a changed condition, and could not be restored to its original state at the same temperature without having work done upon it precisely equal to that obtained by its expansion. The process could not be repeated indefinitely without a continual supply of compressed air. The source of the work in this case is work previously done in compressing the air, and no part of the work is really generated at the expense of heat alone, unless the compression is effected at a lower temperature than the expansion.

Carnot's Axiom. Carnot here, and throughout his reasoning, makes a fundamental assumption, which he states as follows: "When a body has undergone any changes and after a certain number of transformations is brought back identically to its original state, considered relatively to density, temperature and mode of aggregation, it must contain the same quantity of heat as it contained originally." Clausius (*Pogg. Ann.* 79, p. 369) and others have misinterpreted this assumption, and have taken it to mean that the quantity of heat required to produce any given change of state is independent of the manner in which the change is effected, which Carnot does not here assume.

Heat, according to Carnot, in the type of engine we are considering, can evidently be a cause of motive power only by virtue of changes of volume or form produced by alternate heating and cooling. This involves the existence of hot and cold bodies to

act as boiler and condenser, or source and sink of heat, respectively. Wherever there exists a difference of temperature, it is possible to have the production of motive power from heat; and conversely, production of motive power, from heat alone, is impossible without difference of temperature. In other words the production of motive power from heat is not merely a question of the consumption of heat, but always requires transference of heat from hot to cold. What then are the conditions which enable the difference of temperature to be most advantageously employed in the production of motive power, and how much motive power can be obtained with a given difference of temperature from a given quantity of heat?

Carnot's Rule for Maximum Effect.—In order to realize the maximum effect, it is necessary that, in the process employed, there should not be any direct interchange of heat between bodies at different temperatures. Direct transference of heat by conduction or radiation between bodies at different temperatures is equivalent to wasting a difference of temperature which might have been utilized to produce motive power. The working substance must throughout every stage of the process be in equilibrium with itself (*i.e.*, at uniform temperature and pressure) and also with external bodies, such as the boiler and condenser, at such times as it is put in communication with them. In the actual engine there is always some interchange of heat between the steam and the cylinder, and some loss of heat to external bodies. There may also be some difference of temperature between the boiler steam and the cylinder on admission, or between the waste steam and the condenser at release. These differences represent losses of efficiency which may be reduced indefinitely, at least in imagination, by suitable means, and designers had even at that date been very successful in reducing them. All such losses are supposed to be absent in deducing the ideal limit of efficiency, beyond which it would be impossible to go.

17. *Carnot's Description of His Ideal Cycle.*—Carnot first gives a rough illustration of an incomplete cycle, using steam much in the same way as it is employed in an ordinary steam-engine. After expansion down to condenser pressure the steam is completely condensed to water, and is then returned as cold water to the hot boiler. He points out that the last step does not conform exactly to the condition he laid down, because although the

water is restored to its initial state, there is direct passage of heat from a hot body to a cold body in the last process. He points out that this difficulty might be overcome by supposing the difference of temperature small, and by employing a series of engines, each working through a small range, to cover a finite interval of temperature. Having established the general notions of a perfect cycle, he proceeds to give a more exact illustration, employing a gas as the working substance. He takes as the basis of his demonstration the well-established experimental fact that a gas is heated by rapid compression and cooled by rapid expansion, and that if compressed or expanded slowly in contact with conducting bodies, the gas will give out heat in compression or absorb heat in expansion while its temperature remains constant. He then goes on to say:—

FIG. 5.—CARNOT'S CYLINDER

"This preliminary notion being settled, let us imagine an elastic fluid, atmospheric air for example, enclosed in a cylinder $abcd$ (fig. 5) fitted with a movable diaphragm or piston cd . Let there also be two bodies A, B, each maintained at a constant temperature, that of A being more elevated than that of B. Let us now suppose the following series of operations to be performed:

"1. Contact of the body A with the air contained in the space $abcd$, or with the bottom of the cylinder, which we will suppose to transmit heat easily. The air is now at the temperature of the body A, and cd is the actual position of the piston.

"2. The piston is gradually raised, and takes the position *ef*. The air remains in contact with the body A, and is thereby maintained at a constant temperature during the expansion. The body A furnishes the heat necessary to maintain the constancy of temperature.

"3. The body A is removed, and the air no longer being in contact with any body capable of giving it heat, the piston continues nevertheless to rise, and passes from the position *ef* to *gh*. The air expands without receiving heat and its temperature falls. Let us imagine that it falls until it is just equal to that of the body B. At this moment the piston is stopped and occupies the position *gh*.

"4. The air is placed in contact with the body B; it is compressed by the return of the piston, which is brought from the position *gh* to the position *cd*. The air remains meanwhile at a constant temperature, because of its contact with the body B to which it gives up its heat.

"5. The body B is removed, and the compression of the air is continued. The air being now isolated, rises in temperature. The compression is continued until the air has acquired the temperature of the body A. The piston passes meanwhile from the position *cd* to the position *ik*.

"6. The air is replaced in contact with the body A, and the piston returns from the position *ik* to the position *ef*, the temperature remaining invariable.

"7. The period described under (3) is repeated, then successively the periods (4), (5), (6); (3), (4), (5), (6); (3), (4), (5), (6); and so on.

"During these operations the air enclosed in the cylinder exerts an effort more or less great on the piston. The pressure of the air varies both on account of changes of volume and on account of changes of temperature; but it should be observed that for equal volumes, that is to say, for like positions of the piston, the temperature is higher during the dilatation than during the compression. Since the pressure is greater during the expansion, the quantity of motive power produced by the dilatation is greater than that consumed by the compression. We shall thus obtain a balance of motive power, which may be employed for any purpose. The air has served as working substance in a heat-engine; it has also been employed in the most advantageous manner possible, since no useless re-establishment of the equilibrium of heat has been allowed to occur.

"All the operations above described may be executed in the reverse order and direction. Let us imagine that after the sixth period, that is to say, when the piston has reached the position *ef*, we make it return to the position *ik*, and that at the same time we keep the air in contact with the hot body A; the heat furnished by this body during the sixth period will return to its source, that is, to the body A, and everything will be as it was at the end of the fifth period. If now we remove the body A, and if we make the piston move from *ik* to *cd*, the temperature of the air will decrease by just as many degrees as it increased during the fifth period, and will become that of the body B. We can evidently continue in this way a series of operations the exact reverse of those which were previously described; it suffices to place oneself in the same circumstances and to execute for each period a movement of expansion in place of a movement of compression, and vice versa.

"The result of the first series of operations was the production of a certain quantity of motive power, and the transport of heat from the body A to the body B; the result of the reverse operations is the consumption of the motive power produced in the first case, and the return of heat from the body B to the body A, in such sort that these two series of operations annul and neutralize each other.

"The impossibility of producing by the agency of heat alone a quantity of motive power greater than that which we have obtained in our first series of operations is now easy to prove. It is demonstrated by reasoning exactly similar to that which we have already given. The reasoning will have in this case a greater degree of exactitude; the air of which we made use to develop the motive power is brought back at the end of each cycle of opera-

tions precisely to its initial state, whereas this was not quite exactly the case for the vapour of water, as we have already remarked."

18. **Proof of Carnot's Principle.**—Carnot considered the proof too obvious to be worth repeating, but, unfortunately, his previous demonstration, referring to an incomplete cycle, is not so exactly worded that exception cannot be taken to it. We will therefore repeat his proof in a slightly more definite and exact form. Suppose that a reversible engine *R*, working in the cycle above described, takes a quantity of heat *Q* from the source in each cycle, and performs a quantity of useful work *W_r*. If it were possible for any other engine *S*, working with the same two bodies A and B as source and refrigerator, to perform a greater amount of useful work *W_s* per cycle for the same quantity of heat *Q* taken from the source, it would suffice to take a portion *W_r* of this motive power (since *W_s* is by hypothesis greater than *W_r*) to drive the engine *R* backwards, and return a quantity of heat *Q* to the source in each cycle. The process might be repeated indefinitely, and we should obtain at each repetition a balance of useful work *W_s - W_r*, without taking any heat from the source, which is contrary to experience. Whether the quantity of heat taken from the condenser by *R* is equal to that given to the condenser by *S* is immaterial. The hot body A might be a comparatively small boiler, since no heat is taken from it. The cold body B might be the ocean, or the whole earth. We might thus obtain without any consumption of fuel a practically unlimited supply of motive power. Which is absurd.

Carnot's Statement of his Principle.—If the foregoing reasoning be admitted, we must conclude with Carnot that *the motive power obtainable from heat is independent of the agents employed to realize it. The efficiency is fixed solely by the temperatures of the bodies between which, in the last resort, the transfer of heat is effected.* "We must understand here that each of the methods of developing motive power attains the perfection of which it is susceptible. This condition is fulfilled if, according to our rule, there is produced in the body no change of temperature that is not due to change of volume, or in other words, if there is no direct interchange of heat between bodies of sensibly different temperatures."

It is characteristic of a state of frictionless mechanical equilibrium that an indefinitely small difference of pressure suffices to upset the equilibrium and reverse the motion. Similarly in thermal equilibrium between bodies at the same temperature, an indefinitely small difference of temperature suffices to reverse the transfer of heat. Carnot's rule is therefore the criterion of the reversibility of a cycle of operations as regards transfer of heat. It is assumed that the ideal engine is mechanically reversible, that there is not, for instance, any communication between reservoirs of gas or vapour at sensibly different pressures, and that there is no waste of power in friction. If there is equilibrium both mechanical and thermal at every stage of the cycle, the ideal engine will be perfectly reversible. That is to say, all its operations will be exactly reversed as regards transfer of heat and work, when the operations are performed in the reverse order and direction. On this understanding Carnot's principle may be put in a different way, which is often adopted, but is really only the same thing put in different words: *The efficiency of a perfectly reversible engine is the maximum possible, and is a function solely of the limits of temperature between which it works.* This result depends essentially on the existence of a state of thermal equilibrium defined by equality of temperature, and independent, in the majority of cases, of the state of a body in other respects. In order to apply the principle to the calculation and prediction of results, it is sufficient to determine the manner in which the efficiency depends on the temperature for one particular case, since the efficiency must be the same for all reversible engines.

19. Carnot endeavoured to test his results by calculating the amount of work obtainable from an engine on his cycle, using steam as a working substance, and comparing the result with an engine performing a similar cycle, using air as the working substance. He found, using the experimental data available at that time, that the work to be obtained from 1,000 gram-calories of heat was

roughly independent of the working substance, being about 1.13 kilogrammetre per kilo-calorie per 1° fall at 100°C , i.e., when the limits of temperature of the cycle are 101°C and 100°C . He was able to show that the efficiency per degree fall probably diminished with rise of temperature, but the experimental data at that time were too inconsistent to suggest the true relation. He took as the analytical expression of his principle that the efficiency W/Q of a perfect engine taking in heat Q at a temperature $t^\circ\text{C}$, and rejecting heat at the temperature 0°C , must be some function Ft of the temperature t , which would be the same for all substances. The efficiency per degree fall at a temperature t he represented by $F't$, the derived function of Ft . The function $F't$ would be the same for all substances at the same temperature, but would have different values at different temperatures. In terms of this function, which is generally known as Carnot's function, the results obtained in the previous section might be expressed as follows:—

"The increase of volume of a mixture of liquid and vapour per unit-mass vaporized at any temperature, multiplied by the increase of vapour-pressure per degree, is equal to the product of the function Ft by the latent heat of vaporization.

"The difference of the specific heats, or the latent heat of expansion for any substance, multiplied by the function $F't$, is equal to the product of the expansion per degree at constant pressure by the increase of pressure per degree at constant volume."

Since the last two coefficients are the same for all gases if equal volumes are taken, Carnot concluded that: "The difference of the specific heats at constant pressure and volume is the same for equal volumes of all gases at the same temperature and pressure."

Taking the expression $W=RT \log_e r$ for the whole work done by a gas obeying the gaseous laws $p v = RT$ in expanding at a temperature T from a volume 1 (unity) to a volume r , or for a ratio of expansion r , and putting $W'=R \log_e r$ for the work done in a cycle of range 1° , Carnot obtained the expression for the heat absorbed by a gas in isothermal expansion.

$$Q = R \log_e r [F'(t)] \quad (2)$$

He gives several important deductions which follow from this formula, which is the analytical expression of the experimental result already quoted as having been discovered subsequently by Dulong. Employing the above expression for the latent heat of expansion, Carnot deduced a general expression for the specific heat of a gas at constant volume on the basis of the caloric theory. He showed that if the specific heat was independent of the temperature (the hypothesis already adopted by Laplace and Poisson) the function $F'(t)$ must be of the form

$$F'(t) = R/C (t + t_0) \quad (3)$$

where C and t_0 are unknown constants. A similar result follows from his expression for the difference of the specific heats. If this is assumed to be constant and equal to C , the expression for $F'(t)$ becomes R/CT , which is the same as the above if $t_0 = 273$. Assuming the specific heat to be also independent of the volume, he shows that the function $F'(t)$ should be constant. But this assumption is inconsistent with the caloric theory of latent heat of expansion, which requires the specific heat to be a function of the volume. It appears in fact impossible to reconcile Carnot's principle with the caloric theory on any simple assumptions. As Carnot remarks: "The main principles on which the theory of heat rests require most careful examination. Many experimental facts appear almost inexplicable in the present state of this theory."

Carnot's work was subsequently put in a more complete analytical form by B. P. E. Clapeyron (*Journ. de l'éc. polytechn.*, 1832), who also made use of Watt's indicator diagram for the first time in discussing physical problems. Clapeyron gave the general expressions for the latent heat of a vapour, and for the latent heat of isothermal expansion of any substance, in terms of Carnot's function, employing the notation of the calculus. The expressions he gave are the same in form as those in use at the present time. He also gave the general expression for Carnot's function, and endeavoured to find its variation with temperature; but having

no better data, he succeeded no better than Carnot. Unfortunately, in describing Carnot's cycle, he assumed the caloric theory of heat, and made some unnecessary mistakes, which Carnot (who, we now know, was a believer in the mechanical theory) had been very careful to avoid. Clapeyron directs one to compress the gas at the lower temperature in contact with the body B *until the heat disengaged is equal to that which has been absorbed at the higher temperature*. He assumes that the gas at this point contains the same quantity of heat as it contained in its original state at the higher temperature, and that, when the body B is removed, the gas will be restored to its original temperature, when compressed to its initial volume. This mistake is still attributed to Carnot, and regarded as a fatal objection to his reasoning by many writers.

Prof. W. Thomson (Lord Kelvin) stated (*Phil. Mag.*, 1852) that "Carnot's original demonstration utterly fails," and he introduced the "corrections" attributed to James Thomson and Clerk Maxwell respectively. In reality Carnot's original demonstration requires no correction.

MECHANICAL THEORY OF HEAT

20. According to the caloric theory, the heat absorbed in the expansion of a gas became latent, like the latent heat of vaporization of a liquid, but remained in the gas and was again evolved on compressing the gas. This theory gave no explanation of the source of the motive power produced by expansion. The mechanical theory had explained the production of heat by friction as being due to transformation of visible motion into a brisk agitation of the ultimate molecules, but it had not so far given any definite explanation of the converse production of motive power at the expense of heat. The theory could not be regarded as complete until it had been shown that in the production of work from heat, a certain quantity of heat disappeared, and ceased to exist as heat; and that this quantity was the same as that which could be generated by the expenditure of the work produced. The earliest complete statement of the mechanical theory from this point of view is contained in some notes written by Carnot, about 1830, but published by his brother (*Life of Sadi Carnot*, Paris, 1878). Taking the difference of the specific heats to be .078, he estimated the mechanical equivalent at 370 kilogrammetres. But he fully recognized that there were no experimental data at that time available for a quantitative test of the theory, although it appeared to afford a good qualitative explanation of the phenomena. He therefore planned a number of crucial experiments such as the *porous plug* experiment, to test the equivalence of heat and motive power. His early death in 1836 put a stop to these experiments, but many of them have since been independently carried out by other observers.

The most obvious case of the production of work from heat is in the expansion of a gas or vapour, which served in the first instance as a means of calculating the ratio of equivalence, on the assumption that all the heat which disappeared had been transformed into work and had not merely become latent. Marc Séguin, in his *De l'influence des chemins de fer* (1839), made a rough estimate in this manner of the mechanical equivalent of heat, assuming that the loss of heat represented by the fall of temperature of steam on expanding was equivalent to the mechanical effect produced by the expansion. He also remarks (*loc. cit.*) that it was absurd to suppose that "a finite quantity of heat could produce an indefinite quantity of mechanical action, and that it was more natural to assume that a certain quantity of heat disappeared in the very act of producing motive power." J. R. Mayer (*Liebig's Annalen*, 1842) stated the equivalence of heat and work more definitely, deducing it from the old principle, *causa aequat effectum*. Assuming that the sinking of a mercury column by which a gas was compressed was equivalent to the heat set free by the compression, he deduced that the warming of a kilogramme of water 1°C would correspond to the fall of a weight of one kilogramme from a height of about 365 metres. But Mayer did not adduce any fresh experimental evidence, and made no attempt to apply his theory to the fundamental equations of thermodynamics. It has since been urged that the experiment of Gay-

Lussac (1807), on the expansion of gas from one globe to another (see § 14), was sufficient justification for the assumption tacitly involved in Mayer's calculation. But Joule was the first to supply the correct interpretation of this experiment, and to repeat it on an adequate scale with suitable precautions. Joule was also the first to measure directly the amount of heat liberated by the compression of a gas, and to prove that heat was not merely rendered latent, but disappeared altogether as heat, when a gas did work in expansion.

21. Joule's Determinations of the Mechanical Equivalent.

The honour of placing the mechanical theory of heat on a sound *experimental* basis belongs almost exclusively to J. P. Joule, who showed by direct experiment that in all the most important cases in which heat was generated by the expenditure of mechanical work, or mechanical work was produced at the expense of heat, there was a constant ratio of equivalence between the heat generated and the work expended and vice versa. His first experiments were on the relation of the chemical and electric energy expended to the heat produced in metallic conductors and voltaic and electrolytic cells; these experiments were described in a series of papers published in the *Phil. Mag.*, 1840-43. He first proved the relation, known as Joule's law, that the heat produced in a conductor of resistance R by a current C is proportional to $C^2 R$ per second. He went on to show that the total heat produced in any voltaic circuit was proportional to the electromotive force E of the battery and to the number of equivalents electrolysed in it. Faraday had shown that electromotive force depends on chemical affinity. Joule measured the corresponding heats of combustion, and showed that the electromotive force corresponding to a chemical reaction is proportional to the heat of combustion of the electro-chemical equivalent. He also measured the E.M.F. required to decompose water, and showed that when part of the electric energy EC is thus expended in a voltameter, the heat generated is less than the heat of combustion corresponding to EC by a quantity representing the heat of combustion of the decomposed gases.

Joule's papers so far had been concerned with the relations between electrical energy, chemical energy and heat which he showed to be mutually equivalent. The first paper in which he discussed the relation of heat to mechanical power was entitled "On the Calorific Effects of Magneto-Electricity, and on the Mechanical Value of Heat" (*Brit. Assoc.*, 1843; *Phil. Mag.*, 1887). In this paper he showed that the heat produced by currents generated by magneto-electric induction followed the same law as voltaic currents. By a simple and ingenious arrangement he succeeded in measuring the mechanical power expended in producing the currents, and deduced the mechanical equivalent of heat and of electrical energy. The amount of mechanical work required to raise 1 lb. of water $1^\circ F$ (1 B.Th.U.), as found by this method, was 838 foot-pounds. In a note added to the paper he states that he found the value 770 ft.lb. by the more direct method of forcing water through fine tubes. In a paper "On the Changes of Temperature produced by the Rarefaction and Condensation of Air" (*Phil. Mag.*, 1845), he made the first direct measurements of the quantity of heat disengaged by compressing air, and also of the heat absorbed when the air was allowed to expand against atmospheric pressure; as the result he deduced the value 798 ft.lb. for the mechanical equivalent of 1 B.Th.U. He also showed that there was no appreciable absorption of heat when air was allowed to expand in such a manner as not to develop mechanical power, and he pointed out that the mechanical equivalent of heat could not be satisfactorily deduced from the relations of the specific heats, because the knowledge of the specific heats of gases at that time was of so uncertain a character.

He attributed most weight to his later determinations of the mechanical equivalent made by the direct method of friction of liquids. He showed that the results obtained with different liquids, water, mercury and sperm oil, were the same, namely, 782 ft.lb.; and finally repeating the method with water, using all the precautions and improvements which his experience had suggested, he obtained the value 772 ft.lb., which was accepted universally for many years, and has only recently required alteration on

account of the more exact definition of the heat unit, and the standard scale of temperature (see CALORIMETRY). The great value of Joule's work for the general establishment of the principle of the conservation of energy lay in the variety and completeness of the experimental evidence he adduced. It was not sufficient to find the relation between heat and mechanical work or other forms of energy in one particular case. It was necessary to show that the same relation held in all cases which could be examined experimentally, and that the ratio of equivalence of the different forms of energy, measured in different ways, was independent of the manner in which the conversion was effected and of the material or working substance employed.

As the result of Joule's experiments, we are justified in concluding that heat is a form of energy, and that all its transformations are subject to the general principle of the conservation of energy. As applied to heat, the principle is called the first law of thermodynamics, and may be stated as follows: *When heat is transformed into any other kind of energy, or vice versa, the total quantity of energy remains invariable; that is to say, the quantity of heat which disappears is equivalent to the quantity of the other kind of energy produced and vice versa.*

The number of units of mechanical work equivalent to one unit of heat is generally called the mechanical equivalent of heat, or Joule's equivalent, and is denoted by the letter J . Its numerical value depends on the units employed for heat and mechanical energy respectively. The values of the equivalent in terms of the units most commonly employed at the present time are as follows:—

777 foot-pounds (Lat. 45°)	= 1 B.Th.U. (lb. deg. Fahr.)
1,399 foot-pounds (Lat. 45°)	= 1 lb. deg. C (lb.-calorie)
426.3 kilogrammetres	= 1 kilogram-deg. C or kilo-calorie.
426.3 grammes	= 1 gram-deg. C
4,180 joules or watt-seconds	= 1 gramme-calorie.
1,161 watt-hours	= 1 kg. calorie.
1,161 kilowatt-hours	= 1 tonne calorie.

The water for the heat units is supposed to be taken at $20^\circ C$ or $68^\circ F$, and the degree of temperature is supposed to be measured by the hydrogen thermometer. The acceleration of gravity in latitude 45° is taken as 980.6 C.G.S. For details of more recent and accurate methods of determination, the reader should refer to the article CALORIMETRY, where tables of the variation of the specific heat of water with temperature are also given.

The *second law of thermodynamics* is a title often used to denote Carnot's principle or some equivalent mathematical expression. In some cases this title is not conferred on Carnot's principle itself, but on some axiom from which the principle may be indirectly deduced. These axioms, however, cannot as a rule be directly applied, so that it would appear preferable to take Carnot's principle itself as the second law. It may be observed that, as a matter of history, Carnot's principle was established and generally admitted before the principle of the conservation of energy as applied to heat, and that from this point of view the titles, first and second laws, are not particularly appropriate.

22. Combination of Carnot's Principle with the Mechanical Theory.—A very instructive paper, showing the state of the science of heat about this time, is that of C. H. A. Holtzmann, "On the Heat and Elasticity of Gases and Vapours" (Mannheim, 1845; Taylor's *Scientific Memoirs*, iv.) who points out that the theory of Laplace and Poisson does not agree with facts when applied to vapours, and that Clapeyron's formulae, though probably correct, contain an undetermined function (Carnot's F/t , Clapeyron's $1/C$) of the temperature. He determines the value of this function to be J/T by assuming, with Séguin and Mayer, that the work done in the isothermal expansion of a gas is a measure of the heat absorbed. From the then accepted value .078 of the difference of the specific heats of air, he finds the numerical value of J to be 374 kilogrammetres per kilo-calorie. Assuming the heat equivalent of the work to remain in the gas, he obtains expressions similar to Clapeyron's for the total heat and the specific heats. In consequence of this assumption, the formulae he obtained for adiabatic expansion were necessarily wrong, but no data existed at that time for testing them. In applying his

formulae to vapours, he obtained an expression for the saturation-pressure of steam, which agreed with the empirical formula of Roche, and satisfied other experimental data on the supposition that the coefficient of expansion of steam was .00423, and its specific heat 1.69—values which are now known to be impossible, but which appeared at the time to give a very satisfactory explanation of the phenomena.

The essay of Hermann Helmholtz, *On the Conservation of Force* (Berlin, 1847), discussed all the known cases of the transformation of energy, and is justly regarded as one of the chief landmarks in the establishment of the energy-principle. Helmholtz gives an admirable statement of the fundamental principle as applied to heat, but makes no attempt to formulate the correct equations of thermodynamics on the mechanical theory. He points out the fallacy of Holtzmann's (and Mayer's) calculation of the equivalent, but admits that it is supported by Joule's experiments, though he does not seem to appreciate the true value of Joule's work. He considers that Holtzmann's formulae are well supported by experiment, and are much preferable to Clapeyron's, because the value of the undetermined function $F't$ is found. But he fails to notice that Holtzmann's equations are fundamentally inconsistent with the conservation of energy, because the heat equivalent of the external work done is supposed to remain in the gas.

That a quantity of heat equivalent to the work performed actually disappears when a gas does work in expansion, was first shown by Joule in the paper on condensation and rarefaction of air (1845) already referred to. At the conclusion of this paper he felt justified by direct experimental evidence in reasserting definitely the hypothesis of Ségiun (*loc. cit.*) that "the steam while expanding in the cylinder loses heat in quantity exactly proportional to the mechanical force developed, and that on the condensation of the steam the heat thus converted into power is not given back." He did not see his way to reconcile this conclusion with Clapeyron's description of Carnot's cycle. At a later date, in a letter to Prof. W. Thomson (Lord Kelvin) (1848), he pointed out that, since, according to his own experiments, the work done in the expansion of a gas at constant temperature is equivalent to the heat absorbed, by equating Carnot's expressions (given in § 19) for the work done and the heat absorbed, the value of Carnot's function $F't$ must be equal to J/T , in order to reconcile his principle with the mechanical theory.

Prof. W. Thomson gave an account of Carnot's theory (*Trans. Roy. Soc. Edin.*, 1849), in which he recognized the discrepancy between Clapeyron's statement and Joule's experiments, but did not see his way out of the difficulty. He therefore adopted Carnot's principle provisionally, and proceeded to calculate a table of values of Carnot's function $F't$, from the values of the total-heat and vapour-pressure of steam then recently determined by Regnault (*Mémoires de l'Institut de Paris*, 1847). In making the calculation, he assumed that the specific volume v of saturated steam at any temperature T and pressure p is that given by the gaseous laws, $pv=RT$. The results are otherwise correct so far as Regnault's data are accurate, because the values of the efficiency per degree $F't$ are not affected by any assumption with regard to the nature of heat. He obtained the values of the efficiency over a finite range from t to 0° C, by adding up the values of $F't$ for the separate degrees. This latter proceeding is inconsistent with the mechanical theory, but is the correct method on the assumption that the heat given up to the condenser is equal to that taken from the source. The values he obtained for $F't$ agreed very well with those previously given by Carnot and Clapeyron, and showed that this function diminishes with rise of temperature roughly in the inverse ratio of T , as suggested by Joule.

R. J. E. Clausius (*Pogg. Ann.*, 1850) and W. J. M. Rankine (*Trans. Roy. Soc. Edin.*, 1850) were the first to develop the correct equations of thermodynamics on the mechanical theory. When heat was supplied to a body to change its temperature or state, part remained in the body as intrinsic heat energy E , but part was converted into external work of expansion W and ceased to exist as heat. The part remaining in the body was always the same for the same change of state, however performed, as re-

quired by Carnot's fundamental axiom, but the part corresponding to the external work was necessarily different for different values of the work done. Thus in any cycle in which the body was exactly restored to its initial state, the heat remaining in the body would always be the same, or as Carnot puts it, the quantities of heat absorbed and given out in its diverse transformations are exactly "compensated," so far as the body is concerned. But the quantities of heat absorbed and given out are not necessarily equal. On the contrary, they differ by the equivalent of the external work done in the cycle. Applying this principle to the case of steam, Clausius deduced a fact previously unknown, that the specific heat of steam maintained in a state of saturation is negative, which was also deduced by Rankine (*loc. cit.*) about the same time. In applying the principle to gases Clausius assumes (with Mayer and Holtzmann) that the heat absorbed by a gas in isothermal expansion is equivalent to the work done, but he does not appear to be acquainted with Joule's experiment, and the reasons he adduces in support of this assumption are not conclusive. This being admitted, he deduces from the energy principle alone the propositions already given by Carnot with reference to gases, and shows in addition that the specific heat of a perfect gas must be independent of the density.

In the second part of his paper Clausius introduces Carnot's principle, which he quotes as follows: "The performance of work is equivalent to a transference of heat from a hot to a cold body without the quantity of heat being thereby diminished." This is quite different from Carnot's way of stating his principle (*see* § 18), and has the effect of exaggerating the importance of Clapeyron's unnecessary assumption. By equating the expressions given by Carnot for the work done and the heat absorbed in the expansion of a gas, he deduces (following Holtzmann) the value J/T for Carnot's function $F't$ (which Clapeyron denotes by $1/C$). He shows that this assumption gives values of Carnot's function which agree fairly well with those calculated by Clapeyron and Thomson, and that it leads to values of the mechanical equivalent not differing greatly from those of Joule. Substituting the value J/T for C in the analytical expressions given by Clapeyron for the latent heat of expansion and vaporization, these relations are immediately reduced to their modern form (*see* THERMODYNAMICS). Being unacquainted with Carnot's original work, but recognizing the invalidity of Clapeyron's description of Carnot's cycle, Clausius substituted a proof consistent with the mechanical theory, which he based on the axiom that "heat cannot of itself pass from cold to hot." The proof on this basis involves the application of the energy principle, which does not appear to be necessary, and the axiom to which final appeal is made does not appear more convincing than Carnot's. Strange to say, Clausius did not in this paper give the expression for the efficiency in a Carnot cycle of finite range (Carnot's $F't$) which follows immediately from the value J/T assumed for the efficiency $F't$ of a cycle of infinitesimal range at the temperature t° C or T° A.

Rankine did not make the same assumption as Clausius explicitly, but applied the mechanical theory of heat to the development of his hypothesis of molecular vortices, and deduced from it a number of results similar to those obtained by Clausius. Unfortunately the paper (*loc. cit.*) was not published till some time later, but in a summary given in the *Phil. Mag.* (1851) the principal results were detailed. Assuming the value of Joule's equivalent, Rankine deduced the value 0.2404 for the specific heat of air at constant pressure, in place of 0.267 as found by Delaroche and Bérard. The subsequent verification of this value by Regnault (*Comptes rendus*, 1853) afforded strong confirmation of the accuracy of Joule's work. In a note appended to the abstract in the *Phil. Mag.* Rankine states that he has succeeded in proving that the maximum efficiency of an engine working in a Carnot cycle of finite range t_1 to t_0 is of the form $(t_1-t_0)/(t_1-k)$, where k is a constant, the same for all substances. This is correct if t represents temperature Centigrade, and $k=-273$.

Prof. W. Thomson (Lord Kelvin) in a paper "On the Dynamical Theory of Heat" (*Trans. Roy. Soc. Edin.*, 1851, first published in the *Phil. Mag.*, 1852) gave a very clear statement of the position of the theory at that time. He showed that the value

$F't = J/T$, assumed for Carnot's function by Clausius without any experimental justification, rested solely on the evidence of Joule's experiment, and might possibly not be true at all temperatures. Assuming the value J/T with this reservation, he gave as the expression for the efficiency over a finite range t_1° to t_0° C, or T_1° to T_0° A, the result,

$$W/Q = (t_1 - t_0)/(t_1 + 273) = (T_1 - T_0)/T_1 \quad (4)$$

which, he observed, agrees in form with that found by Rankine.

23. The Absolute Scale of Temperature.—Since Carnot's function is the same for all substances at the same temperature, and is a function of the temperature only, it supplies a means of measuring temperature independently of the properties of any particular substance. This proposal was first made by Lord Kelvin (*Phil. Mag.*, 1848), who suggested that the degree of temperature should be chosen so that the efficiency of a perfect engine at any point of the scale should be the same, or that Carnot's function $F't$ should be constant. This would give the simplest expression for the efficiency of the caloric theory, but the scale so obtained, when the values of Carnot's function were calculated from Regnault's observations on steam, was found to differ considerably from the scale of the mercury or air-thermometer. At a later date, when it became clear that the value of Carnot's function was very nearly proportional to the reciprocal of the temperature T measured from the absolute zero of the gas thermometer, he proposed a simpler method (*Phil. Trans.*, 1854), namely, to define absolute temperature T as proportional to the reciprocal of Carnot's function. On this definition of absolute temperature, the expression $(T - T_0)/T$ for the efficiency of a Carnot cycle with limits T and T_0 would be exact, and it became a most important problem to determine how far the temperature by gas thermometer differed from the absolute temperature. With this object he devised a very delicate method, known as the *porous plug experiment* (see THERMODYNAMICS), of testing the deviation of the gas thermometer from the absolute scale. The experiments were carried out in conjunction with Joule, and finally resulted in showing ("On the Thermal Effects of Fluids in Motion," *Phil. Trans.*, 1862) that the deviations of the air thermometer from the absolute scale as above defined are almost negligible, and that in the case of the gas hydrogen the deviations are so small that a thermometer containing this gas may be taken for all practical purposes as agreeing exactly with the absolute scale at all ordinary temperatures. For this reason the hydrogen thermometer has since been generally adopted as the standard.

AVAILABILITY OF HEAT OF COMBUSTION

24. Taking the value of 1.13 kilogrammetres per kilo-calorie for 1° C fall of temperature at 100° C, Carnot attempted to estimate the possible performance of a steam-engine receiving heat at 160° C and rejecting it at 40° C. Assuming the performance to be simply proportional to the temperature fall, the work done for 120° fall would be 134 kilogrammetres per kilo-calorie. To make an accurate calculation required a knowledge of the variation of the function $F't$ with temperature. Taking the accurate formula of § 22, the work obtainable is 118 kilogrammetres per kilo-calorie, which is 28% of 426, the mechanical equivalent of the kilo-calorie in kilogrammetres. Carnot pointed out that the fall of 120° C utilized in the steam-engine was only a small fraction of the whole temperature fall obtainable by combustion, and made an estimate of the total power available if the whole fall could be utilized, allowing for the probable diminution of the function $F't$ with rise of temperature. His estimate was 3.9 million kilogrammetres per kilogramme of coal. This was certainly an over-estimate, but was surprisingly close, considering the scanty data at his disposal.

In reality the fraction of the heat of combustion available, even in an ideal engine and apart from practical limitations, is much less than might be inferred from the efficiency formula of the Carnot cycle, by taking the temperature obtainable by the combustion of the fuel as the upper limit of temperature in the formula. For carbon burnt *in air* at constant pressure without any loss of heat, the products of combustion might be raised $2,300^\circ$ C in temperature, assuming that the specific heats of the products were constant and that there was no dissociation. If all

the heat could be supplied to the working fluid at this temperature, that of the condenser being 40° C, the possible efficiency by the formula of § 22 would be 89%. But it is obvious that this could not be done even under the most ideal conditions. The heat given up by the products of combustion in cooling to atmospheric temperature could not be received by the boiler at $2,300^\circ$ but at intermediate temperatures from $2,300^\circ$, to 40° , which would reduce the mean effective temperature of heat reception from $2,300^\circ$ to $1,640^\circ$, and the ideal efficiency from 89 to 62%. This, however, assumes a perfect regenerative boiler in which the working fluid leaves the boiler at a temperature of $2,300^\circ$, although the mean temperature of heat reception cannot exceed $1,640^\circ$. Carnot foresaw that there would be further limitations in the case of the steam-engine owing to the properties of the working fluid.

The greater part of the heat required for generating steam in a boiler is the latent heat of vaporization, which is necessarily received by the steam at the saturation temperature corresponding to the pressure at which the boiler is designed to work. Thus at a pressure of 680 lb. per sq. in., which is about the highest at present utilized on a large scale, the latent heat of vaporization, amounting to about 400 calories, would be received at a temperature of only 260° C (500° F) permitting an ideal efficiency of 41% for the conversion of this part of the heat. But if the feed-water from the condenser at 40° is pumped directly into the boiler, to heat it to 260° , the heat required, amounting to about 230 cal., would be received by the feed-water at intermediate temperatures, and could not be so efficiently utilized. Rankine (*Phil. Trans.* 1854) was the first to show how the work obtainable from this part of the heat could be calculated. His formula gives an ideal efficiency of conversion of 25% for heat supplied in equal instalments between 40° and 260° . This would reduce the efficiency of an engine using the Rankine cycle with saturated steam at 680 lb. pressure to 35% as compared with 41% for the Carnot cycle, in terms of the heat actually received by the steam. If the temperature of the boiler were further raised to 360° C, corresponding to a pressure of 2,700 lb. (nearly four times as great as at 260°), the ideal efficiency of the Carnot cycle would be just over 50%, or half the latent heat could be utilized by a perfect engine. But the latent heat at 360° is only 177 calories, and is less than half the heat required for feed-heating, which amounts to 400 calories, so that the corresponding efficiency of the Rankine cycle is only 38%, which is very near the limit theoretically attainable in this cycle with saturated steam.

25. Advantages of Internal Combustion.—As Carnot pointed out, the chief advantage of using atmospheric air as a working fluid in a heat-engine lies in the possibility of imparting heat to it directly by internal combustion. Even with internal combustion, however, the full range of temperature is not available, because the heat cannot in practice be communicated to the working fluid at constant temperature, owing to the large range of expansion at constant temperature required for the absorption of a sufficient quantity of heat. Air-engines of this type, such as Stirling's or Ericsson's, taking in heat at constant temperature, though theoretically the most perfect, are bulky and mechanically inefficient.

In practical engines the heat is generated by the combustion of an explosive mixture at constant volume or at constant pressure. The heat is not all communicated at the highest temperature, but over a range of temperature from that of the mixture at the beginning of combustion to the maximum temperature. The earliest instance of this type of engine is the lycopodium engine of M. M. Niepce, discussed by Carnot, in which a combustible mixture of air and lycopodium powder at atmospheric pressure was ignited in a cylinder, and did work on a piston. The early gas-engines of E. Lenoir (1860) and N. Otto and E. Langen (1866), operated in a similar manner with illuminating gas in place of lycopodium. Combustion in this case is effected practically at constant volume, and the maximum efficiency theoretically obtainable is $1 - \log_e r / (r - 1)$, where r is the ratio of the maximum temperature T to the initial temperature T_0 . In order to obtain this efficiency it would be necessary to follow Carnot's rule, and expand the gas after ignition without loss or gain of heat from T

down to T_0 , and then to compress it at T_0 to its initial volume. If the rise of temperature in combustion were $2,300^\circ\text{C}$, and the initial temperature were 0°C or 273°A , the theoretical efficiency would be 73.3%, which is much greater than that obtainable with a boiler. But in order to reach this value, it would be necessary to expand the mixture to about 270 times its initial volume, which is obviously impracticable. Owing to incomplete expansion and rapid cooling of the heated gases by the large surface exposed, the actual efficiency of the Lenoir engine was less than 5%, and of the Otto and Langen, with more rapid expansion, about 10%.

Carnot foresaw that in order to render an engine of this type practically efficient, it would be necessary to compress the mixture before ignition. Compression is beneficial in three ways: (1) it permits a greater range of expansion after ignition; (2) it raises the mean effective pressure, and thus improves the mechanical efficiency and the power in proportion to size and weight; (3) it reduces the loss of heat during ignition by reducing the surface exposed to the hot gases. In the modern gas or petrol motor, compression is employed as in Carnot's cycle, but the efficiency attainable is limited not so much by considerations of temperature as by limitations of volume. It is impracticable before combustion at constant volume to compress a rich mixture to much less than one-fifth of its initial volume, and, for mechanical simplicity, the range of expansion is made equal to that of compression. The cycle employed was patented in 1862 by Beau de Rochas, but was first successfully carried out by Otto (1876). It differs from the Carnot cycle in employing reception and rejection of heat at constant volume instead of at constant temperature. This cycle is not so efficient as the Carnot cycle for given limits of temperature, but, for the given limits of volume imposed, it gives a much higher efficiency than the Carnot cycle. The efficiency depends only on the range of temperature in expansion and compression, and is given by the formula $(T_1 - T_2)/T_1$, where T_1 is the maximum temperature, and T_2 the temperature at the end of expansion. The formula is the same as that for the Carnot cycle with the same range of temperature in expansion. The ratio T_1/T_2 is $r^{\gamma-1}$ where r is the given ratio of expansion or compression, and γ is the ratio of the specific heats of the working fluid. Assuming the working fluid to be a perfect gas with the same properties as air, we should have $\gamma = 1.41$. Taking $r = 5$, the formula gives 48% for the maximum possible efficiency. The actual products of combustion vary with the nature of the fuel employed, and have different properties from air, but the efficiency is found to vary with compression in the same manner as for air. For this reason a committee of the Institution of Civil Engineers in 1905 recommended the adoption of the air-standard for estimating the effects of varying the compression ratio, and defined the relative efficiency of an internal combustion engine as the ratio of its observed efficiency to that of a perfect air-engine with the same compression.

26. Effect of Dissociation, and Increase of Specific Heat.

—One of the most important effects of heat is the decomposition or dissociation of compound molecules. Just as the molecules of a vapour combine with evolution of heat to form the more complicated molecules of the liquid, and as the liquid molecules require the addition of heat to effect their separation into molecules of vapour; so in the case of molecules of different kinds which combine with evolution of heat, the reversal of the process can be effected either by the agency of heat, or indirectly by supplying the requisite amount of energy by electrical or other methods. Just as the latent heat of vaporization diminishes with rise of temperature, and the pressure of the dissociated vapour molecules increases, so in the case of compound molecules in general the heat of combination diminishes with rise of temperature, and the pressure of the products of dissociation increases. There is evidence that the compound carbon dioxide, CO_2 , is partly dissociated into carbon monoxide and oxygen at high temperatures, and that the proportion dissociated increases with rise of temperature. There is a very close analogy between these phenomena and the vaporization of a liquid. The laws which govern dissociation are the same fundamental laws of thermodynamics, but the relations involved are necessarily more complex

on account of the presence of different kinds of molecules, and present special difficulties for accurate investigation in the case where dissociation does not begin to be appreciable until a high temperature is reached.

It is easy, however, to see that the general effect of dissociation must be to diminish the available temperature of combustion, and all experiments go to show that in ordinary combustible mixtures the rise of temperature actually attained is much less than that calculated as in § 24, on the assumption that the whole heat of combustion is developed and communicated to products of constant specific heat. The defect of temperature observed can be represented by supposing that the specific heat of the products of combustion increases with rise of temperature. This is the case for CO_2 even at ordinary temperatures, according to Regnault, and probably also for air and steam at higher temperatures. Increase of specific heat is a necessary accompaniment of dissociation, and from some points of view may be regarded as merely another way of stating the facts. It is the most convenient method to adopt in the case of products of combustion consisting of a mixture of CO_2 and steam with a large excess of inert gases, because the relations of equilibrium of dissociated molecules of so many different kinds would be too complex to permit of any other method of expression.

It appears from the researches of Dugald Clerk, H. le Chatelier and others that the apparent specific heat of the products of combustion in a gas-engine may be taken as approximately .34 to .33 in place of .24 at working temperatures between $1,000^\circ\text{C}$ and $1,700^\circ\text{C}$, and that the ratio of the specific heats is about 1.29 in place of 1.41. This limits the availability of the heat of combustion by reducing the rise of temperature actually obtainable in combustion at constant volume by 30 or 40%, and also by reducing the range of temperature T_1/T_2 for a given ratio of expansion r from $r^{.41}$ to $r^{.29}$. The formula given in § 23 is no longer quite exact, because the ratio of the specific heats of the mixture during compression is not the same as that of the products of combustion during expansion. But since the work done depends principally on the expansion curve, the ratio of the range of temperature in expansion $(T_1 - T_2)$ to the maximum temperature T_1 will still give a very good approximation to the possible efficiency. Taking $r = 5$, as before, for the compression ratio, the possible efficiency is reduced from 48% to 38%, if $\gamma = 1.29$ instead of 1.41. A large gas-engine of the present time with $r = 5$ may actually realize as much as 34% indicated efficiency, which is 90% of the maximum possible, showing how perfectly all avoidable heat losses have been minimized.

It is often urged that the gas-engine is relatively less efficient than the steam-engine, because, although it has a much higher absolute efficiency, it does not utilize so large a fraction of its temperature range, reckoning that of the steam-engine from the temperature of the boiler to that of the condenser, and that of the gas-engine from the maximum temperature of combustion to that of the air. This is not quite fair, and has given rise to the mistaken notion that "there is an immense margin for improvement in the gas-engine," which is not the case if the practical limitations of volume are rightly considered. If expansion could be carried out in accordance with Carnot's principle of maximum efficiency, down to the lower limit of temperature T_0 , with rejection of heat at T_0 during compression to the original volume v_0 , it would no doubt be possible to obtain an ideal efficiency of nearly 80%. But this would be quite impracticable, as it would require expansion to about 100 times v_0 , or 500 times the compression volume. Some advantage no doubt might be obtained by carrying the expansion beyond the original volume. This has been done, but is not found to be worth the extra complication. A more practical method, which has been applied by Diesel for liquid fuel, is to introduce the fuel at the end of compression, and adjust the supply in such a manner as to give combustion at nearly constant pressure. This makes it possible to employ higher compression, with a corresponding increase in the ratio of expansion and the theoretical efficiency. With a compression ratio of 14, an indicated efficiency of 40% has been obtained in this way, but owing to additional complications the

brake efficiency was only 31%, which is hardly any improvement on the brake efficiency of 30% obtained with the ordinary type of gas-engine.

Although Carnot's principle makes it possible to calculate in every case what the limiting possible efficiency would be for any kind of cycle if all heat losses were abolished, it is very necessary, in applying the principle to practical cases, to take account of the possibility of avoiding the heat losses which are supposed to be absent, and of other practical limitations in the working of the actual engine. An immense amount of time and ingenuity has been wasted in striving to realize impossible margins of ideal efficiency, which a close study of the practical conditions would have shown to be illusory. As Carnot remarks at the conclusion of his essay: "Economy of fuel is only one of the conditions a heat-engine must satisfy; in many cases it is only secondary, and must often give way to considerations of safety, strength and wearing qualities of the machine, of smallness of space occupied, or of expense in erecting. To know how to appreciate justly in each case the considerations of convenience and economy, to be able to distinguish the essential from the accessory, to balance all fairly, and finally to arrive at the best result by the simplest means, such must be the principal talent of the man called on to direct and co-ordinate the work of his fellows for the attainment of a useful object of any kind."

TRANSFERENCE OF HEAT

27. There are three principal modes of transference of heat, namely (1) convection, (2) conduction and (3) radiation:

(1) In convection, heat is carried or conveyed by the motion of heated masses of matter. The most familiar illustrations of this method of transference are the heating of buildings by the circulation of steam or hot water, or the equalization of temperature of a mass of unequally heated liquid or gas by convection currents, produced by natural changes of density or by artificial stirring. (2) In conduction, heat is transferred by contact between contiguous particles of matter and is passed on from one particle to the next without visible relative motion of the parts of the body. A familiar illustration of conduction is the passage of heat through the metal plates of a boiler from the fire to the water inside, or the transference of heat from a soldering bolt to the solder and the metal with which it is placed in contact. (3) In radiation, the heated body gives rise to a motion of vibration in the aether, which is propagated equally in all directions, and is reconverted into heat when it encounters any obstacle capable of absorbing it. Thus radiation differs from conduction and convection in taking place most perfectly in the absence of matter, whereas conduction and convection require material communication between the bodies concerned.

In the majority of cases of transference of heat all three modes of transference are simultaneously operative in a greater or less degree, and the combined effect is generally of great complexity. The different modes of transference are subject to widely different laws, and the difficulty of disentangling their effects and subjecting them to calculation is often one of the most serious obstacles in the experimental investigation of heat. In space void of matter, we should have pure radiation, but it is difficult to obtain so perfect a vacuum that the effects of the residual gas in transferring heat by conduction or convection are inappreciable. In the interior of an opaque solid we should have pure conduction, but if the solid is sensibly transparent in thin layers there must also be an internal radiation, while in a liquid or a gas it is very difficult to eliminate the effects of convection. These difficulties are well illustrated in the historical development of the subject by the experimental investigations which have been made to determine the laws of heat-transference, such as the laws of cooling, of radiation and of conduction.

28. **Newton's Law of Cooling.**—There is one essential condition common to all three modes of heat-transference, namely, that they depend on difference of temperature, that the direction of the transfer of heat is always from hot to cold, and that the rate of transference is, for small differences, directly proportional to the difference of temperature. Without difference of temperature

there is no transfer of heat. When two bodies have been brought to the same temperature by conduction, they are also in equilibrium as regards radiation, and vice versa. If this were not the case, there could be no equilibrium of heat defined by equality of temperature. A hot body placed in an enclosure of lower temperature, e.g., a calorimeter in its containing vessel, generally loses heat by all three modes simultaneously in different degrees. The loss by each mode will depend in different ways on the form, extent and nature of its surface and on that of the enclosure, on the manner in which it is supported, on its relative position and distance from the enclosure, and on the nature of the intervening medium. But provided that the difference of temperature is small, the rate of loss of heat by all modes will be approximately proportional to the difference of temperature, the other conditions remaining constant. The rate of cooling or the rate of fall of temperature will also be nearly proportional to the rate of loss of heat, if the specific heat of the cooling body is constant, or the rate of cooling at any moment will be proportional to the difference of temperature.

This simple relation is commonly known as Newton's law of cooling, but is limited in its application to comparatively simple cases such as the foregoing. Newton himself applied it to estimate the temperature of a red-hot iron ball, by observing the time which it took to cool from a red heat to a known temperature, and comparing this with the time taken to cool through a known range at ordinary temperatures. According to this law if the excess of temperature of the body above its surroundings is observed at equal intervals of time, the observed values will form a geometrical progression with a common ratio. Supposing, for instance, that the surrounding temperature were 0°C , that the red-hot ball took 25 minutes to cool from its original temperature to 20°C , and 5 minutes to cool from 20°C to 10°C , the original temperature is easily calculated on the assumption that the excess of temperature above 0°C falls to half its value in each interval of 5 minutes. Doubling the value 20° at 25 minutes five times, we arrive at 640°C as the original temperature. No other method of estimation of such temperatures was available in the time of Newton, but, as we now know, the simple law of proportionality to the temperature difference is inapplicable over such large ranges of temperature. The rate of loss of heat by radiation, and also by convection and conduction to the surrounding air, increases much more rapidly than in simple proportion to the temperature difference, and the rate of increase of each follows a different law. At a later date Sir John Herschel measured the intensity of the solar radiation at the surface of the earth, and endeavoured to form an estimate of the temperature of the sun by comparison with terrestrial sources on the assumption that the intensity of radiation was simply proportional to the temperature difference. He thus arrived at an estimate of several million degrees, which we now know would be about a thousand times too great. The application of Newton's law necessarily leads to absurd results when the difference of temperature is very large, but the error will not in general exceed 2% to 3% if the temperature difference does not exceed 10°C , and the percentage error is proportionately much smaller for smaller differences.

29. **Surface Emissivity.**—Similar considerations apply to many attempts which have been made to determine the general value of the constant termed by Fourier and early writers the "exterior conductivity," but now called the surface emissivity. This coefficient represents the rate of loss of heat from a body per unit area of surface per degree excess of temperature, and includes the effects of radiation, convection and conduction. As already pointed out, the combined effect will be nearly proportional to the excess of temperature in any given case provided that the excess is small, but it is not necessarily proportional to the extent of surface exposed except in the case of pure radiation. The rate of loss of heat by convection and conduction varies with the form of the surface, and, unless the enclosure is very large compared with the cooling body, the effect depends also on the size and form of the enclosure. The effects of conduction and radiation may be approximately estimated if the conductivity of the gas and the nature and forms of the surfaces of the body and enclosure

are known, but the effect of convection in any case can be determined only by experiment. It has been found that the rate of cooling by a current of air is approximately proportional to the velocity of the current, other things being equal. It is obvious that this should be the case, but the result cannot generally be applied to convection currents. Values which are commonly given for the surface emissivity must therefore be accepted with great reserve. They can be regarded only as approximate, and as applicable only to cases precisely similar to those for which they were experimentally obtained. There cannot be said to be any general law of convection. The loss of heat is not necessarily proportional to the area of the surface, and no general value of the coefficient can be given to suit all cases. The laws of conduction and radiation admit of being more precisely formulated, and their effects predicted, except in so far as they are complicated by convection.

CONDUCTION OF HEAT IN SOLIDS

30. The transference of heat in the interior of a solid body formed one of the earliest subjects of mathematical and experimental treatment in the theory of heat. The law assumed by Fourier was of the simplest possible type, but the mathematical application, except in the simplest cases, was so difficult as to require the development of a new mathematical method. Fourier succeeded in showing how, by his method of analysis, the solution of any given problem with regard to the flow of heat by conduction in any material could be obtained in terms of a physical constant, the thermal conductivity of the material, and that the results obtained by experiment agreed in a qualitative manner with those predicted by his theory. But the experimental determination of the actual values of these constants presented formidable difficulties which were not surmounted till a later date.

The law of conduction, which forms the basis of the mathematical theory, although seldom explicitly stated as an experimental law, should really be regarded in this light, and may be briefly worded as follows: "*The rate of transmission of heat by conduction is proportional to the temperature gradient.*" The rate of transmission of heat is here understood to mean the quantity of heat transferred in unit time through unit area of cross-section of the substance, the unit area being taken perpendicular to the lines of flow. It is clear that the quantity transferred in any case must be jointly proportional to the area and the time. The "gradient of temperature" is the fall of temperature in degrees per unit length along the lines of flow.

The *thermal conductivity* of the substance is the constant ratio of the rate of transmission to the temperature gradient. To take the simple case of the "wall" or flat plate considered by Fourier for the definition of thermal conductivity, suppose that a quantity of heat Q passes per second through an area A of a plate of conductivity k and thickness x , the sides of which are constantly maintained at temperatures t_1 and t_2 . The rate of transmission of heat is Q/A , and the temperature gradient, supposed uniform, is $(t_1 - t_2)/x$, so that the law of conduction leads at once to the equation

$$Q/A = k(t_1 - t_2)/x \quad (5)$$

This relation applies accurately to the case of the steady flow of heat in parallel straight lines through a homogeneous and isotropic solid, the isothermal surfaces, or surfaces of equal temperature, being planes perpendicular to the lines of flow. If the flow is steady, and the temperature of each point of the body invariable, the rate of transmission must be everywhere the same. One of the simplest illustrations of the rectilinear flow of heat is the steady outflow through the upper strata of the earth's crust, which may be considered practically plane in this connection. This outflow of heat necessitates a rise of temperature with increase of depth. The corresponding gradient is of the order of 1°C in roof, but varies inversely with the conductivity of the strata at different depths.

A different type of problem is presented in those cases in which the temperature at each point varies with the time, as is the case near the surface of the soil with variations in the external condi-

tions between day and night or summer and winter. The flow of heat may still be linear if the horizontal layers of the soil are of uniform composition, but the quantity flowing through each layer is no longer the same. Part of the heat is used up in changing the temperature of the successive layers. In this case it is generally more convenient to consider as unit of heat the thermal capacity c of unit volume, or that quantity which would produce a rise of one degree of temperature in unit volume of the soil or substance considered. If Q is expressed in terms of this unit in equation (5), it is necessary to divide by c , or to replace k on the right-hand side by the ratio k/c . This ratio determines the rate of diffusion of temperature, and is called the *thermometric conductivity* or, more shortly, the *diffusivity*. The velocity of propagation of temperature waves will be the same under similar conditions in two substances which possess the same diffusivity, although they may differ in conductivity.

31. **Variable-flow Methods.**—In these methods the flow of heat is deduced from observations of the rate of change of temperature with time in a body exposed to known external or boundary conditions. No calorimetric observations are required, but the results are obtained in terms of the thermal capacity of unit volume c , and the measurements give the diffusivity k/c , instead of the calorimetric conductivity k . Since both k and c are generally variable with the temperature, and the mode of variation of either is often unknown, the results of these methods are generally less certain with regard to the actual flow of heat. As in the case of steady-flow methods, by far the simplest example to consider is that of the linear flow of heat in an infinite solid, which is most nearly realized in nature in the propagation of temperature waves in the surface of the soil. One of the best methods of studying the flow of heat in this case is to draw a series of curves showing the variations of temperature with depth in the soil for a series of consecutive days. The curves given in fig. 6 were obtained from the readings of a number of platinum thermometers buried in undisturbed soil in horizontal positions at McGill College, Montreal.

The method of deducing the diffusivity from these curves is as follows:—The total quantity of heat absorbed by the soil per unit area of surface between any two dates, and any two depths, x' and x'' , is equal to c times the area included between the corresponding curves. This can be measured graphically without any knowledge of the law of variation of the surface temperature, or of the laws of propagation of heat waves. The quantity of heat absorbed by the stratum ($x' x''$) in the interval considered can also be expressed in terms of calorimetric conductivity k . The heat transmitted through the plane x is equal per unit area of surface to the product

FIG. 6

of k by the mean temperature gradient (dt/dx) and the interval of time in secs. The mean temperature gradient is found by plotting the curves for each day from the daily observations. The heat absorbed is the difference of the quantities transmitted through the bounding planes of the stratum. We thus obtain the simple equation

$k'(dt'/dx') - k''(dt''/dx'') = c$ (area between curves)/time in sec., (6) by means of which the average value of the diffusivity k/c can be found for any convenient interval of time, at different seasons of the year, in different states of the soil.

For the particular soil in question it was found that the diffusivity varied enormously with the degree of moisture, falling as low as .0010 C.G.S. in the winter for the surface layers, which became extremely dry under the protection of the frozen ice and snow from December to March, but rising to an average of .0060 to .0070 in the spring and autumn. The greater part of the diffusion of heat was certainly due to the percolation of water. On some occasions, owing to the sudden melting of a surface layer of ice and snow, a large quantity of cold water, percolating rapidly, gave for a short time values of the diffusivity as high as .0300. Excluding these exceptional cases, however, the variations of the diffusivity appeared to follow the variations of the seasons with considerable regularity in successive years. The presence of water in the soil always increased the value of k/c , and as it necessarily increased c , the increase of k must have been greater than that of k/c .

32. **Periodic Flow of Heat.**—The foregoing method is perfectly general, and can be applied in any case in which the requisite observations can be taken. A case of special interest and importance is that in which the flow is *periodic*. The general characteristics of such a flow are illustrated in fig. 7, showing the propagation of temperature waves due to diurnal variations in the temperature of the surface. The daily range of temperature of the air and of the surface of the soil was about 20° F. On a sunny day, the temperature reached a maximum about 2 P.M. and a minimum about 5 A.M. As the waves were propagated downwards through the soil the amplitude rapidly diminished, so that at a depth of only 4 in. it was already reduced to about 6° F, and to less than 2° at 10 in. At the same time, the epoch of maximum or minimum was retarded, about 4 hours at 4 in., and nearly 12 hours at 10 in., where the maximum temperature was reached between 1 and 2 A.M. The form of the wave was also changed. At 4 in. the rise was steeper than the fall, at 10 in. the reverse was the case. This is due to the fact that the components of shorter period are more rapidly propagated. For instance, the velocity of propagation of a wave having a period of a day is nearly twenty times as great as that of a wave with a period of one year; but on the

tion for the expansion of the liquid in the long stems is uncertain, and that the holes may serve as channels for percolation, and thus lead to exceptionally high values. The last error is best avoided by employing platinum thermometers buried horizontally. In any case results deduced from the annual wave must be expected to vary in different years according to the distribution of the rainfall, as the values represent averages depending chiefly on the diffusion of heat by percolating water. For this reason observations at different depths in the same locality often give very concordant results for the same period, as the total percolation and the average rate are necessarily nearly the same for the various strata, although the actual degree of wetness of each may vary considerably. The following are a few typical values for sand or gravel deduced from the annual wave in different localities:—

TABLE I.—*Diffusivity of Sandy Soils. C.G.S. Units*

Observer	Soil	Locality	Thermometer	Diffusivity
Kelvin, 1860	Garden sand	Edinburgh	Mercury	.0087
Neumann, 1863	Sandy loam	"	"	.0136
Everett, 1860	Gravel	Greenwich	"	.0125
Ångström, 1861	Sandy clay	Upsala	"	.0057
Ångström, 1861	"	"	"	.0045
Ångström	Coarse sand	"	"	.0094
Rudberg	The same soil, place and instruments	"	"	.0061
Quetelet	reduced for different years	"	"	.0074
Callendar, 1895	Garden sand	Montreal	Platinum	.0036
Rambaut, 1900	Gravel	Oxford	"	.0074

The low value at Montreal is chiefly due to the absence of percolation during the winter. A. A. Rambaut's results were obtained with similar instruments similarly located, but he did not investigate the seasonal variations of diffusivity, or the effect of percolation. It is probable that the coarser soils, permitting more rapid percolation, would generally give higher results. In any case, it is evident that the transmission of heat by percolation would be much greater in porous soils and in the upper layers of the earth's crust than in the lower strata or in solid rocks. It is probable for this reason that the average conductivity of the earth's crust, as deduced from surface observations, is too large; and that estimates of the age of the earth based on such measurements are too low, and require to be raised; they would thereby be brought into better agreement with the conclusions of geologists derived from other lines of argument.

33. **Laboratory Methods.**—Measurements of thermal conductivity present peculiar difficulties on account of the variety of quantities to be observed, the slowness of the process of conduction, the impossibility of isolating a quantity of heat, and the difficulty of exactly realizing the theoretical conditions of the problem. The following are some of the special cases which have been utilized experimentally:—

The "wall" or plate method endeavours to realize the conditions of equation (5), namely, uniform rectilinear flow. Theoretically this requires an infinite plate, or a perfect heat insulator, so that the lateral flow can be prevented or rendered negligible. This condition can generally be satisfied with sufficient approximation with plates of reasonable dimensions. To find the conductivity, it is necessary to measure all the quantities which occur in equation (5) to a similar order of accuracy. The measurement of the temperature gradient in the plate generally presents the greatest difficulties. If the plate is thin, it is necessary to measure the thickness with great care, and it is necessary to assume that the temperatures of the surfaces are the same as those of the media with which they are in contact, since there is no room to insert thermometers in the plate itself. This assumption does not present serious errors in the case of bad conductors, such as glass or wood, but has given rise to large mistakes in the case of metals. The conductivities of thin slices of crystals have been measured by C. H. Lees (*Phil. Trans.*, 1892) by pressing them between plane

Fig. 7

other hand the penetration of the diurnal wave is nearly 20 times less, and the shorter waves die out more rapidly.

Annual Variation.—A similar method has frequently been applied to the study of variations of soil-temperatures by harmonic analysis of the annual waves. But the theory is not strictly applicable, as the phenomena are not accurately periodic, and the state of the soil is continually varying, and differs at different depths, particularly in regard to its degree of wetness. An additional difficulty arises in the case of observations made with long mercury thermometers buried in vertical holes, that the correc-

amalgamated surfaces of metal. This gives very good contact, and the conductivity of the metal being many times that of the crystal, the temperature of the surface is determinate.

Fig. 8 illustrates a modern example of the plate method, and shows how nearly the theoretical conditions can be realized with the aid of thermocouples and electric heating. To make the conditions of heat-flow and heat-loss symmetrical, it is desirable to

FIG. 8.—WALL OR PLATE METHOD OF MEASURING THERMAL CONDUCTIVITY OF ROCK SPECIMEN WITH AID OF THERMO-COUPLES AND ELECTRIC HEATING

employ a pair of similar plates of the material to be tested, which in this case consist of quartzite of comparatively high conductivity, 15 cm. square and 4 cm. thick. The plates specimens are mounted on either side of an electric heater constructed of a pair of nichrome-asbestos mats of 100 ohms each, separated by a pad of asbestos paper, and sandwiched between a pair of gunmetal plates, from which they are insulated by thin sheets of cabinet mica. Thus the heat generated by the electric current is evenly distributed in both directions over the surfaces of the specimens and is fully utilized for maintaining the heat-flow. The outer surfaces of the specimens are cooled by a pair of gunmetal plates, channelled for water circulation, and provided with a steady flow of cooling water at a constant temperature. When the electric current is turned on, a steady flow of heat through the specimens is rapidly established, and is readily determined by observing the volts on the heating mats. Thus with 70 volts on each mat, the total flow through each specimen is 49 watts, equivalent to 0.0522 gm. cal. per sq. cm. per sec. for the value of Q/A in equation (5).

The temperature difference between the hot and cold surfaces of each specimen is measured by a copper-constantan thermocouple with its junctions at the centre of each surface. The wires are rolled to a thinness of 0.02 mm. and are in direct contact with the surfaces of the rock specimens, being insulated from the gunmetal plates by thin sheets of cabinet mica. With 70 volts on each heating mat, the mean of the temperature differences for the two specimens was found to be 14.60° C in a thickness of 4 cm., giving 3.65° C for the temperature gradient. Neglecting any correction for heat-loss the value of the thermal conductivity k comes out 0.0522/3.65 or 0.0143 C.G.S.

In order to stabilize the external loss of heat, the apparatus is enclosed in a double-walled jacket maintained at a constant temperature by the circulating water which also flows through the gunmetal coolers on either side of the specimens. Thus there is no heat-loss from the exposed surface of the coolers. The heat-loss from the exposed sides of the heaters is proportional per sq. cm. to the excess temperature $d\theta$ shown by the hot junction. That from the sides of the rock specimens is proportional to $d\theta/2$ per sq. cm. Since the exposed areas in each case are known, the heat loss from the sides of the heaters and rock specimens can be found if the surface emissivity can be determined. This is easily done by cutting off the circulation of cooling water from the cooling plates, without altering the circulation through the external jacket. A small current then suffices to raise the whole block to a nearly uniform excess of temperature above the jacket, if sufficient time is allowed for the attainment of equilibrium. The assumption of uniform surface emissivity is sufficiently approximate for estimating the small correction for heat-loss provided that the exposed surfaces are all varnished. Thus with 6 watts on each heater it is found that the central plates are raised to an excess temperature $\theta = 14.6^\circ$ above the jacket as in the original experi-

ment. The end plates are raised to $\theta = 13.4^\circ$ in the absence of the water cooling. The sides of the rock specimens are raised to a mean temperature $\theta = 14.0^\circ$. The loss from each heater comes out 0.71 watt at 14.6°, that from each rock specimen, 2.34 watts at 14.0° and that from the end plates 2.95 watts at 13.4°. In the original experiment, the mean temperature of the sides of the rock specimens being only 7.3° above the jacket, the loss would be reduced in the ratio 7.3 to 14.0 and would be 1.22 watt only. The loss from each heater at 14.6° being 0.71 watt, the actual flow of heat through the hot surface of each specimen would be reduced from 70 watts to 69.3, and that through the cold surface of each would be further reduced to 68.1 by the loss from the sides of the specimens. Thus the mean flow through each would be 68.7 watts, the correction for heat-loss amounting to less than 2 per cent of the whole. The corrected value of the conductivity is also reduced by 2 per cent, giving 0.0140 C.G.S. in place of the original value 0.0143 in which heat-loss was neglected.

The most essential precaution in this method of experiment is to use accurately worked specimens with plane surfaces, and to exclude air films which might interfere with the uniform distribution of the heat-flow, since the conductivity of air is about 250 times smaller than that of quartzite, so that a thousandth of an inch of air would be equivalent in resistance to nearly a quarter of an inch of quartzite. A viscous liquid like glycerine is often employed for the purpose of excluding air films, but is apt to give trouble by absorbing moisture and creeping on to the heating mats.

A more satisfactory method is to drop about 1 cu. cm. of paraffin wax on the centre of each plate before building up the block. The block is then built up in a light wooden frame with four uprights grooved to fit the corners of the plates, and a small current is passed through the heaters to melt the wax and allow the plates to settle into contact. After removing the small excess of wax, the current is turned off and the block allowed to cool. This gives a solid block which is easily handled without shifting the plates, and which can be unbuilt in a similar manner when it is desired to use other specimens. Other materials, such as pitch, may be employed for building up the block, when it is desired to work at higher temperatures, such as 100° C with steam in the jacket. The plate method as above described may be employed with suitable modifications for a considerable variety of materials, but is most accurate and convenient in the case of substances of moderate conductivity, such as compact rocks. For good conductors like the metals the temperature gradients are too small and difficult to measure unless either the heat-flow or the heat-loss is excessive. For bad conductors, such as ebonite or cork, it is necessary to use thinner plates. The effective thickness cannot be measured with the same percentage of accuracy, but the results are probably as good as can be obtained by any other method.

Tube Method.—If the inside of a glass tube is exposed to steam, and the outside to a rapid current of water, or *vice versa*, the temperatures of the surfaces of the glass may be taken to be approximately equal to those of the water and steam, which may easily be observed. If the thickness of the glass is small compared with the diameter of the tube, say one-tenth, equation (5) may be applied with sufficient approximation, the area A being taken as the mean between the internal and external surfaces. It is necessary that the thickness x should be approximately uniform. Its mean value may be determined most satisfactorily from the weight and the density. The heat Q transmitted in a given time T may be deduced from an observation of the rise of temperature of the water, and the amount which passes in the interval. This is one of the simplest of all methods in practice, but it involves the measurement of several different quantities, some of which are difficult to observe accurately. Unfortunately the method cannot be applied to good conductors, like the metals, because the difference of temperature between the surfaces may be many times less than that between the water and steam in contact with them, even if the water is energetically stirred. Owing to the error involved in this assumption the values given by some of the early observers for the conductivity of copper were nearly 200 times too small.

Cylinder Method.—A variation of the tube method, which can be applied to metals and good conductors, depends on the employment of a thick cylinder with a small axial hole in place of a thin tube. The actual temperature of the metal itself can then be observed by inserting thermometers or thermo-couples at measured distances from the centre as indicated in the annexed fig. 9. This method has been applied by H. L. Callendar and J. T. Nicolson (*Brit. Assoc. Report*, 1897) to cylinders of cast-iron and mild steel, 5in. in diam. and 2ft. long, with 1in. axial holes. The surface of the central hole was heated by steam under pressure, and the total flow of heat was determined by observing the amount of steam condensed in a given time. The outside of the cylinder was cooled by water circulating round a spiral screw thread in a narrow space with high velocity driven by a pressure of 120lb. per sq.in. A very uniform surface temperature was thus obtained. The lines of flow in this method are radial. The isothermal surfaces are coaxial cylinders. The areas of successive surfaces vary as their radii, hence the rate of transmission Q/A varies inversely as the radius r , and is $Q/2\pi rl$, if l is the length of the cylinder, and Q the heat flow per sec. calculated from the condensation of steam. The outward gradient is dt/dr , and is negative if the central hole is heated. We have therefore the simple equation

$$-kdt/dr = Q/2\pi rl \quad (7)$$

If k is constant the solution is evidently $t = a \log r + b$, where $a = -Q/2\pi kl$, and b and k are determined from the known values of the temperatures observed at any two distances from the axis. This gives an average value of the conductivity over the range, but it is better to observe the temperatures at three distances, and to assume k to be a linear function of the temperature, in which case the solution of the equation is still very simple, namely,

$$t + \frac{1}{2}et^2 = a \log r \times b, \quad (8)$$

where e is the temperature-coefficient of the conductivity. The chief difficulty in this method lay in determining the effective distances of the bulbs of the thermometers from the axis of the cylinder, and in ensuring uniformity of flow of heat along different radii. For these reasons the temperature-coefficient of the conductivity could not be determined satisfactorily on this particular form of apparatus, but the mean results were probably trustworthy to 1 or 2%. They refer to a temperature of about 60° C, and were—

Cast-iron, 0.109; mild steel, 0.119, C.G.S.

34. **Forbes's Bar Method.**—Observation of the steady distribution of temperature along a bar heated at one end was very early employed by Fourier, Despretz and others for the comparison of conductivities. It is the most convenient method, in the case of good conductors, on account of the great facilities which it permits for the measurement of the temperature gradient at different points; but it has the disadvantage that the results depend almost entirely on a knowledge of the external heat loss or emissivity, or, in comparative experiments, on the assumption that it is the same in different cases. The method of Forbes (in which the conductivity is deduced from the steady distribution of temperature on the assumption that the rate of loss of heat at each point of the bar is the same as that observed in an auxiliary experiment in which a short bar of the same kind is set to cool under conditions which are supposed to be identical) is well known, but a consideration of its weak points is very instructive, and the results have been most remarkably misunderstood and misquoted. The method

gives directly, not k , but k/c . P. G. Tait repeated Forbes's experiments, using one of the same iron bars, and endeavoured to correct his results for the variation of the specific heat c . J. C. Mitchell, under Tait's direction, repeated the experiments with the same bar nickel-plated, correcting the thermometers for stem-exposure, and also varying the conditions by cooling one end, so as to obtain a steeper gradient. The results of Forbes, Tait and Mitchell, on the same bar, and Mitchell's two results with the end of the bar "free" and "cooled," have been quoted as if they referred to different metals. This is not very surprising, if the values in the following table are compared:—

TABLE II.—*Thermal Conductivity of Forbes's Iron Bar D (1.25 inches square). C.G.S. Units*

Temp. Cent.	Uncorrected for variation of c				Corrected for variation of c			
	Forbes	Tait	Mitchell		Forbes	Tait	Mitchell	
			Free	Cooled			Free	Cooled
0°	.207	.231	.197	.178	.213	.238	.203	.184
100°	.157	.198	.178	.190	.168	.212	.190	.197
200°	.136	.176	.160	.181	.152	.196	.178	.210

The variation of c is uncertain. The values credited to Forbes are those given by J. D. Everett on Balfour Stewart's authority. Tait gives different figures. The values given in the column headed "cooled" are those found by Mitchell with one end of the bar cooled. The discrepancies are chiefly due to the error of the fundamental assumption that the rate of cooling is the same at the same temperature under the very different conditions existing in the two parts of the experiment. They are also partly caused by the large uncertainties of the corrections, especially those of the mercury thermometers under the peculiar conditions of the experiment. The results of Forbes are interesting historically as having been the first approximately correct determinations of conductivity in absolute value. The same method was applied by R. W. Stewart (*Phil. Trans.*, 1892), with the substitution of thermo-couples (following Wiedemann) for mercury thermometers. This avoids the very uncertain correction for stem-exposure, but it is doubtful how far an insulated couple, inserted in a hole in the bar, may be trusted to attain the true temperature. The other uncertainties of the method remain. R. W. Stewart found for pure iron, $k = .175$ ($1 - .0015 t$) C.G.S. E. H. Hall using a similar method found for cast-iron at 50° C the value .105, but considers the method very uncertain as ordinarily practised.

Calorimetric Bar Method.—To avoid the uncertainties of surface loss of heat, it is necessary to reduce it to the rank of a small

FIG. 10.—CALORIMETRIC BAR METHOD, IN WHICH HEAT-FLOW IS MEASURED BY RISE OF TEMPERATURE OF COOLING WATER, GRADIENT BY MERCURY THERMOMETERS: APPARATUS ALSO USED FOR ÅNGSTRÖM'S PERIODIC-FLOW METHOD

correction by employing a large bar and protecting it from loss of heat. The heat transmitted should be measured calorimetrically, and not in terms of the uncertain emissivity. The apparatus shown in fig. 10 was constructed by Callendar and Nicolson with this object. The bar was a special sample of cast-iron, the conductivity of which was required for some experiments on the condensation of steam (*Proc. Inst. C.E.*, 1898). It had a diameter of 4in., and a length of 4ft. between the heater and the calorimeter. The emissivity was reduced to one-quarter by lagging the bar like a steam-pipe to a thickness of 1in. The heating vessel could be maintained at a steady temperature by high-pressure steam. The other end was maintained at a temperature near that

of the air by a steady stream of water flowing through a well-lagged vessel surrounding the bar. The heat transmitted was measured by observing the difference of temperature between the inflow and the outflow, and the weight of water which passed in a given time. The gradient near the entrance to the calorimeter was deduced from observations with five thermometers at suitable intervals along the bar. The results obtained by this method at a temperature of 40°C varied from .116 to .118 C.G.S. from observations on different days, and were probably more accurate than those obtained by the cylinder method. The same apparatus was employed in another series of experiments by the periodic flow method, but this involves a knowledge of c , and is very laborious.

35. Electrical Methods.—There are two electrical methods which have been recently applied to the measurement of the conductivity of metals, (a) the resistance method, devised by Callendar, and applied by him, and also by R. O. King and J. D. Duncan, (b) the thermo-electric method, devised by Kohlrausch, and applied by W. Jaeger and H. Dieselhorst. Both methods depend on the observation of the steady distribution of temperature in a bar or wire heated by an electric current. The advantage is that the quantities of heat are measured directly in absolute measure, in terms of the current, and that the results are independent of a knowledge of the specific heat. Incidentally it is possible to regulate the heat supply more perfectly than in non-electric methods.

(a) In the practice of the resistance method, both ends of a short bar are kept at a steady temperature by means of solid copper blocks provided with a water circulation, and the whole is surrounded by a jacket at the same temperature, which is taken as the zero of reference. The bar is heated by a steady electric current, which may be adjusted so that the external loss of heat from the surface of the bar is compensated by the increase of resistance of the bar with rise of temperature. In this case the curve representing the distribution of temperature is a parabola, and the conductivity k is deduced from the mean rise of temperature $(R-R_0)/aR_0$ by observing the increase of resistance $R-R_0$ of the bar, and the current C . It is also necessary to measure the cross-section q , the length l , and the temperature-coefficient α for the range of the experiment.

In the general case the distribution of temperature is observed by means of a number of potential leads. The differential equation for the distribution of temperature in this case includes the majority of the methods already considered, and may be stated as follows. The heat generated by the current C at a point x , where θ =excess temperature, is equal per unit length and time (t) to that lost by conduction $-d(qk d\theta/dx)/dx$, and by radiation $hp\theta$ (emissivity h , perimeter p), together with that employed in raising the temperature $qcd\theta/dt$, and absorbed by the Thomson effect $Cd\theta/dx$. We thus obtain the equation

$$C^2R_0(1+\alpha\theta)/l = -d(qk d\theta/dx)/dx + hp\theta + qcd\theta/dt + sCd\theta/dx. \quad (9)$$

If $C=0$, this is the equation of Ångström's method. If h also is zero, it becomes the equation of variable flow in the soil. If $d\theta/dt=0$, the equation represents the corresponding cases of steady flow. In the electrical method, observations of the variable flow are useful for finding the value of c for the specimen, but are not otherwise required. The last term, representing the Thomson effect, is eliminated in the case of a bar cooled at both ends, since it is opposite in the two halves, but may be determined by observing the resistance of each half separately. If the current C is chosen so that $C^2R_0\alpha=hlpl$, the external heat-loss is compensated by the variation of resistance with temperature. In this case the solution of the equation reduces to the form

$$\theta = x(l-x)C^2R_0/2lqk. \quad (10)$$

By a property of the parabola, the mean temperature is two-thirds of the maximum temperature; we have therefore

$$(R-R_0)/aR_0 = lC^2R_0/12qk, \quad (11)$$

which gives the conductivity directly in terms of the quantities actually observed. If the dimensions of the bar are suitably

chosen, the distribution of temperature is always very nearly parabolic, so that it is not necessary to determine the value of the critical current $C^2=hlpl/aR_0$ very accurately, as the correction for external loss is a small percentage in any case. The chief difficulty is that of measuring the small change of resistance accurately, and of avoiding errors from accidental thermo-electric effects. In addition to the simple measurements of the conductivity (M'Gill College, 1895-1896), some very elaborate experiments were made by King (*Proc. Amer. Acad.*, June 1898) on the temperature distribution in the case of long bars with a view to measuring the Thomson effect. Duncan (*M'Gill College Reports*, 1899), using the simple method under King's supervision, found the conductivity of very pure copper to be 1.007 for a temperature of 33°C .

(b) The method of Kohlrausch, as carried out by Jaeger and Dieselhorst (*Berlin Acad.*, July 1899), consists in observing the difference of temperature between the centre and the ends of the bar by means of insulated thermo-couples. Neglecting the external heat-loss, and the variation of the thermal and electric conductivities k and k' , we obtain, as before, for the difference of temperature between the centre and ends, the equation

$$\theta_{max}-\theta_0 = C^2Rl/8qk = ECl/8qk = E^2k'/8k, \quad (12)$$

where E is the difference of electric potential between the ends. Lorenz, assuming that the ratio $k/k'=a\theta$, had previously given

$$\theta_{max}^2-\theta_0^2 = E^2/4a, \quad (13)$$

which is practically identical with the preceding for small differences of temperature. The last expression in terms of k/k' is very simple, but the first is more useful in practice, as the quantities actually measured are E , C , l , q , and the difference of temperature. The current C was measured in the usual way by the difference of potential on a standard resistance. The external heat-loss was estimated by varying the temperature of the jacket surrounding the bar, and applying a suitable correction to the observed difference of temperature. But the method (a) previously described appears to be preferable in this respect, since it is better to keep the jacket at the same temperature as the end-blocks. Moreover, the variation of thermal conductivity with temperature is small and uncertain, whereas the variation of electrical conductivity is large and can be accurately determined, and may therefore be legitimately utilized for eliminating the external heat-loss.

One of the chief objects of these experiments was to test the combined hypotheses of G. Wiedemann (1853) and L. Lorenz (1872), that the ratio of the thermal to the electrical conductivity was the same for all metals, and varied directly as the absolute temperature. This relation was strongly supported as a result of the development of the electron theory of conduction in metals by Drude (1900) and H. A. Lorentz (1905), and was approximately verified for some of the pure metals by Jaeger and Dieselhorst between 0° and 100°C . But the ratio appears to be affected in a marked degree by the presence of impurities which reduce the electric conductivity, and the majority of alloys give much higher values than the pure metals. It has since been shown by the experiments of Lees (1908), Onnes (1914) and Meissner (1920), that the remarkable increase of electric conductivity of some pure metals at very low temperatures does not extend to the thermal conductivity. Sir J. J. Thomson in his *Corpuscular Theory of Matter* (1907) had already pointed out that there were serious difficulties in the electron theory of Drude and Lorentz, and proposed an alternative theory which did not require the presence of a large number of free electrons in the metal. This was further developed (*Proc. Phys. Soc.* 1915) and appears to supply a reasonable explanation of the increase of electric conductivity at very low temperatures without requiring a similar increase of thermal conductivity. There is no doubt a general parallelism between thermal and electric conductivity in the case of pure metals, but the conditions are so different in many ways that one could not expect any simple and exact relation to hold generally.

CONDUCTION IN GASES AND LIQUIDS

36. The theory of conduction of heat by diffusion in gases has a particular interest, since it is possible to predict the value of the

conductivity on certain assumptions, if the viscosity is known. On the kinetic theory the molecules of a gas are relatively far apart and there is nothing exactly analogous to friction between two adjacent layers A and B in relative motion. There is, however, a continual interchange of molecules between A and B, which produces the same effect as viscosity in a liquid. Faster-moving particles diffusing from A to B carry their momentum with them, and tend to accelerate B; an equal number of slower particles diffusing from B to A act as a drag on A. This action and reaction between layers in relative motion is equivalent to a frictional stress tending to equalize the velocities of adjacent layers. The magnitude of the stress per unit area parallel to the direction of flow is evidently proportional to the velocity gradient, or the rate of change of velocity per cm. in passing from one layer to the next. It must also depend on the rate of interchange of molecules, that is to say, (1) on the number passing through each square centimetre per second in either direction, (2) on the average distance to which each can travel before collision (*i.e.* on the "mean free path"), and (3) on the average velocity of translation of the molecules, which varies as the square root of the temperature. Similarly if A is hotter than B, or if there is a gradient of temperature between adjacent layers, the diffusion of molecules from A to B tends to equalize the temperatures, or to conduct heat through the gas at a rate proportional to the temperature gradient, and depending also on the rate of interchange of molecules in the same way as the viscosity effect.

Conductivity and viscosity in a gas should vary in a similar manner since each depends on diffusion in a similar way. The mechanism is the same, but in one case we have diffusion of momentum, in the other case diffusion of heat. Viscosity in a gas was first studied theoretically from this point of view by J. Clerk Maxwell, who predicted that the effect should be independent of the density within wide limits. This, at first sight, paradoxical result is explained by the fact that the mean free path of each molecule increases in the same proportion as the density is diminished, so that as the number of molecules crossing each square centimetre decreases, the distance to which each carries its momentum increases, and the total transfer of momentum is unaffected by variation of density. Maxwell himself verified this prediction experimentally for viscosity over a wide range of pressure. By similar reasoning the thermal conductivity of a gas should be independent of the density. Maxwell predicted a value 0.000055 C.G.S. for the conductivity of air, and a value seven times greater for hydrogen on account of the greater velocity and range of its molecules. A. Kundt and E. Warburg (*Jour. Phys.*, v. 118) found that the rate of cooling of a thermometer in air between 150 mm. and 1 mm. pressure remained constant as the pressure was varied. At higher pressures the effect of conduction was masked by convection currents.

The question of the variation of conductivity with temperature is more difficult. If the effects depended merely on the velocity of translation of the molecules, both conductivity and viscosity should increase directly as the square root of the absolute temperature; but the mean free path also varies in a manner which cannot be predicted by theory and which appears to be different for different gases (Rayleigh, *Proc. R.S.*, January 1896). Experiments by the capillary tube method have shown that the viscosity varies more nearly as $\theta^{\frac{1}{2}}$, but indicate that the rate of increase diminishes at high temperatures. The conductivity probably changes with temperature in the same way, being proportional to the product of the viscosity and the specific heat; but the experimental investigation presents difficulties on account of the necessity of eliminating the effects of radiation and convection, and the results of different observers often differ considerably from theory and from each other. The values found for the conductivity of air at 0° C range from .000048 to .000057, and the temperature-coefficient from .0015 to .0028.

Experimental determinations of the thermal conductivities of gases are still somewhat scarce and discordant owing to the great practical difficulties, but are of special interest for the elucidation of the law of action between molecules. The hot-wire method of T. Andrews (*Phil. Trans.*, 1840) offers special facilities for rela-

tive measurements, such as the comparison of conductivities of different gases, or of the same gas at different temperatures, and has frequently been applied with this object in recent years. It has also been improved by introducing the usual compensation for end-effects, and employing more accurate methods of electrical measurement, but it remains liable to the difficulties depending on the small dimensions of the wire and the elimination of the corrections for radiation. The determination of the thermal conductivities of gases gives a means of testing the value of the numerical coefficient f in the relation, $k=f\eta s$, between the conductivity k , the viscosity η , and the specific heat s at constant volume. According to the theoretical investigations of S. Chapman (*Phil. Trans.*, A, 211, p. 433, 1911) the value of the coefficient f should be 2.5 for a gas constituted of spherically symmetrical molecules, which agrees with Maxwell's theory based on the inverse fifth-power law of force, and also with experiment for monatomic molecules. Unfortunately the variation of viscosity with temperature does not satisfy the fifth-power law, which requires that the viscosity should be directly proportional to T . The conclusion is that monatomic gases may have spherically symmetrical molecules, but that the law of force is different. Theory gives no clear indication with regard to the appropriate value of f for other types of molecules. Experiment gives approximately a linear relation, $f=2.816\gamma-2.2$, between f and the ratio γ of the specific heats. This gives $f=7/4$ for diatomic gases, which show fair agreement with each other. The experimental values for polyatomic gases are much less certain.

The thermal conductivity of liquids shows in one respect a remarkable contrast to that of gases, in that it has little or no relation to the viscosity. Excluding liquid metals, different liquids, such as water and glycerine, may vary widely in viscosity and yet differ little in conductivity. Most liquids show a very rapid diminution of viscosity with rise of temperature, without any corresponding change of similar magnitude in conductivity. But the experimental evidence is very discordant, as in the case of gases. The conductivity of liquids has been investigated by similar methods, generally variations of the thin plate or guard-ring method. A critical account of the subject is contained in a paper by C. Chree (*Phil. Mag.*, July 1887). Many of the experiments were made by comparative methods, taking a standard liquid such as water for reference. A determination of the conductivity of water by S. R. Milner and A. P. Chattock, employing an electrical method, deserves mention on account of the careful elimination of various errors (*Phil. Mag.*, July 1899). Their final result was $k=.001433$ at 20° C, which may be compared with the results of other observers, G. Lundquist (1869), .00155 at 40° C; A. Winkelmann (1874), .00104 at 15° C; H. F. Weber (corrected by H. Lorberg), .00138 at 4° C, and .00152 at 23.6° C; C. H. Lees (*Phil. Trans.*, 1898), .00136 at 25° C, and .00120 at 47° C; C. Chree, .00124 at 18° C, and .00136 at 19.5° C. The variations of these results illustrate the experimental difficulties. It appears probable that the conductivity of a liquid increases with rise of temperature, although the contrary would appear from the work of Lees.

RADIATION

37. It was at one time supposed that there were three distinct kinds of radiation—thermal, luminous and actinic, combined in the radiation from a luminous source such as the sun or a flame. The first gave rise to heat, the second to light and the third to chemical action. The three kinds were partially separated by a prism, the actinic rays being generally more refracted, and the thermal rays less refracted than the luminous. This conception arose very naturally from the observation that the feebly luminous blue and violet rays produced the greatest photographic effects, which also showed the existence of dark rays beyond the violet, whereas the brilliant yellow and red were practically without action on the photographic plate. A thermometer placed in the blue or violet showed no appreciable rise of temperature, and even in the yellow the effect was hardly discernible. The effect increased rapidly as the light faded towards the extreme red, and reached a maximum beyond the extreme limits of the spectrum (Herschel), showing that the greater part of the thermal radiation

was altogether non-luminous.

It is now a commonplace that chemical action, colour sensation and heat are merely different effects of one and the same kind of radiation, the particular effect produced in each case depending on the frequency and intensity of the vibration, and on the nature of the substance on which it falls. When radiation is completely absorbed by a black substance, it is converted into heat, the quantity of heat produced being equivalent to the total energy of the radiation absorbed, irrespective of the colour or frequency of the different rays. The actinic or chemical effects, on the other hand, depend essentially on some relation between the period of the vibration and the properties of the substance acted on. The rays producing such effects are generally those which are most strongly absorbed. The spectrum of chlorophyll, the green colouring matter of plants, shows two very strong absorption bands in the red. The red rays of corresponding period are found to be the most active in promoting the growth of the plant. The chemically active rays are not necessarily the shortest. Even photographic plates may be made to respond to the red rays by staining them with pinachrome or some other suitable dye. The action of light rays on the retina is closely analogous to the action on a photographic plate. The retina, like the plate, is sensitive only to rays within certain restricted limits of frequency. The limits of sensitiveness of each colour sensation are not exactly defined, but vary slightly from one individual to another, especially in cases of partial colour-blindness, and are modified by conditions of fatigue. We are not here concerned with these important physiological and chemical effects of radiation, but rather with the question of the conversion of energy of radiation into heat, and with the laws of emission and absorption of radiation in relation to temperature. We may here also assume the identity of visible and invisible radiations from a heated body in all their physical properties.

It has been abundantly proved that the invisible rays, like the visible, (1) are propagated in straight lines in homogeneous media; (2) are reflected and diffused from the surface of bodies according to the same law; (3) travel with the same velocity in free space, but with slightly different velocities in denser media, being subject to the same law of refraction; (4) exhibit all the phenomena of diffraction and interference which are characteristic of wave-motion in general; (5) are capable of polarization and double refraction; (6) exhibit similar effects of selective absorption. These properties are more easily demonstrated in the case of visible rays on account of the great sensitiveness of the eye. But with the aid of the thermopile or other sensitive radiometer, they may be shown to belong equally to all the radiations from a heated body, even such as are 30 to 50 times slower in frequency than the longest visible rays. The same physical properties have also been shown to belong to electromagnetic waves excited by an electric discharge, whatever the frequency, thus including all kinds of aethereal radiation in the same category as light.

38. Theory of Exchanges.—The apparent concentration of cold by a concave mirror, observed by G. Baptista Porta and rediscovered by M. A. Pictet, led to the enunciation of the theory of exchanges by Pierre Prevost in 1791. Prevost's leading idea was that all bodies, whether cold or hot, are constantly radiating heat. Heat equilibrium, he says, consists in an equality of exchange. When equilibrium is interfered with, it is re-established by inequalities of exchange. If into a locality at uniform temperature a refracting or reflecting body is introduced, it has no effect in the way of changing the temperature at any point of that locality. A reflecting body, heated or cooled in the interior of such an enclosure, will acquire the surrounding temperature more slowly than would a non-reflector, and will less affect another body placed at a little distance, but will not affect the final equality of temperature. Apparent radiation of cold, as from a block of ice to a thermometer placed near it, is due to the fact that the thermometer being at a higher temperature sends more heat to the ice than it receives back from it. Although Prevost does not make the statement in so many words, it is clear that he regards the radiation from a body as depending only on its own nature

and temperature, and as independent of the nature and presence of any adjacent body.

Heat equilibrium in an enclosure of constant temperature such as that postulated by Prevost, has often been regarded as a consequence of Carnot's principle. Since difference of temperature is required for transforming heat into work, no work could be obtained from heat in such a system, and no spontaneous changes of temperature can take place, as any such changes might be utilized for the production of work. This line of reasoning does not appear quite satisfactory, because it is tacitly assumed, in the reasoning by which Carnot's principle was established, as a result of universal experience, that a number of bodies within the same impervious enclosure, which contains no source of heat, will ultimately acquire the same temperature, and that difference of temperature is required to produce flow of heat. Thus although we may regard the equilibrium in such an enclosure as being due to equal exchanges of heat in all directions, the equal and opposite streams of radiation annul and neutralize each other in such a way that no actual transfer of energy in any direction takes place. The state of the medium is everywhere the same in such an enclosure, but its energy of agitation per unit volume is a function of the temperature, and is such that it would not be in equilibrium with any body at a different temperature.

39. "Full" and Selective Radiation.—*Correspondence of Emission and Absorption.* The most obvious difficulties in the way of this theory arise from the fact that nearly all radiation is more or less selective in character, as regards the quality and frequency of the rays emitted and absorbed. It was shown by J. Leslie, M. Melloni and other experimentalists that many substances such as glass and water, which are very transparent to visible rays, are extremely opaque to much of the invisible radiation of lower frequency; and that polished metals, which are perfect reflectors, are very feeble radiators as compared with dull or black bodies at the same temperature. If two bodies emit rays of different periods in different proportions, it is not at first sight easy to see how their radiations can balance each other at the same temperature.

The key to all such difficulties lies in the fundamental conception, so strongly insisted on by Balfour Stewart, of the absolute uniformity (qualitative as well as quantitative) of the full or complete radiation stream inside an impervious enclosure of uniform temperature. It follows from this conception that the proportion of the full radiation stream absorbed by any body in such an enclosure must be exactly compensated in quality as well as quantity by the proportion emitted, or that the emissive and absorptive powers of any body at a given temperature must be precisely equal. A good reflector, like a polished metal, must also be a feeble radiator and absorber. Of the incident radiation it absorbs a small fraction and reflects the remainder, which together with the radiation emitted (being precisely equal to that absorbed) makes up the full radiation stream. A partly transparent material, like glass, absorbs part of the full radiation and transmits part. But it emits rays precisely equal in quality and intensity to those which it absorbs, which together with the transmitted portion make up the full stream.

A thin platinum tube heated by an electric current appears feebly luminous as compared with a blackened tube at the same temperature. But if a small hole is made in the side of the polished tube, the light proceeding through the hole appears brighter than the blackened tube, as though the inside of the tube were much hotter than the outside, which is not the case to any appreciable extent if the tube is thin. The radiation proceeding through the hole is nearly that of a perfectly black body if the hole is small. If there were no hole the internal stream of radiation would be exactly that of a black body at the same temperature however perfect the reflecting power, or however low the emissive power of the walls, because the defect in emissive power would be exactly compensated by the internal reflection.

Balfour Stewart gave a number of striking illustrations of the qualitative identity of emission and absorption of a substance. Pieces of coloured glass placed in a fire appear to lose their colour when at the same temperature as the coals behind them, because

they compensate exactly for their selective absorption by radiating chiefly those colours which they absorb. Rocksalt is remarkably transparent to thermal radiation of nearly all kinds, but it is extremely opaque to radiation from a heated plate of rock-salt, because it emits when heated precisely those rays which it absorbs. A plate of tourmaline cut parallel to the axis absorbs almost completely light polarized in a plane parallel to the axis, but transmits freely light polarized in a perpendicular plane. When heated its radiation is polarized in the same plane as the radiation which it absorbs. In the case of incandescent vapours, the exact correspondence of emission and absorption as regards wave-length or frequency of the light emitted and absorbed forms the foundation of the science of spectrum analysis. Fraunhofer had noticed the coincidence of a pair of bright yellow lines seen in the spectrum of a candle flame with the dark D lines in the solar spectrum, a coincidence which was afterwards more exactly verified by W. A. Miller. Foucault found that the flame of the electric arc showed the same lines bright in its spectrum, and proved that they appeared as dark lines in the otherwise continuous spectrum when the light from the carbon poles was transmitted through the arc. Stokes gave a dynamical explanation of the phenomenon and illustrated it by the analogous case of resonance in sound. Kirchhoff completed the explanation (*Phil. Mag.*, 1860) of the dark lines in the solar spectrum by showing that the reversal of the spectral lines depended on the fact that the body of the sun giving the continuous spectrum was at a higher temperature than the absorbing layer of gases surrounding it.

Whatever be the nature of the selective radiation from a body, the radiation of light of any particular wave-length cannot be greater than a certain fraction E of the radiation R of the same wave-length from a black body at the same temperature. The fraction E measures the emissive power of the body for that particular wave-length, and cannot be greater than unity. The same fraction, by the principle of equality of emissive and absorptive powers, will measure the proportion absorbed of incident radiation R' . If the black body emitting the radiation R' is at the same temperature as the absorbing layer, $R=R'$, the emission balances the absorption, and the line will appear neither bright nor dark. If the source and the absorbing layer are at different temperatures, the radiation absorbed will be ER' , and that transmitted will be $R'-ER'$. To this must be added the radiation emitted by the absorbing layer, namely ER , giving $R'-E(R'-R)$. The lines will appear darker than the background R' if R' is greater than R , but bright if the reverse is the case. The D lines are dark in the sun because the photosphere is much hotter than the reversing layer. They appear bright in the candle-flame because the outside mantle of the flame, in which the sodium burns and combustion is complete, is hotter than the inner reducing flame containing the incandescent particles of carbon which give rise to the continuous spectrum. This qualitative identity of emission and absorption as regards wave-length can be most exactly and easily verified for luminous rays, and we are justified in assuming that the relation holds with the same exactitude for non-luminous rays, although in many cases the experimental proof is less complete and exact.

40. Relation Between Radiation and Temperature.—Assuming, in accordance with the reasoning of Balfour Stewart and Kirchhoff, that the radiation stream inside an impervious enclosure at a uniform temperature is independent of the nature of the walls of the enclosure, and is the same for all substances at the same temperature, it follows that the full stream of radiation in such an enclosure, or the radiation emitted by an ideal black body or full radiator, is a function of the temperature only. The form of this function may be determined experimentally by observing the radiation between two black bodies at different temperatures, which will be proportional to the difference of the full radiation streams corresponding to their several temperatures. The law now generally accepted was first proposed by Stefan as an empirical relation.

Tyndall had found that the radiation from a white hot platinum wire at 1,200° C was 11.7 times its radiation when dull red at 525° C. Stefan (*Wien. Akad. Ber.*, 1879, 79, p. 421) noticed

that the ratio 11.7 is nearly that of the fourth powers of the absolute temperatures as estimated by Tyndall. On making the somewhat different assumption that the radiation between two bodies varied as the difference of the fourth powers of their absolute temperatures, he found that it satisfied approximately the experiments of Dulong and Petit and other observers. According to this law the radiation between a black body at a temperature T and a black enclosure or a black radiometer at a temperature T_0 should be proportional to $(T^4 - T_0^4)$. The law was very simple and convenient in form, but it rested so far on very insecure foundations. The temperatures given by Tyndall were merely estimated from the colour of the light emitted, and might have been some hundred degrees in error. We now know that the radiation from polished platinum is of a highly selective character, and varies more nearly as the fifth power of the absolute temperature. The agreement of the fourth power law with Tyndall's experiment appears therefore to be due to a purely accidental error in estimating the temperatures of the wire. Stefan also found a very fair agreement with Draper's observations of the intensity of radiation from a platinum wire, in which the temperature of the wire was deduced from the expansion. Here again the apparent agreement was largely due to errors in estimating the temperature, arising from the fact that the coefficient of expansion of platinum increases considerably with rise of temperature.

So far as the experimental results available at that time were concerned, Stefan's law could be regarded only as an empirical expression of doubtful significance. But it received a much greater importance from theoretical investigations which were even then in progress. James Clerk Maxwell (*Electricity and Magnetism*, 1873) had shown that a directed beam of electromagnetic radiation or light incident normally on an absorbing surface should produce a mechanical pressure equal to the energy of the radiation per unit volume. A. G. Bartoli (1875) took up this idea and made it the basis of a thermodynamic treatment of radiation. P. N. Lebedew in 1900, and E. F. Nichols and G. F. Hull in 1901, proved the existence of this pressure by direct experiments. L. Boltzmann (1884) employing radiation as the working substance in a Carnot cycle, showed that the energy of full radiation at any temperature per unit volume should be proportional to the fourth power of the absolute temperature.

The proof given by Boltzmann may be somewhat simplified if we observe that full radiation in an enclosure at constant temperature behaves exactly like a saturated vapour, and must therefore obey Carnot's or Clapeyron's equation (see THERMODYNAMICS). The radiation-pressure at any temperature is a function of the temperature only, like the pressure of a saturated vapour. If the volume of the enclosure is increased by any finite amount, the temperature remaining the same, radiation is given off from the walls so as to fill the space to the same pressure as before. The heat absorbed when the volume is increased corresponds with the latent heat of vaporization. In the case of radiation, as in the case of a vapour, the latent heat consists partly of internal energy of formation and partly of external work of expansion at constant pressure. Since in the case of full or undirected radiation the pressure is one-third of the energy per unit volume, the external work for any expansion is one-third of the internal energy added. The latent heat absorbed is, therefore, four times the external work of expansion. Since the external work is the product of the pressure P and the increase of volume V , the latent heat per unit increase of volume is four times the pressure. But by Carnot's equation the latent heat of a saturated vapour per unit increase of volume is equal to the rate of increase of saturation-pressure per degree divided by Carnot's function or multiplied by the absolute temperature. Expressed in symbols we have,

$$T(dP/dT) = L/V = 4P, \quad (14)$$

where (dP/dT) represents the rate of increase of pressure. This equation shows that the percentage rate of increase of pressure is four times the percentage rate of increase of temperature, or that if the temperature is increased by 1%, the pressure is increased by 4%. This is equivalent to the statement that the pressure varies as the fourth power of the temperature, a result which is

mathematically deduced by integrating the equation.

41. Experimental Verification of the Fourth Power Law.

—The verification of this law requires (1) a black body or bodies capable of emitting full radiation at a series of different temperatures over an extended range, (2) a thermometer or thermometers capable of measuring these temperatures on the absolute scale, (3) a bolometer or thermopile capable of giving accurate relative values of the intensity of the radiation emitted in each case. These conditions were approximately satisfied by the experiments of Schneebeli (*Wied. Ann.*, 1884), who employed an air thermometer heated to various temperatures in a furnace, and observed the radiation from the bulb through a small aperture in the walls of the furnace. With this arrangement the radiation observed would be nearly that of a black body, but the verification was rather rough in some respects. Measurements by J. T. Bottomley, A. Schleiermacher, L. C. H. F. Paschen and others, of the radiation from electrically heated platinum, failed to give results in agreement with the fourth power law on account of variations in the quality of the radiation, but greatly extended and improved methods of measuring radiation in other respects.

The most complete series of experiments, covering the range of the gas thermometer at the time available, were those of O. R. Lummer and E. Pringsheim (*Ann. Phys.*, 1897). They used a black body heated by steam at 100° C, for standardizing their bolometer, and, as their radiator, a black body consisting of a copper sphere heated in a salt bath for the range 200° to 600° C, and an iron cylinder heated in a gas muffle for the range 600° to 1,250° C. The temperatures were taken with a high range mercury thermometer, and with thermocouples, corrected to the gas-scale by direct comparison with a gas thermometer up to 1,150° C. One of the chief experimental difficulties of this investigation is the wide range of variation of the intensity of the radiation to be measured, which is nearly 450 times as great at 1,250° C as at 100° C. They employed a very sensitive form of bolometer (see § 42), and a galvanometer capable of giving a deflection of 336mm. under standard conditions, with a beam of radiation 16mm. square at a distance of 633mm. from the black body at 100° C. For the higher intensities it was necessary to reduce the sensitivity in a known ratio by varying the distance of the bolometer from the source, and the current in the bolometer circuit. The results for the relative intensities agreed on the average to about 1% with the fourth power law over the whole range of the observations. The law has since been verified up to 1,500° C by extending the range of the gas thermometer and the calibration of the thermocouples.

42. **Sensitive Radiometers.**—The term radiometer may be applied to any instrument adapted for measuring radiation, but we are here concerned chiefly with those types which are equally sensitive to radiant energy of all the wavelengths present in the radiation from a hot body. We may therefore omit the selenium cell which is very sensitive to luminous radiation, and the photoelectric cell for actinic rays, since these are comparatively insensitive to the infra-red rays, and do not satisfy the condition of measuring total energy irrespective of wavelength. The instruments chiefly employed at the present time for measurements of heat radiation, are the *thermopile* and the *bolometer*, the action of which depends on the same principles as those involved in the construction and operation of the corresponding types of electrical thermometers, namely the thermocouple and the electrical resistance thermometer, the theory of which is more fully discussed in the article THERMOMETRY. The thermopile and bolometer are in fact essentially electrical thermometers, with sensitive receiving surfaces for the absorption of radiation, and especially designed for measuring the small differences of temperature thereby produced. The sensitivity and accuracy of these instruments depend to a great extent on the galvanometer and electrical measuring apparatus with which they are employed.

One of the oldest and most sensitive radiometers is the *Melloni thermopile*, the invention of which led to so many advances in the theory and measurement of radiation. Sensitivity is secured by using antimony and bismuth alloys (A and B), a single couple of which may give as much as 120 microvolts for a difference of

temperature of 1° C between the hot and cold junctions. With 100 couples connected in a continuous series A-B-A-B-A and so on, packed as usual in the form of a cube with alternate junctions on opposite faces, an electromotive force of 12 millivolts would be obtainable per 1° C difference of temperature between the receiving surfaces of the pile. The chief defect of this type of instrument in practice is that it has a large thermal capacity owing to its massive construction, and takes a long time to reach its maximum temperature. For many purposes quickness of action is quite as important as sensitivity in millivolts per degree, and the accuracy obtainable depends to a great extent on constancy of zero. In such cases the Melloni pile will be a most unsuitable instrument to employ, though it is still often used for demonstration purposes.

The conditions affecting quickness and constancy were first clearly elucidated by C. V. Boys (*Phil. Trans.* 1888) in the construction of his *radiomicrometer*, in which the thermopile and galvanometer were combined in a single instrument. This was effected by attaching a very light A-B couple to a loop of copper wire suspended between the poles of a powerful magnet by means of a fine quartz fibre, which made it possible to combine the advantage of maximum deflection for weak sources of radiation with quickness of action and constancy of zero. A similar arrangement was adopted some years later by W. Duddell in his *thermo-galvanometer*, for measuring small alternating currents. The current to be measured is passed through a small heater fixed close below the suspended thermocouple, the deflections of which are approximately proportional to the square of the current. The radio-micrometer is essentially the same instrument except that the suspended thermocouple is heated by radiation incident on a blackened disc of copper or silver foil, and that its constant is determined by exposure to a known source of radiation, such as a standard candle at a considerable distance. The instrument must be set up like a sensitive galvanometer and carefully levelled on a good foundation in a permanent position, and the radiation to be measured must be brought to the receiver in a horizontal direction. In this respect the combination of the thermopile and sensitive galvanometer in a single instrument is less convenient in practice than the use of a separate thermopile in conjunction with a fixed galvanometer, since in the latter case the thermopile can be adjusted in any desired position independently of the galvanometer, and the sensitivity may easily be altered in a known ratio according to requirements by varying the resistance in the circuit without changing the position of either source or receiver.

The *bolometer* invented by S. P. Langley (*Proc. Amer. Acad.*, 1881) depends for its action on change of electrical resistance, and consists essentially of a pair of grids of thin blackened foil of nearly equal resistance balanced one against the other in a Wheatstone bridge. Both are equally affected by changes in the temperature of the instrument, but if one grid is exposed to radiation while the other is screened, the resulting difference of temperature between them produces a current through the galvanometer approximately proportional to the intensity of the radiation. The whole exposed area of the grid constitutes the receiving surface, and extreme quickness of action can be secured by using very thin foil. The bolometer permits a wide range of variation of sensitivity since (in addition to other methods available with the thermopile) the current through the grids may be increased with a proportional increase in the deflection of the galvanometer. For this reason the sensitivity of a bolometer may considerably exceed that of a thermopile under otherwise similar conditions. There is, however, a practical limit to the increase of sensitivity thus obtainable, owing to the heating effect of the current which produces a rise of temperature in the grids proportional to the square of the current. When this becomes excessive, the zero is liable to wander and no further improvement in accuracy of measurement can be gained. The effect is most marked with a "*linear*" bolometer, consisting of a single strip of high resistance, as employed by Langley for measuring the intensity of the absorption lines in the infra-red spectrum. The rise of temperature due to a given current will be many times greater in a single strip than in a grid of many strips

with the same resistance but a much larger surface for dissipating the heat generated.

A *linear thermopile*, in which all the sensitive junctions are arranged in a vertical line, is entirely free from this source of trouble and is generally superior to the bolometer in point of stability of zero. Fig. 11 illustrates the construction of the Moll linear thermopile which is probably the most perfect instrument of this type in respect to constancy of zero as well as quickness of action. There are 20 couples arranged with their hot junctions in a vertical line behind the centre of the slit. The metals employed are the alloys constantan and manganin, both of which possess the property that their resistance does not vary appreciably with temperature. These alloys have the required mechanical properties and can be rolled into very thin strips, which afford excellent receiving surfaces and respond with extreme quickness. One half of each strip consists of constantan and the other half of manganin as indicated in the figure by the shading. The strips are connected in a continuous series, C-M-C-M-C and so on, the cold junctions on either side being soldered to copper studs fixed in insulating blocks at right angles to the plane of the strips. The function of these studs is to keep the cold junctions at a uniform temperature as nearly as possible the same as that of the enclosing case. Great constancy of zero and steadiness of deflection is thus obtained. Thus although the thermo-electric power of a single constantan-manganin couple is only about 40 microvolts per degree, or less than a third of that obtainable with the antimony-bismuth alloys (which are brittle and difficult to work) the superior quickness and constancy and facility of construction of the Con-Mn pile make the latter a more accurate and convenient instrument in practice.

In measuring the intensity of radiation at a distance from the source, where there is no restriction on the area of the beam received, the bolometer has the advantage that it can easily be made of any desired area, and that increase of area permits an increase of sensitivity. This condition cannot be satisfied easily in practice with a thermopile since the multiplication of couples involves a corresponding increase of resistance; but in dealing with *images*, such as spectral lines, of limited area, the thermocouple has the advantage that its sensitive receiving surface can be made to coincide with that of the image to be measured, as in the coronal pile (*Proc. Roy. Soc.*, 1905) for observing the sun's corona. Thus in the extreme case of a point image, such as that of a star, the single couple has a great advantage over the bolometer, which could not easily be made of the required size. By using very small single couples enclosed in a vacuum to reduce external loss of heat, W. W. Coblentz (Lick Observatory, 1915) succeeded in obtaining remarkably accurate measurements of the relative thermal intensities of star images in a large reflecting telescope. The vacuum thermopile recently devised by Moll, with a differential pair of junctions enclosed in a vacuum, would probably be well suited for this kind of work, as the effect of sky radiation would be compensated very accurately.

The *Crookes' radiometer*, with a delicately suspended vane in a vacuum of about 0.02 mm., as improved by Nichols, can be made nearly equal in sensitivity to the radiomicrometer of Boys, but has the disadvantage of requiring the radiation to be introduced through a window, which may in many cases give rise to uncertainty due to selective absorption, in addition to the difficulty of maintaining a constant vacuum.

43. **Absolute Measurement of Radiation.**—The absolute measurement of the constant of radiation σ in the fourth-power

law

$$R = \sigma(T^4 - T_0^4) \quad (15)$$

is required for estimating the quantity of radiation R emitted per second per unit area by a black surface at the absolute temperature T . The law having been verified qualitatively, as previously described, by observing relative values at different temperatures, it suffices for the determination of the constant σ to select one particular temperature of the source, and to observe the intensity of the radiation received at a known distance with a receiver capable of giving the result in absolute measure, such as watts per sq. cm., or gm. cal./cm². sec. It is first necessary that the temperature of the emitter should be uniform and accurately known. For this reason a black body enclosure at 100° C or $T = 373.1$ is commonly selected. The objection to this is that the intensity of the radiation is comparatively feeble and the quantity of heat to be measured inconveniently small as compared with accidental errors. A high temperature such as $T = 1273^\circ$ gets over this difficulty, but such temperatures are not known with sufficient accuracy, and are not easily regulated with the necessary uniformity and constancy. It appears best to select an intermediate temperature, such as the boiling point of sulphur (S.B.P.) at 444.5° C or $T = 817.6^\circ$, which has been determined with great care, and is easily maintained constant.

Fig. 12 shows the essential points of a black body emitter employed for this purpose. The black body consists of a double walled enclosure constructed of sheet iron with brazed or welded joints, which must be absolutely tight to prevent any escape of the vapour. The sulphur is boiled in an iron boiler located in a fume cupboard at a lower level, and the vapour is brought up to the apparatus through a long iron tube to avoid any possibility of superheating. When the sulphur boils, the heavy brown vapour soon makes its appearance in the glass condenser tube at the top of the apparatus. This tube is open at the top, and is exposed without lagging for a height of two or three feet. The boiler flame is regulated to keep the level of the vapour constant about half way up the tube. The condensed liquid flows back through a small tube to the bottom of the boiler, and the apparatus will work for days with hardly any attention. The actual temperature inside the enclosure is observed occasionally with a long platinum thermometer,

FIG. 12.—BLACK BODY EMITTER HEATED BY SULPHUR VAPOUR, FOR MEASURING INTENSITY OF FULL RADIATION FROM A SOURCE AT A TEMPERATURE OF 444.5° C. THE BOILING-POINT OF SULPHUR

and is always a few tenths of a degree lower than that of the vapour, as deduced from the height of the barometer, owing to loss by radiation. The inside of the enclosure is usually blackened in the first instance with platinum black, but soon becomes coated in any case with a protecting film of black oxide of iron, which is generally black enough for the purpose. The emitted beam is defined by an accurately turned aperture in a blackened diaphragm, cooled by a copious circulation of water at or near the atmospheric temperature.

The method of taking an observation consists in exposing the receiver, at a distance d from the diaphragm along the axis of the

aperture, to the full normal beam of radiation, and taking a reading of the heat received. The aperture is then closed by the water-cooled shutter shown in the figure, and a zero reading is taken. The effect of closing the shutter is to substitute for the beam of full radiation at the temperature T of the enclosure, a beam from an exactly equal area of the shutter at the temperature T_0 , which is the same as that of the diaphragm. The observed difference between the two readings gives the value of $\sigma(T^4 - T_0^4)$ as required in the equation, and eliminates any accidental stray radiation, which may affect the zero of the receiver, but is not altered by closing the shutter. If $T = 717.6^\circ$ and $T_0 = 290^\circ$, the correction for T_0^4 is less than 1.6%, so that a defect of 5% in the effective blackness of the diaphragm or shutter would give an error of less than 1 in 1000 in the result for the constant σ , and it is not necessary to know the value of T_0 with great accuracy. The case is quite different, however, in using a black body at 100°C or 373.1°A in the same manner. The correction for T_0 would then amount to nearly 37%, or 23 times larger, and a defect of 5% in the blackness of the shutter might produce an error of nearly 2% in the result. This fact, in addition to the other difficulties above mentioned, has often led to appreciable errors in the use of a black body at 100°C for purposes of reference, and is one of the chief reasons why it is desirable to use a black body at a reasonably high temperature for the determination of the constant σ . Accidental errors of this kind, due to invisible reflections and stray radiation, are most perfectly avoided by completely enclosing the receiver in a water-cooled aluminium casting (aluminium for lightness and high conductivity) at the same temperature as the diaphragm and shutter. The casting has a removable lid permitting easy access for preliminary measurements and adjustments of distance, etc., but this method is so elaborate that it has seldom been attempted. It is also essential to exclude products of combustion such as CO , CO_2 and SO_2 which are highly absorbent for infra-red radiation.

44. Absolute Radiometers.—The measurement of the radiation in absolute units is a more difficult part of the problem than that of securing a good approximation to full radiation at a known temperature. Instruments designed for absolute measurement were first developed for measuring the intensity of solar radiation, and were called *pyrheliometers*. The usual method, as first employed in Pouillet's pyrheliometer, was to receive the solar radiation on a blackened disc of known area and thermal capacity and to observe the rise of temperature produced in a given time. The original apparatus was rather sluggish in action, and the correction for heat-loss somewhat uncertain. The method was improved by Sir G. G. Stokes, J. Violle and A. Crova, by using discs of small thermal capacity and high conductivity, protected from stray radiation, by an enclosure at constant temperature. It is still largely employed for solar radiation, but is much less suitable for weak sources, such as are generally used in laboratory experiments, for which some electrical method of compensation is more convenient and accurate.

Ångström Pyrheliometer.—One of the oldest and best of these compensation methods was first devised by K. Ångström (1890) for measuring solar radiation. His pyrheliometer is illustrated in figs. 13 and 14, and depends on balancing the radiation by electric heating. The front view, fig. 13, shows the pair of blackened strips of very thin manganin, 2 cm. long and 2 mm. wide, one of which is exposed to the radiation to be measured while the other is heated to the same temperature by an electric current. In this case the heat received from the radiation by one strip would evidently be equal to that generated by the current in the other, provided that the two were alike in all respects. Thus if R^1 is the radiant heat absorbed per sq.cm., b the breadth of the strip, C

the current in amperes and r the resistance in ohms per cm., the value of R^1 in watts per sq.cm. is given by the simple relation, $R^1 = C^2 r / b$. The ebonite block carrying the strips and their connecting terminals is fitted in a brass tube the front of which is closed by a cap with two slits corresponding in position with the strips. A swivelling shutter behind the cap permits the screening of either strip. The current is turned on the screened strip by

FIG. 14.—DIAGRAM OF CONNECTIONS OF THE ÅNGSTRÖM PYRHELIOMETER
Showing ammeter circuit, and insulated copper strips for attachment of thermo-junctions

the switch at the back and is adjusted by the rheostat until the galvanometer connected to the thermo-couple indicates equality of temperature by absence of deflection. The thermo-couple consists of a loop of fine constantan wire, the ends of which are connected to strips of copper foil attached to the backs of manganin strips as indicated in the diagram of connections (fig. 14). Each copper strip is attached as closely as possible to its manganin strip, but is insulated from it by thin silk paper and shellac. The copper strips provide a reliable attachment for the two junctions

of the couple and help to equalize the temperature of the strip. The object of balancing one strip against the other is to make the reading as sensitive as possible, and to eliminate any disturbances depending on changes of temperature of the case, which would affect both strips equally. To eliminate small differences between the strips, the reading is repeated with the second strip screened and heated by the current while the first is exposed to radiation. The mean of the results is free from errors due to want of symmetry, provided that such errors are small. In this balance method of observation the result is practically independent of the accuracy of the galvanometer, but an error of 1% in the current C as measured by the ammeter would give an error of 2% in the result, since it depends on C^2 . The result also depends on the breadth of the strip b and on its resistance r per cm., both of which are difficult to measure accurately, more especially when the strip is blackened with smoke, which makes the edge somewhat ill defined. In any case the value of R , representing the heat actually absorbed, will depend on the coefficient of absorption of the smoke film, which is generally taken as 98% but may vary somewhat for different wave-lengths and different smoke films.

Kurlbaum's bolometric method can be applied to any sensitive bolometer of suitable construction, and avoids some of the difficulties of measurement inherent in Ångström's method, but introduces others which make it less convenient for solar radiation. The method consists in observing the deflection D of the galvanometer when the bolometer is exposed to the radiation to be measured and is traversed by the small current c usually employed. The grid is then screened from radiation, and the current is increased to a larger value C such that the galvanometer gives the same deflection D due to the additional heat generated by the current in the grid. The intensity of the radiation R^1 in watts per sq.cm. is given in terms of the resistance r per sq.cm. of the grid by the formula, $R^1 = r(C^2 - c^2)C/c$. The difficulty of measuring the width of the strips may be avoided by using a pair of similar grids, adjusted in such a way that the strips of the second are behind the spaces between the strips of the first. The whole area of the grid may thus be utilized, and r is the whole resistance in ohms divided by the area in sq.cm. The factor C/c is required in the formula to allow for the fact that the deflection D of the galvanometer for a given increase of resistance of the grid is directly proportional to the current. The accuracy of measurement of the currents C and c is rather more important than in Ångström's method, but the bolometric method avoids the measurement of b and makes that of r very easy. On the other hand it is necessary to balance the bolometer against manganin resistances which are not appreciably affected by the current C . This makes it impossible to compensate for changes in the temperature of the surroundings in the usual

FIG. 13.—ÅNGSTRÖM PYRHELIOMETER, SHOWING FRONT VIEW OF STRIPS

Radiation received by one strip is measured by heating the other with an electric current to same temperature as indicated by a thermo-couple

way (by balancing the receiving grid against a precisely similar grid) since both would be equally heated by the current C . Kurlbaum employed a black body at 100°C as source, and the actual rise of temperature of the grid due to the incident radiation with the small current c was only about a tenth of 1°C . The rise of temperature due to increasing the current from c to C would be less than this in the ratio c/C . The successive observations of

FIG. 15.—BLACK BODY RECEIVER OF RADIO BALANCE

The radiation to be measured is received in a blackened copper cup giving practically complete absorption, and is balanced by heat absorbed in a Peltier thermo-junction

radiation and current-heating would be unequally affected by any change in the surrounding conditions, and the difficulties of the method make it unsuitable for employment except in the laboratory with weak sources under very steady conditions.

Employing this method Kurlbaum (*Wied. Ann.*, 1898) found the value $\sigma = 5.32 \times 10^{-5}$ ergs per sq.cm. per sec., or 5.32×10^{-12} watts per sq.cm., but this rested on a somewhat doubtful estimate of the absorption coefficient of the bolometer employed, and was raised at a later date (1912) from 5.32 to 5.45. Paschen and Gerlach (*Ann. Phys.* 1912) employed a modification of Ångström's method, but with a single strip (in place of a pair of strips) of measured area and resistance, which was alternately exposed to the radiation to be measured and heated by a measured electric current. The rise of temperature of the strip was indicated, and adjusted approximately to the same value in either case, by observing the deflection of a galvanometer connected to a linear pile fixed in position close behind the strip but not in contact with it. The method is inferior in some respects to Ångström's, especially in the absence of a balancing strip, and in its dependence on the accurate observation of successive deflections. On the other hand the single strip employed by Paschen and Gerlach is easier to make than the compound strip employed by Ångström, and the measurement of its breadth b and resistance r per cm. should be more accurate. They used a linear thermopile equal in length to the strip, and deduced the value of r per cm. from measurements of the whole length and resistance, whereas Ångström measured r by observing the potential difference between a pair of needle-point potential terminals fixed at a distance of 1 cm. apart, and brought into contact with the central portion of the strip while a measured current was passing through it. This was a delicate operation, but was necessitated by the fact that he used a single couple at the centre of the strip, and that there might be some uncertainty about the resistance of the contacts at the end of the strip, since the compound strip could not be soldered satisfactorily to the terminal plates. Gerlach's later measurements (1916), in which corrections were applied for the imperfect blackness of platinum black and for atmospheric absorption, gave a final value $\sigma = 5.80 \times 10^{-12}$ watt per sq.cm. which, though appreciably lower than his original uncorrected value, 5.85, was still nearly 7% higher than Kurlbaum's final value 5.45 by the bolometric method. It was suggested that these discrepancies might be due to inequalities of temperature due to loss of heat by conduction from the ends of the strip. Coblenz and Emerson (*Bur. Stds. Bull.*, 1916) endeavoured to avoid this difficulty by attaching potential terminals to the strip at a short distance from the ends. These terminals tend to cool the strip locally, but they estimate the cooling effect as only about 0.3%. Comparing a number of different receivers of this type they found variations amounting in some cases to 2%, with a probable order of 1% for the accuracy of the mean. They gave a final value 5.73 for the constant after ap-

plying corrections for imperfect blackness and atmospheric absorption.

The Radiobalance, employed by Callendar (*Proc. Phys. Soc.* 1910), was the first serious attempt to eliminate uncertain coefficients of absorption (which depend on the wave-length of the radiation as well as on the blackness and conductivity of the film) by employing a black-body receiver, designed to give complete absorption with an error of less than 0.1%. The construction of this receiver which can be used in any position, is illustrated in the fig. 15, on an enlarged scale. The radiation to be measured is admitted through an optically worked aperture of 2 mm. dia. (which is comparatively easy to measure with the requisite degree of accuracy) and falls on the bottom of a small copper cup, where it is directly compensated by the absorption of heat due to the Peltier effect in a thermojunction formed between the cup and a constantan wire through which a suitable current is passed. Any change of temperature of the cup is indicated by a sensitive galvanometer, connected to a thermopile in which the cup is mounted as shown in fig. 16. The junctions of the pile are insulated from the cup by thin silk paper and paraffin wax, which is non-hygroscopic, and are bound firmly round the cup with a lapping of fine silk. The pile wires are iron and constantan each 0.2 mm. dia. and are sufficiently stiff to hold the cup securely in place. The cold junctions of the pile are similarly fixed to a copper cylinder screwed to the base of the copper box 5 mm. thick enclosing the sensitive parts of the apparatus at a uniform temperature, which is indicated by a delicate mercury thermometer with its bulb inserted between the two piles. Since it is always desirable to take observations by a balance method (most especially in measuring strong sources of radiation, such as 1 cal. per sq.cm. per min., or 0.07 watt per sq.cm., which would give unbalanced deflections of the galvanometer of the order of 7,000 mm.) the cup exposed to radiation is balanced against a similarly mounted cup, as indicated in the diagram of connections fig. 17, the piles in which the cups are mounted being connected in opposition in the galvanometer circuit. This method gives very perfect elimination of external disturbances owing to the small size and high conductivity of the copper box in which the two piles are enclosed.

FIG. 16.—CUP AND PILE OF RADIO-BALANCE, SHOWING MOUNTING OF CUP IN SENSITIVE THERMOPILE WITH 12 JUNCTIONS INSIDE COPPER BOX

aperture of 2 mm. dia. the current required to compensate radiation of intensity 0.07 watt per sq.cm., which is near the mean for sunshine, is about 200 milliamps. with a single couple. In actual practice the same current C is passed through the Peltier junctions of both cups so that the exposed cup is cooled while the screened cup is heated. This doubles the effect and requires a current of 100 milliamps. only, in the case above given, and makes it possible to measure strong sources up to 0.4 watt per sq.cm., without changing the 2 mm. aperture.

In taking readings by this method, one cup is exposed to radiation while the other is screened, and the current is adjusted to reduce the deflection of the galvanometer to zero. After reading

The advantage of using the Peltier effect for the absolute measurement of radiation, in place of the more familiar Joule effect employed in other instruments such as the Ångström pyrheliometer, is that heat reception can be directly compensated by heat absorption, and that the heat absorbed is proportional to the current C (instead of to C^2) and changes sign when the current is reversed. The value of the Peltier coefficient P for a single copper-constantan junction as here employed is approximately 12 millivolts, which when multiplied by the current C in amperes gives the heat absorption PC in milliwatts. Thus with an

the current, the radiation is switched over to the other cup (by moving a shutter close in front of the aperture and behind the tin plate screen in fig. 16) and the current is simultaneously reversed without altering its value. This procedure has the effect of exactly eliminating any small heating effect in the wires conveying the current to the cups, and gives the simple formula $R' = 2PC/a$, for the intensity R' of the radiation received in terms of the aperture a in sq. cm. If the radiation is variable, as is usually the case with sunshine even on the clearest day, it is preferable to keep the current constant and to observe the small residual deflections of the galvanometer, which are readily translated into milliamps. by observing the deflection produced by reversing a small current when both cups are screened. If the piles are not accurately balanced, or if the areas of the apertures are not exactly equal, the appropriate value of the balancing current will be different for the two cups. Any small differences of this kind may be treated in the same way by observing galvanometer deflections, but should not exceed a small fraction of 1%.

The value of the coefficient P is most easily determined by observing the thermoelectric power p of a junction made of the same wires, and multiplying by the absolute temperature T . Both factors in the product Tp increase with temperature, so that it is necessary to know the temperature to 0.2°C in order to secure an order of accuracy of 0.1% in R' , since the temperature coefficient of P is usually in the neighbourhood of 0.5% per 1°C . A more direct method is to balance the Peltier effect in each cup against the heating effect in a resistance coil fitting the cup. This method affords the most simple and accurate verification of the thermodynamic theory, and measures the effect under working conditions for the actual couples employed. To find the value of σ by observing the radiation emitted from a black body such as that illustrated in fig. 12, with a water cooled aperture of radius b , it is necessary to adjust the aperture a of the receiver to be coaxial with that of the emitter and to measure the distance d between their planes. The normal intensity R' as measured by the receiver is given in terms of the black body intensity R in formula (15) by the simple relation $R' = Rb^2/(d^2 + b^2)$, which may be found in most textbooks of geometrical optics.

Observations taken with radiobalance D (one of the instruments described in *Proc. Phys. Soc.* 1910) in conjunction with the black body illustrated in fig. 12, by N. L. Jones gave a mean result 0.5690×10^{-12} watt per sq. cm. The observations were taken at night under favourable conditions, but no correction was applied for atmospheric absorption, as the distance (29 to 33 cm.) was not varied sufficiently. Later observations made by Callendar using a black body at 100°C with the same instrument, in which the distance d was varied from 6 to 56 cm. under similar conditions, gave a result 5.752 when corrected for atmospheric absorption. The Peltier couple in this instrument was tested by the thermoelectric method using samples of the same wires, iron and constantan respectively. Another balance (E), with a copper-constantan couple, tested by both methods with consistent results, and corrected for atmospheric absorption in the same way, gave a slightly higher result, 5.766. The differences between observations taken on different days averaged about 0.2% and appeared to depend mainly on variations of atmospheric absorption, the correction for which doubled the time and labour of taking observations. The percentage absorbed varies to some extent with the quality of the radiation as determined by the temperature of the emitter as well as the state of the atmosphere, and is not simply proportional to the distance traversed as commonly assumed. The observations with the black body at 444.5°C , when corrected by reference to hygrometric records, using the coefficient found at 100°C , were raised from a mean value 5.690 to 5.804, which suggests that the absorption correction should be smaller for radiation at 444.5°C than at 100°C . The mere presence of an observer radiating heat and exhaling variable quantities of CO_2 is a source of uncertainty in absolute measurements. Apart from atmospheric absorption, the instrument appeared to be capable of an order of accuracy of at least 0.1%. It was accordingly decided to enclose the receiver in a water-cooled metal casting from which absorbing gases could be excluded. Unfortunately at

this stage the work was interrupted by the World War, and no favourable opportunity has since occurred for making the final corrections for absorption. It appears, however, that the result would probably be intermediate between those of Gerlach and Coblentz by the Ångström method. A number of other highly ingenious methods have been employed for the absolute determination of this important constant, but have generally been inferior

to the electric methods in quickness and sensitivity, and do not promise so high a degree of accuracy. Some experienced observers have found values as high as 6.5, but there are many most insidious sources of error in these difficult experiments.

FIG. 17.—DIAGRAM OF CONNECTIONS FOR RADIOBALANCE

Both cups, with circuit of Peltier junction separate from that of piles and galvanometer, are shown

to the electric methods in quickness and sensitivity, and do not promise so high a degree of accuracy. Some experienced observers have found values as high as 6.5, but there are many most insidious sources of error in these difficult experiments.

45. Wien's Displacement Law.—Assuming that the fourth power law gives the quantity of full radiation at any temperature it remains to determine how the quality of the radiation varies with the temperature, since as we have seen both quantity and quality are determinate. This question may be regarded as consisting of two parts. (1) How is the wave-length or frequency of full or "black" radiation changed when its temperature is altered? (2) What is the form of the curve expressing the distribution of energy between the various wave-lengths in the spectrum of full radiation, or what is the distribution of heat in the spectrum? The researches of Tyndall, Draper, Langley and other investigators had shown that while the energy of radiation of each frequency increased with rise of temperature, the maximum of intensity was shifted or displaced along the spectrum in the direction of shorter wave-lengths or higher frequencies. W. Wien (*Ann. Phys.*, 1898), applying Doppler's principle to the adiabatic compression of radiation in a perfectly reflecting enclosure, deduced that the wave-length of each constituent of the radiation should be shortened in proportion to the rise of temperature produced by the compression, in such a manner that the product λT of the wave-length and the absolute temperature should remain constant. According to this relation, which is known as *Wien's displacement law*, the frequency corresponding to the maximum ordinate of the energy curve of the normal spectrum of full radiation should vary directly (or the wave-length inversely) as the absolute temperature, a result previously obtained by H. F. Weber (1888). Paschen, Lummer and Pringsheim verified this relation by observing with a bolometer the intensity at different points in the spectrum produced by a fluorite prism. The intensities were corrected and reduced to a wave-length scale with the aid of Paschen's results on the dispersion formula of fluorite (*Wied. Ann.*, 1894). The curves in fig. 18 illustrate curves obtained by Lummer and Pringsheim (*Ber. deut. phys. Ges.*, 1899) at three different temperatures, namely $1,377^\circ$, $1,087^\circ$ and 836° absolute, plotted on a wave-length base with a scale of microns μ or millionths of a metre. The wave-lengths Oa , Ob , Oc , corresponding to the maximum ordinates of each curve, vary inversely as the absolute temperatures given. The constant value of the product λT at the maximum point was found to be 2,920. Thus for a temperature of $1,000^\circ\text{A}$ the maximum is at wave-length 2.92μ ; at $2,000^\circ$ the maximum is at 1.46μ .

FIG. 18.—DISTRIBUTION OF ENERGY IN THE SPECTRUM OF A BLACK BODY

46. Distribution of Energy in the Spectrum.—Assuming Wien's displacement law, it follows that the form of the curve representing the distribution of energy in the spectrum of full radiation should be the same for different temperatures with the maximum displaced in proportion to the absolute temperature, and with the total area increased in proportion to the fourth power

of the absolute temperature. Observations taken with a bolometer along the length of a normal or wave-length spectrum, would give the form of the curve plotted on a wave-length base. The height of the ordinate at each point would represent the energy included between given limits of wave-length, depending on the width of the bolometer strip and the slit. Supposing that the bolometer strip had a width corresponding to 0.01μ , and were placed at 1.0μ in the spectrum of radiation at $2,000^\circ\text{A}$, it would receive the energy corresponding to wave-lengths between 1.00 and 1.01μ . At a temperature of $1,000^\circ\text{A}$ the corresponding part of the energy, by Wien's displacement law, would lie between the limits 2.00 and 2.02μ , and the total energy between these limits would be 16 times smaller. But the bolometer strip placed at 2.0μ would now receive only half of the energy, or the energy in a band 0.01μ wide, and the deflection would be 32 times less. Corresponding ordinates of the curves at different temperatures will therefore vary as the fifth power of the temperature, when the curves are plotted on a wave-length base. The maximum ordinates in the curves already given are found to vary as the fifth powers of the corresponding temperatures.

The equation representing the distribution of energy on a wave-length base must be of the form

$$E = C\lambda^{-5} F(\lambda T) = CT^5(\lambda T)^{-5} F(\lambda T) \quad (16)$$

where $F(\lambda T)$ represents some function of the product of the wave-length and temperature, which remains constant for corresponding wave-lengths when T is changed. If the curves were plotted on a frequency base, owing to the change of scale, the maximum ordinates would vary as the cube of the temperature instead of the fifth power, but the form of the function F would remain unaltered. Reasoning on the analogy of the distribution of velocities among the particles of a gas on the kinetic theory, which is a very similar problem, Wien was led to assume that the function F should be of the form $e^{-c/\lambda T}$, where e is the base of Napierian logarithms, and c is a constant having the value 14,600 if the wave-length is measured in microns μ . This expression was found by Paschen to give a very good approximation to the form of the curve obtained experimentally for those portions of the visible and infra-red spectrum where observations could be most accurately made. The formula was tested in two ways: (1) by plotting the curves of distribution of energy in the spectrum for constant temperatures as illustrated in fig. 19; (2) by plotting the energy corresponding to a given wave-length as a function of the temperature. Both methods gave very good agreement with Wien's formula for values of the product λT not much exceeding 3,000.

A method of isolating rays of great wave-length by successive reflection was devised by H. Rubens and E. F. Nichols (*Wied. Ann.*, 1897). They found that quartz and fluorite possessed the property of selective reflection for rays of wave-length 8.8μ and 24μ to 32μ respectively, so that after four to six reflections these rays could be isolated from a source at any temperature in a state of considerable purity. The residual impurity at any stage could be estimated by interposing a thin plate of quartz or fluorite which completely reflected or absorbed the residual rays, but allowed the impurity to pass. H. Beckmann, under the direction of Rubens, investigated the variation with temperature of the residual rays reflected from fluorite employing sources from -80° to 600°C , and found the results could not be represented by Wien's formula unless the constant c were taken as 26,000 in place of 14,600. In their first series of observations extending to 6μ O. R. Lummer and E. Pringsheim (*Deut. phys. Ges.*, 1899) found systematic deviations indicating an increase in the value of the constant c for long waves and high temperatures. In a theoretical discussion of the subject, Lord Rayleigh (*Phil. Mag.*, 1900) pointed out that Wien's law would lead to a limiting value $C\lambda^{-5}$, of the radiation corresponding to any particular wave-length when the temperature increased to infinity, whereas according to his view the radiation of great wave-length should ultimately increase in direct proportion to the temperature. Lummer and Pringsheim (*Deut. phys. Ges.*, 1900) extended the range of their observations to 18μ by employing a prism of sylvine in place of

fluorite. They found deviations from Wien's formula increasing to nearly 50% at 18μ , where, however, the observations were very difficult on account of the smallness of the energy to be measured. Rubens and F. Kurlbaum (*Ann. Phys.*, 1901) extended the residual reflection method to a temperature range from -190° to $1,500^\circ\text{C}$, and employed the rays reflected from quartz 8.8μ , and rocksalt 51μ , in addition to those from fluorite.

It appeared from these researches that the rays of great wave-length from a source at a high temperature tended to vary in the limit directly as the absolute temperature of the source, as suggested by Lord Rayleigh, and could not be represented by Wien's formula with any value of the constant c . The formula now

FIG. 19.—DISTRIBUTION OF ENERGY IN THE SPECTRUM OF FULL RADIATION AT $2,000^\circ\text{A}$, ACCORDING TO FORMULAE OF PLANCK AND WIEN

generally accepted is that proposed by Max Planck (*Ann. Phys.*, 1901) namely,

$$E = C\lambda^{-5} (e^{c/\lambda T} - 1)^{-1}, \quad (17)$$

which agrees with Wien's formula when T is small, where Wien's formula is known to be satisfactory, but approaches the limiting form $E = C\lambda^{-4} T/c$, when T is large, thus satisfying the condition proposed by Lord Rayleigh. The theoretical interpretation of this formula is discussed in the article RADIATION. The most recent value of the constant c in Planck's formula is 14,300, as given by Warburg. In order to compare Planck's formula graphically with Wien's, the distribution curves corresponding to both formulae are plotted in fig. 19 for a temperature of 2000°A , with a scale of wave-length in microns μ .

The curves in fig. 20 illustrate the difference between the two formulae for the variation of the intensity of radiation with temperature for a fixed wave-length 30μ which is five times as long as the limit 6μ of the curves in fig. 20. But at $2,000^\circ\text{A}$ the energy to be measured at 30μ is about ten thousand times less than at the maximum of the curve in fig. 20. Assuming Wien's displacement law, the curves may be applied to find the energy for any other wave-length or temperature, by simply altering the wave-length scale in inverse ratio to the temperature, or vice versa. Thus to find the distribution curve for $1,000^\circ\text{A}$, it is only necessary to multiply all the numbers in the wave-length scale of fig. 19 by 2; or to find the variation curve for wave-length 60μ the numbers on the temperature scale of fig. 20 should be divided by 2. The ordinate scales must be increased in proportion to the fifth power of the temperature, or inversely as the fifth power of the wave-length respectively in figs. 19 and 20 if comparative results are required for different temperatures or wave-lengths.

FIG. 20.—VARIATION OF ENERGY OF RADIATION CORRESPONDING TO WAVE-LENGTH 30μ WITH TEMPERATURE OF SOURCE

SPECIFIC HEAT AT LOW TEMPERATURES

47. The early experiments of Sir J. Dewar, Sir W. A. Tilden and others had shown that solids at low temperatures deviated from Dulong and Petit's law of the constancy of atomic heat in the same way as carbon, boron and silicon, at ordinary temperatures, but they failed to show the full extent of the deviation, or to indicate a probable explanation. A. Einstein suggested (*Ann. Phys.*, 1907) that the atom of a solid might be regarded as an electric resonator with three degrees of freedom possessing a particular frequency, independent of the temperature and capable of responding to the same frequency of radiation. Adopting Planck's theory and radiation formula, he showed that the specific heat at constant volume should approach the limit $3R = 5.94$ calories per gram-atom at high temperatures, as required by Dulong and Petit's law, but that the variation at low temperatures

should be given by the expression

$$s = 3R\epsilon^2 e^z (e^z - 1)^2 = 3Rf(z) \quad (18)$$

where $z = 3\nu T / c\lambda T$, as in Planck's formula. The symbol ν denotes the natural frequency of the atoms, and λ the corresponding wave-length in cm. such that $\nu\lambda = 3 \times 10^{10}$, the velocity of light. Taking H. F. Weber's observations on the variation of the specific heat of the diamond, extending from $T = 222^\circ$ to $1,258^\circ$ A. Einstein showed that they agreed qualitatively with this formula, if we could assume the diamond atoms to possess a single frequency corresponding to the wave-length 11 microns. Taking the substances, CaF₂, NaCl, KCl, CaCO₃ and SiO₂, for which the optical frequencies in the infra-red were known, he showed that the frequencies agreed in order of magnitude with those required by his formula, but that the observed wave-lengths were somewhat shorter than those calculated from the specific heats. This could be attributed to the fact that most of the substances showed more than one frequency, and that the frequencies were not strictly monochromatic, as indicated by the width of the corresponding absorption bands. In any case there were other effects, such as work of expansion, included in the specific heats as ordinarily measured, and it might be doubted whether the optical frequencies corresponded exactly with the thermal vibrations of the atoms.

Experiments on Solids.—An important series of experimental measurements, extending down to the temperature of liquid hydrogen, was made by W. Nernst, F. A. Lindemann and their collaborators (*Sitz. Akad., Berlin*, 1911), on a number of metals and other solids, including those for which the optical frequencies were known. They found, as already indicated, that Einstein's formula gave too low values for the specific heats at low temperatures, if the optical frequencies were assumed in calculating the value of $f(z)$, and that much better agreement could be obtained by taking the mean of $f(z)$ for the optical frequency, and a similar term, $f(z/2)$ at half the optical frequency:—

$$s = 3R[f(z) + f(z/2)]/2 = 3Rf''(z) \quad (19)$$

The same function, $f''(z)$, of z was assumed to apply to other substances, such as the metals, but the appropriate values of z were selected to fit the observations on the specific heats. Some substances, such as SiO₂ (in the forms of quartz and quartz-glass) and benzene, C₆H₆, which gave a different type of curve, were represented by formulae with two or three different values of z , each value of $f''(z)$ being multiplied by a fractional coefficient representing the proportion in which the corresponding molecule was supposed to be present. But such cases could not be regarded as a verification of the theory, because it would obviously be possible to represent almost any type of variation in this way.

Einstein objected that even the simplest of these formulae, namely (19), was too empirical to be satisfactory from a theoretical standpoint; that a cubical crystal, such as KCl, or NaCl, could not have two different frequencies; and that there was no evidence in either case of an optical frequency with half the experimental value, since, according to Rubens, the crystals became again transparent before this frequency was reached, and had a value of the refractive index which was nearly normal. He also indicated two other objections to the *quantum theory* on which Planck's formula was based. (1) According to the quantum theory it did not follow, as required by the classical mechanics, that the oscillator with three degrees of freedom would have three times the energy of a linear oscillator. (2) It was very difficult to conceive the distribution of energy among the oscillators at low temperatures required by the theory. Thus for the diamond at $T = 73^\circ$ A only one molecule in 100 millions would possess a single quantum of energy, all the rest would be absolutely quiescent. It was physically impossible to conceive such a distribution of energy, which moreover would make the thermal conductivity of the diamond at such temperatures entirely negligible, whereas, according to Eucken, it was nearly as great as that of copper at ordinary temperatures. For these reasons Einstein preferred to rely mainly on the expression for the energy of an electric oscillator in equilibrium with radiation as deduced from Maxwell's equations, and to regard Planck's formula for the dis-

tribution of energy in full radiation simply as representing the results of experiment.

Debye's Theory of Specific Heat of Solids.—The theory now most commonly accepted is that of P. Debye (*Ann. Phys.*, 1912), who attributes the heat energy to mechanical or acoustic vibrations of the solid with all possible frequencies up to a certain limit ν_m . According to a theorem attributed to the late Lord Rayleigh (*Sound*, i., 1877) the number of possible degrees of freedom of a system of N discontinuous mass-points will be $3N$. According to another theorem by the same author (*Phil. Mag.*, 1900), the number of possible frequencies in a given volume of a *continuous* medium between the limits ν and $\nu + d\nu$ may be represented by $C'\nu^2 d\nu$, where C' is a constant depending on the volume and the velocity of propagation. The total number of possible frequencies from 0 up to a limit ν_m is $C'\nu_m^3/3$. If we equate this to $3N$, we find $C' = 9N/\nu_m^3$. Adopting Planck's expression for the energy of an electric oscillator with one degree of freedom as applying to each possible frequency of the N atoms in a gram-atom, we obtain the energy $(RT/N)z/(e^z - 1)$ for each frequency. Multiplying this by the number of frequencies between ν and $\nu + d\nu$, namely $(9N/\nu_m^3)\nu^2 d\nu$, and integrating from 0 to ν_m , we obtain the energy of a gram-atom at T , from which the specific heat at constant volume is obtained by differentiation with regard to T . Unfortunately the integral cannot be expressed in finite terms and is too complicated to reproduce here. It is evident, however, that it will be a function of z_m , or $\beta\nu_m/T$, or T_m/T , where $T_m = \beta\nu_m$.

Thus the *form* of the curve representing the variation of the specific heat (which depends on a single parameter T_m or ν_m) is the same for all substances on Debye's theory, if the temperature scale is altered for each in proportion to ν_m . This point has been very carefully tested by E. H. Griffiths and E. Griffiths (*Phil. Trans.*, A, 1914) for the metals Al, Ag, Cd, Cu, Fe, Na, Pb, Zn. Their results indicate qualitative agreement with the theory, but show characteristic differences, greatly exceeding the limit of experimental error, which may possibly be attributed to other effects not included in the simple theory. Thus the curve for Fe differs from that for Cu by nearly 20% between corresponding temperatures, which may be attributed to the magnetic properties of Fe. The curve for Na shows a rapid rise towards the melting point, reaching an excess of 25% above $3R$, followed by a diminution of specific heat for the liquid, as in the case of water and mercury. Many simple compounds, such as NaCl, show curves of a very similar type to the metals, which has been used as an argument that the specific heat must be attributed entirely to the atoms, and that the free electrons supposed to exist in metals cannot make any appreciable contribution. Thus if there were two free electrons per atom, as required by some theories, the electrons alone would account for the whole specific heat according to the kinetic theory at ordinary temperatures; and it would be necessary to suppose that the number of free electrons diminished to zero at low temperatures, which would make it difficult to account for the enormous increase in electric conductivity of pure metals demonstrated by Kamerlingh Onnes in the neighbourhood of the absolute zero. There can be little doubt that the properties of any substance are intimately related to the natural frequencies of the molecules, but the form of the relation cannot be predicted with certainty; and the quantitative measurements are not yet sufficiently exact to distinguish between many possible hypotheses.

Specific Heat of a Gas.—The experiments of A. Eucken (*Sitz. Akad., Berlin*, 1912) on the specific heat of hydrogen at low temperatures were very instructive in this connection. The gas was electrically heated at various temperatures in a thin steel vessel under considerable pressure at constant volume. The specific heat was found to diminish from nearly $5R/2$ at ordinary temperatures to nearly $3R/2$ at $T = 60^\circ$, after which it remained practically constant down to $T = 35^\circ$. The experiments were undoubtedly of considerable difficulty, but there seems no reason to doubt their substantial accuracy.

Eucken's results have recently been confirmed with remarkable precision by J. H. Brinkworth (*Proc. Roy. Soc. [A]* 1925) using an entirely independent method of experiment. He observed the

cooling effect in adiabatic expansion with a compensated platinum thermometer at various temperatures between 20°C and -183°C , and deduced the corresponding values of the ratio of the specific heats at constant pressure and at constant volume. The actual specific heats at any temperature could be deduced with certainty from these observations. This method is unaffected by the thermal capacity of the containing vessel, whereas in Eucken's

FIG. 21.—MOLECULAR SPECIFIC HEAT OF HYDROGEN AT CONSTANT VOLUME

The curve shows change from $3R/2$ (the value appropriate to a monatomic gas like helium) at 50°A to the value $5R/2$ at 300°A . The latter is the appropriate value for a diatomic molecule, such as nitrogen, the specific heat of which remains nearly constant over this range

method the thermal capacity of the vessel must be known with considerable accuracy. Brinkworth also showed that the heat-loss could be most satisfactorily eliminated by using vessels of different sizes. Assuming that the variation of the specific heat was due to the response of some particular frequency of the molecule to the same frequency in natural radiation at each temperature, he states that Callendar's radiation formula fits the observations better than Planck's but that satisfactory agreement cannot be obtained by assuming a single frequency. Reiche's calculations do not seem to improve the agreement.

It would appear that the specific heat of the most perfect gas may vary quite independently of the kinetic energy of its molecules, and that the Boltzmann dumbbell model of a diatomic molecule, with five equal degrees of freedom, cannot longer be maintained. The form of the curve representing the variation of the specific heat between 50° and 300°A as shown in fig. 21, is similar to that found for the diamond at low temperatures, and suggests that the variation is related to some natural frequency of the hydrogen molecule according to Einstein's theory but the exact nature of the relation remains at present obscure.

HEATH, BENJAMIN (1704–1766), English classical scholar and bibliophile, was born at Exeter on April 20, 1704, and died on Sept. 13, 1766. He was the son of a wealthy merchant, and was thus able to devote himself mainly to travel and book-collecting. As a classical scholar he made his reputation by his critical and metrical notes on the Greek tragedians. He also left

ms. notes on Burmann's and Martyn's editions of Virgil, on Euripides, Catullus, Tibullus and the greater part of Hesiod. His *Revisal of Shakespear's Text* (1765) was an answer to the "insolent dogmatism" of Bishop Warburton. Two of his sons were Benjamin, headmaster of Harrow, and George, headmaster of Eton. His collection of rare classical works formed the nucleus of his son Benjamin's famous library (Bibliotheca Heathiana).

An account of the Heath family will be found in Sir W. R. Drake's *Heathiana* (1882).

HEATH, NICHOLAS (c. 1501–78), archbishop of York and lord chancellor, was born in London. He was educated at Oxford and at Christ's college, Cambridge, and after minor preferments he was appointed archdeacon of Stafford in 1534. He then accompanied Edward Fox (q.v.), bishop of Hereford, on his mission to promote a theological and political understanding with the Lutheran princes of Germany. In 1539, he was made bishop of Rochester, and in 1543 succeeded Latimer at Worcester. He accepted the earlier reforms of Edward VI., and the first book of common prayer after it had been modified by the House of Lords in a Catholic direction. His definite breach with the Reformation occurred on the question of the Ordinal drawn up in 1550. Heath refused to accept it, was imprisoned, and in 1551 deprived of his bishopric. On Mary's accession he was restored, made president of the council of the Marches and Wales, and in 1555 was promoted to the archbishopric of York. After the death of Gardiner he was appointed lord chancellor. On Mary's death Heath as chancellor at once proclaimed Elizabeth. Although the queen did not renew his commission as lord chancellor, he continued to sit in the privy council for two months until the government completed the breach with the Catholic Church; and as late as April 1559 he assisted in the arrangement of the Westminster Conference. He refused to crown Elizabeth because she would not have the coronation service accompanied with the elevation of the Host and resisted her acts of supremacy and uniformity, although he had acquiesced in the acts of 1534 and 1549. He was deprived of his archbishopric in 1559, but he remained loyal to Elizabeth; and after a temporary confinement he passed the remaining 19 years of his life in peace, dying at Chobham, Surrey at the end of 1578.

HEATH, WILLIAM (1737–1814), American soldier, was born in Roxbury, Mass., on March 2, 1737 (old style). He was brought up as a farmer but had a passion for military exercises. In 1765 he entered the Ancient and Honourable Artillery company of Boston, of which he became commander in 1770. In the same year he wrote to the *Boston Gazette* letters signed "A Military Countryman," urging the necessity of military training. He was a member of the Massachusetts general court from 1770 to 1774, of the provincial committee of safety, and from 1774–1775 of the provincial congress. He was commissioned a provincial brigadier-general in 1774, directed the pursuit of the British from Concord (April 19, 1775), was promoted to be provincial major-general on June 20, 1775, and two days later was commissioned fourth brigadier-general in the Continental army. He became major-general in 1776, and was in active service around New York until early the next year. In Jan. 1777 he attempted to take Ft. Independence, near Spuyten Duyvil, then garrisoned by about 2,000 Hessians, but at the first sally of the garrison his troops became panic-stricken and a few days later he withdrew. Washington reprimanded him. Throughout the war, however, Heath was very efficient in muster service and in the barracks. In May 1779 he was appointed a commissioner of the board of War. He was placed in command of the troops on the east side of the Hudson in June 1779, and of other troops and posts on the Hudson in November of the same year. In July 1780, he met the French allies under Rochambeau on their arrival in Rhode Island; in October of the same year he succeeded Arnold in command of West Point and its dependencies; and in Aug. 1781, when Washington went south to meet Cornwallis, Heath was left in command

of the army of the Hudson to watch Clinton. After the war he retired to his farm at Roxbury, was a member of the State house of representatives in 1788, of the Massachusetts convention which ratified the Federal Constitution in the same year, and of the governor's council in 1789-90. He was a State senator 1791-93. He died at Roxbury Jan. 24, 1814, the last of the major-generals of the Revolutionary War.

See *Memoirs of Major-General Heath, containing Anecdotes, Details of Skirmishes, Battles, and other Military Events during the American War, written by Himself* (Boston, 1798; frequently reprinted), particularly valuable for the descriptions of Lexington and Bunker Hill, of the fighting around New York, of the controversies with Burgoyne and his officers during their stay in Boston, and of relations with Rochambeau; and his correspondence, *The Heath Papers*, vols. iv.-v., seventh series, *Massachusetts Historical Society Collections* (Boston, 1904-05).

HEATH, the English form of a name given in most Teutonic dialects to the common ling or heather (*Calluna vulgaris*), but now applied to all species of *Erica*, an extensive genus of monopetalous plants, belonging to the family Ericaceae. The heaths are evergreen shrubs, with small narrow leaves, in whorls usually set rather thickly on the shoots; the persistent flowers have 4 sepals, and a 4-cleft campanulate or tubular corolla, in many species more or less ventricose or inflated; the dry capsule is 4-celled, and opens, in the true *Ericae*, in 4 segments, to the middle of which the partitions adhere, though in the ling the valves separate at the dissepi-ments. The plants are mostly of low growth, but several African kinds reach the size of large bushes, and a common South European species, *E. arborea*, occasionally attains almost the aspect and dimensions of a tree.

One of the best known and most interesting of the family is the common heath, heather or ling, *Calluna vulgaris*, placed by most botanists in a separate genus on account of the peculiar dehiscence of the fruit, and from the coloured calyx, which extends beyond the corolla, having a whorl of sepal-like bracts beneath. This shrub derives some economic importance from its forming the chief vegetation on many of those extensive wastes that occupy so large a portion of the more sterile lands of northern and western Europe, the usually desolate appearance of which is enlivened in the latter part of summer by its abundant pink blossoms. When growing erect to the height of 3 ft. or more, as it often does in sheltered places, its purple stems, close-leaved green shoots and feathery spikes of bell-shaped flowers render it one of the handsomest of the heaths; but on the bleaker elevations and more arid slopes it frequently rises only a few inches above the ground. In all moorland countries the ling is applied to many rural purposes; the larger stems are made into brooms, the shorter tied up into bundles that serve as brushes, while the long trailing shoots are woven into baskets. Pared up with the peat about its roots it forms a good fuel, often the only one obtainable on the drier moors.

The shielings of the Scottish Highlanders were formerly constructed of heath stems, cemented together with peat-mud, worked into a kind of mortar with dry grass or straw; hovels and sheds

for temporary purposes are still sometimes built in a similar way, and roofed in with ling. Laid on the ground, with the flowers above, it forms a soft springy bed, the luxurious couch of the ancient Gael. The young juicy shoots and the seeds, which remain long in the capsules, furnish the red grouse of Scotland with the larger portion of its sustenance; the ripe seeds are eaten by many birds. The tops of the ling afford a considerable part of the winter

fodder of the hill flocks, and are popularly supposed to communicate the fine flavour to Welsh and Highland mutton, but sheep seldom crop heather while the mountain grasses and rushes are sweet and accessible. Ling has been suggested as a material for paper, but the stems are hardly sufficiently fibrous for that purpose. The purple or fine-leaved heath, *E. cinerea*, one of the most beautiful of the genus, abounds on the lower moors and commons of Great Britain and western Europe, in such situations being sometimes more prevalent than the ling. The flowers of both these species yield much honey.

FROM "FLORA DANICA," 1767

FINE-LEAVED HEATH (*ERICA CINEREA*), ONE OF THE MOST BEAUTIFUL SHRUBS OF THE HEATH FAMILY

The genus contains about 500 known species, by far the greater part being indigenous to the western districts of South Africa, but it is also a characteristic genus of the Mediterranean region, while several species extend into northern Europe. No species is native in America, but ling occurs as an introduced plant on the Atlantic side from Newfoundland to New Jersey. Five species occur in Britain: *E. cinerea*, *E. Tetralix* (cross-leaved heath), both abundant on heaths and commons, *E. vagans*, Cornish heath, found only in West Cornwall, *E. ciliaris* in the west of England and Ireland and *E. mediterranea* in Ireland. The last three are south-west European species which reach the northern limit of their distribution in the west of England and Ireland. *E. scoparia* is a common heath in the centre of France and elsewhere in the Mediterranean region, forming a spreading bush several feet high. It is known as *bruyère*, and its stout underground rootstocks yield the briarwood used for pipes.

HEATHCOAT, JOHN (1783-1861), English inventor, was born at Duffield near Derby on Aug. 7, 1783, and was apprenticed to a framesmith. In 1808 he constructed an extremely complicated machine, capable of producing an exact imitation of real pillow-lace. A mill at Loughborough for the exploitation of the new process owned by Heathcoat and his partner Lacy was attacked by the Luddites in 1816, and the 55 lace frames destroyed. Heathcoat now constructed new and greatly improved machines in an unoccupied factory at Tiverton, Devon, propelling them by water-power and afterwards by steam. He invented many other useful processes in connection with silk manufacture. He died on Jan. 18, 1861, at Bolham House, near Tiverton.

HEATHCOTE, SIR GILBERT (c. 1651-1733), lord mayor of London, was educated at Christ's college, Cambridge, afterwards becoming a merchant in London. He was one of the promoters of the new East India company and emerged victorious from a contest between himself and the old East India company in 1693; he was also one of the founders and first directors of the Bank of England. He died in London on Jan. 25, 1733.

HEATHEN, a term originally applied to all persons or races not holding the Jewish or Christian belief, but now more usually given to polytheistic races. See PAGAN.

HEATHER, a plant name properly applied only to *Calluna vulgaris*, also termed ling, but often used loosely to include the heaths (*Erica*) in addition. (See ERICACEAE.)

HEATHFIELD, GEORGE AUGUSTUS ELIOTT, BARON (1717-1790), British general, a younger son of Sir Gilbert Eliott, Bart., of Stobs, Roxburghshire, was born on Dec. 25, 1717. As a volunteer he fought with the Prussian army in 1735 and

FLOWERING BRANCH OF THE LING OR HEATHER (*CALLUNA VULGARIS*) In flower, the small corolla is concealed by rose-coloured sepals, at base of which are four small green bracts

1736, and then entered the Grenadier Guards. He went through the War of the Austrian Succession, and was wounded at Dettingen. In 1775 he was selected to be governor of Gibraltar (*q.v.*), and his magnificent defence in the great siege of 1779 made his name famous. In 1787 he was created Baron Heathfield of Gibraltar, and died on July 6, 1790.

HEATH HEN (*Tympanuchus cupido*), a North American grouse, allied to the prairie chicken (*q.v.*) but smaller and inhabiting wooded districts. Between 1800 and 1850 the heath hen was found locally in southern New England and throughout the Middle States. It subsequently disappeared from all parts of its range except the island of Martha's Vineyard, Mass., where in 1907 it had decreased to less than 100 living birds. Owing to protective measures then established its numbers increased, but in the spring of 1930 only one bird was found.

HEATING AND VENTILATION. These two subjects are so closely allied that they will be treated together. They deal with the science of maintaining in buildings the proper temperatures and atmospheric conditions for the health and comfort of human beings.

History.—The earliest known method of artificial heating was the open fire of prehistoric days. As mankind gradually learned to build dwellings, the fireplace with its chimney was developed as a means of enclosing the fire and carrying off the products of combustion. Later the stove was invented and steadily improved, and is still an acceptable method of heating under certain conditions. The next development was the warm air furnace which made it possible to remove the heating apparatus from the living quarters. As buildings became larger and requirements more exacting, the steam and hot water systems were developed.

Ventilation was not given much attention until relatively recent times. One of the earliest recorded attempts at artificial ventilating was a study of the ventilation of the Houses of Parliament by Sir Humphry Davy in 1811. Thorough scientific research into the true principles of ventilating was not carried on until the last decade and, although excellent progress has been made, there is still much to be learned about the physiological effects of atmospheric conditions as well as the design and operation of the mechanical apparatus.

The General Problem.—Heat is continually being generated by the physiological processes of the human body and must be continually dissipated to the surrounding atmosphere. Comfort, health and working efficiency require that the atmospheric conditions in occupied buildings be such that the loss of heat from the body will take place at the proper rate. This heat is dissipated in several ways; there is direct radiation and conduction from the skin, a considerable amount passes off with the exhaled breath, and much is removed by the evaporation of moisture from the lungs and of perspiration from the skin. The overall cooling effect of the atmosphere upon the body depends upon three conditions—the temperature of the air, its humidity and its rate of motion. They control the heat conduction from the body surface and the rate of evaporation of the perspiration which is almost constantly, though often imperceptibly, being exuded. The higher the temperature and humidity and the slower the movement of the air currents passing over the body, the greater the feeling of warmth. For comfortable conditions the combination of these factors must be correct although each may vary between certain limits. For example, when the atmosphere in a room is very dry the temperature must be maintained considerably higher for comfort than if the atmosphere contained more moisture. The cooling effect of a fan, especially when the skin is bathed in perspiration, illustrates the effect of air motion. The interrelation of these factors has been quantitatively studied, as will be brought out later.

It is the function of the heating and ventilating apparatus to maintain these correct atmospheric conditions within the building. In the great majority of buildings a simple heating system only is provided, and no attempt is made to maintain a definite air movement or to control the moisture content. But where a large number of people are gathered or when it is desired to maintain the best possible atmospheric conditions, ventilating apparatus, often in

combination with the heating apparatus, is provided. The two systems are necessarily parts of the same problem.

The heating system must supply enough heat to replace that which is continually being dissipated from the building in cold weather and must also be adequate to warm up the structure itself after it has been allowed to cool. This heat is lost from the building in several ways. There is direct conduction through the walls, roof and other exposed surfaces, and particularly through the window-glass. There is also a loss due to the infiltration of cold air and a corresponding outward leakage of warm air under the influence of the wind and from other causes. This leakage takes place through the cracks around windows, doors and elsewhere, and even to some extent through the walls themselves. There is a loss of heat occasioned also when windows are left open for ventilation or when ventilating fans discharge air from the building. Besides increasing the infiltration loss, wind movement also increases the heat transmission through the walls and roof, and this fact must be taken into consideration.

The amount of heat required by a building can be computed in advance of its construction, with fair accuracy, by a study of the various sources of heat loss. The heat-conducting properties of all common building materials and types of wall construction are known and are to be found in engineering handbooks. The following are coefficients for some common forms of building construction.

Construction	Coefficient of heat transmission*
Brick wall 4 in. thick66
" " 9 in. "358
" " 13 in. "278
Limestone or sandstone 8 in. thick556
" " 12 in. "457
Wood walls:

Ditto with 1½ in. corkboard insulation110
Concrete roof—4 in. thick568
Single windows and skylights	1.13
Double " " "45

*Expressed in B.T.U. per hr., per sq.ft., per 1° F difference in temperature between the air on the two sides, with an outside wind of 15 m. per hour.

The infiltration loss is computed either by assuming a certain number of air renewals per hour, varying from ½ to 3 for different kinds of rooms, or by computing the length of the cracks around windows and doors and estimating the leakage therefrom, the cracks being the chief source of infiltration. A complete calculation of the heat losses with suitable corrections for exposure on the colder sides of the building thus serves as the basis for the selection of the proper size of the boiler, pipes, radiators and other parts of the heating system. Where the building in question is small or where the heating is not important, such calculations are omitted, but in all modern buildings where the heating is at all important the architect or engineer makes a complete study of the requirements.

HEATING SYSTEMS

The Fireplace or Grate, of which various modifications and improvements have been made from time to time, consists essentially of a basket which holds the fire (or andirons if logs are the fuel), an opening backed by brick which becomes heated by the fire and radiates heat to the room, and a chimney. The grate is an inefficient form of heating because most of the heat imparted to the air which is supplied to the fire passes up the chimney and is lost. In the best designs of open grates only about 20% of the heat in the fuel is actually delivered to the room. Because of this, and because of the impossibility of comfortably heating a building in a severe climate with grates, and also because of the dirt and labour involved, the grate is not used as a primary means of heating in North America. In Great Britain and elsewhere, where the climate is relatively mild, the fireplace is still in general use; the psychological effect of the open fire has also caused it to be retained even where more complete means of heating are provided.

The Stove.—The stove is an improvement over the grate from the standpoint of economy. The modern baseburner stove makes use of from 70 to 80% of the heat in the fuel, but it delivers its heat almost entirely by radiation and is, therefore, not a particularly comfortable method of heating. The stove is being rapidly discarded in America, where formerly it was widely used, because of the attention and space it needs, its unsightly appearance and the fact that a separate stove is required in every room for satisfactory results.

The Warm Air Furnace.—The warm air furnace is the natural outgrowth of the stove. The furnace consists of a firepot and an extended flue, the whole being surrounded by a sheet metal casing (fig. 1). Air passes through the casing, absorbing heat from the hot surfaces of the firepot and flue, and flows through pipes to the various rooms. In the simplest type, the so-called pipeless furnace, the heated air is delivered only to the room directly over the furnace and passes into the other rooms through open doorways by natural circulation. For any but the smallest houses, a furnace having separate pipes to the individual rooms is necessary for good results. The air supply to the furnace may be taken from outside, but in order to save fuel is usually

BY COURTESY OF THE DETROIT EDISON COMPANY

FIG. 1.—DIAGRAM OF WARM AIR FURNACE SHOWING HOW PIPES CONVEY THE HEAT INTO VARIOUS ROOMS

partially or wholly recirculated from the rooms through a system of return ducts.

The warm air furnace, properly installed, is a fairly satisfactory method of heating small homes and is the standard method for such purposes in many parts of America. It is economical in fuel consumption and humidification can be obtained by means of a pan of water placed above the dome of the furnace in the path of the warm air. The fundamental difficulty with the warm air furnace is that since the force which produces the flow of warm air to the rooms depends only upon the difference in temperature between the heated and unheated air, the flow is not always positive and is sometimes affected by the wind. Also the pipes must be short and direct, and rooms distant from the furnace can seldom be satisfactorily heated. The circulation can be augmented by the use of a fan in the air-piping, and this method has found some favour; the fan is needed only in severe weather. Best results are obtained when the air pipes are specially designed for the fan system.

The Steam Heating System.—This type consists of a boiler in which steam is generated, a number of so-called radiators located in the various rooms, and a system of pipes to convey the steam to the radiators and to carry the water of condensation back to the boiler. The heat which has been imparted to the water in the boiler to form the steam is given up as the steam condenses in the radiators and is transmitted to the air of the room. There are several forms of steam heating systems, differing principally in the arrangement of the piping. The simplest is the single-pipe system shown in fig. 2. There is a large horizontal main pipe which leaves the boiler and circles the basement, branches leading to the individual radiators. In large buildings this main is often placed overhead, in the attic. The connection is made to the supply-valve at the bottom of the radiator and the water of condensation trickles back down the steam pipe to the

horizontal main and thence back to the boiler. The air which is originally in the system is forced out by the pressure of the steam through air-valves on each radiator and at other points along the system. These air-valves close automatically when the steam reaches them, thus preventing the escape of steam; they are also supposed to prevent the escape of water. A steam pressure of 1 to 5 lb. per sq.in. is used.

The single-pipe system is a simple, fairly satisfactory system for such buildings as factories and warehouses and is also used

BY COURTESY OF THE DETROIT EDISON COMPANY

FIG. 2.—DIAGRAM OF AN APARTMENT HOUSE EQUIPPED WITH A SINGLE-PIPE STEAM-HEATING SYSTEM, SHOWING THE SIMPLE ARRANGEMENT OF PIPES AND AUTOMATIC AIR-VALVES

in many houses. Its chief disadvantages are the noise, smell and drip which often accompany the action of the automatic air-valve. Also the radiators sometimes fill with water and a violent hammering action takes place.

The Two-pipe System (fig. 3), which is somewhat more costly to install, overcomes these drawbacks. There is a separate system of piping for carrying off the air and condensation, and the air is discharged from the system at a single point in the basement. The supply-valve is placed at the top of one end of the radiator

BY COURTESY OF THE DETROIT EDISON COMPANY

FIG. 3.—TWO-PIPE STEAM-HEATING SYSTEM, CALLED A VAPOUR SYSTEM

and the so-called return connection is made at the bottom of the opposite end through a device called a thermostatic trap which permits the air and condensation, but not the steam, to pass into the return pipe. This system when used in a house or small building will circulate with only a few ounces of pressure at the boiler and is, for this reason, often called a *vapour* system. It operates practically without noise and is somewhat more economical in fuel consumption than the single-pipe system.

The Vacuum System is used in large buildings. It is a two-pipe system with a vacuum pump attached to the return piping.

A partial vacuum, equivalent usually to about 10 in. of mercury below atmospheric pressure, is carried, and the circulation is greatly improved thereby. Radiators and piping located below the boiler can be operated successfully, which would not be otherwise possible. The vacuum pump returns the water of condensation to the boiler or to a tank from which it is pumped to the boiler. The vacuum steam system is the standard method

BY COURTESY OF THE DETROIT EDISON CO.
FIG. 4.—TWO-PIPE HOT WATER SYSTEM, SHOWING THE SEPARATE SUPPLY AND RETURN MAINS

of heating blocks of offices, large retail stores, hotels and similar buildings in America. The piping for a steam-heating system must be carefully designed to secure satisfactory operation. The pipe sizes must be so chosen that the required quantities of steam will flow at a low velocity to avoid noise and permit proper drainage of the condensation. The slope of horizontal pipes must be correct so that the pipes will drain correctly; for accumulations of water at low points will often cause the annoying tapping noise called "water hammer."

Provision must also be made for the free expansion of the pipes due to changes in temperature. In the vertical risers of tall buildings it is necessary to provide loops which absorb the expansion by their flexibility, or slip joints consisting of one sleeve which slides within another.

The Hot Water Heating System.—In this system heat is conveyed to the various rooms by hot water which circulates through the radiators and returns to the heater for reheating. In the simple gravity type the circulation is produced by the difference in density of the hot water in the pipes supplying the radiators and the cooler water in the return pipes which bring the water back to the heater.

There are two different piping arrangements in common use. In the two-pipe system the supply and return pipes are separate as shown in fig. 4. In the single-pipe system the supply for each radiator is taken from the single main pipe and the return connection made at a point farther along the pipe. This system requires less piping but if there are many radiators, the size of those farthest along the main pipe must be increased because they receive cooler water than those near the heater. An expansion tank, usually placed at the top of the system, is required to accommodate the changes in the volume of the water with changing temperatures. Most hot water systems operate at a maximum temperature on leaving the heater, of about 180° F. A higher temperature is practicable only if the water is subjected to pressure to prevent it from boiling.

BY COURTESY OF THE DETROIT EDISON CO.
FIG. 5.—IRON RADIATOR

The fundamental difficulty with the gravity type of hot water system is that the force producing circulation, being due only to the slight difference in densities of the water in the different parts of the system, is very small and the circulation is therefore easily hindered by any sort of restriction in the piping. The successful design of a large hot water system therefore requires the selection of the proper pipe sizes and the proper arrangement of the pipes so that the required quantity of water will flow to each radiator. The dynamics of the flow condition are somewhat complicated but, briefly, a condition of equilibrium becomes established in which the flow of water reaches such a magnitude that the force producing circulation is exactly balanced by the frictional resistance. The selection of the proper pipe sizes is thus of considerable importance and the design requires more care than does a steam-heating system.

In large buildings it is not practicable to depend upon the force of gravity to produce the flow, and a pump is installed in the circuit. In such a system of forced circulation the differential pressure through the system is from 20 to 40 lb. and much smaller pipes can be used than in the gravity system, with resulting economy in construction cost.

The hot water system gives a less fluctuating output of heat to the rooms than the steam system because of the thermal capacity of the circulating water, but is for the same reason less readily capable of responding quickly when more or less heat is required.

BY COURTESY OF GRANE CO., LA CROSSE, WIS.
FIG. 6.—HEAT CABINET WITH COPPER TUBES AND FINS ATTACHED

Because of the lower temperature of the radiators it produces more comfortable room conditions than does the steam system. Another advantage is that the heat output of the radiators can be controlled by varying the water temperature, which is an advantage from the standpoint of economy in large buildings. The hot water system is not well adapted to tall buildings because the water pressure in the lowest radiators becomes very high (about 4.3 lb. for each 10 ft. of building height). Also it requires more careful design than the steam system. It is much used in homes and is regarded by many as the most desirable method of residential heating, although the cost of installation is from 10 to 20% more than that of the simplest steam system. It is used to some extent in office buildings and hotels in America and is particularly popular in Europe for such buildings. In America there are many hot water systems used to supply groups of buildings such as hospitals and educational institutions.

Radiators.—In both the steam and the hot water heating systems there is placed in each room one or more heating elements which are somewhat improperly called "radiators" and, in Great Britain, "the heating apparatus." They consist of pipe coils or of hollow cast iron sections joined together so as to give a large surface area; the heat is given off partly by radiation and partly by convection, i.e., by currents of air which are heated as they pass through the radiator. It has been demonstrated and is, in fact, a matter of common experience that, from a standpoint of comfort, a room heated by convection currents is more comfortable than one heated by radiant heat, hence the tendency is toward methods by which the heat is delivered by convection rather than by radiation.

BY COURTESY OF THE DETROIT EDISON CO.
FIG. 7.—HEAT DIFFUSER WITH A FAN, USED IN LARGE BUILDINGS

Fig. 5 shows the common form of cast iron radiator, which is built in sections of various sizes and assembled as required to give any size desired; the sections are connected at both top and bottom. A slightly different design with connections between the sections at the bottom only was formerly used for steam-heating systems only, but this form, having no particular advantage, has been discontinued by most American manufacturers.

Heating units which deliver their heat almost entirely by convection are in frequent use in America. This design consists of an element having a surface which is greatly extended by means of fins and which is housed in a cabinet giving a flue effect and causing a rapid circulation of air. One form has a copper tube with thin copper fins attached (fig. 6); the cabinet may be concealed in the wall, thus relieving some of the unsightliness of the ordinary radiator.

In large areas, such as in factory buildings, it has been found desirable to use, instead of numerous ordinary radiators, a few heat diffusing units consisting of a fin-type heating element with a fan forcing a large quantity of air through it (fig. 7). This method is quite satisfactory in certain circumstances.

Boilers and Fuels.—The boiler used for heating buildings of moderate size usually has the furnace or firepot incorporated in it; it is usually made of cast iron, which is a suitable material because of the low pressures carried, and is built in sections which are easily handled and assembled. Recently, in America, the steel welded boiler has been introduced, welding being permitted by law for this class of work. In larger buildings where cast iron boilers would be prohibitively large, the riveted steel boiler is used.

The design of the boiler is considerably influenced by the character of the fuel which is to be burned. For anthracite coal or coke a simple firepot with a shaking grate is all that is required. These fuels are ideal from the standpoint of smokelessness. The semi-bituminous coals (called "smokeless" coals), having less volatile matter than the true bituminous coals, can also be burned fairly satisfactorily in the simple firepot, but for bituminous coals special provisions are necessary to avoid excessive smoke. These consist usually of means of introducing heated air at the proper place in the combustion process so that the volatile matter is consumed before striking the relatively cold boiler surfaces.

The efficiency of the usual form of heating boiler is not particularly high. The small boilers operated by the average household probably deliver less than 50% of the heat in the coal to the water in the boiler. In larger installations the results are somewhat better, reaching 75% in the more elaborate plants.

In some sections of America oil is quite commonly used as a fuel. It requires a special burner which can be applied to any style of boiler.

Natural gas is used in certain restricted localities and recently artificial gas has been used in places where its cost is low and where the luxury value of this method of heating is appreciated. Boilers designed particularly for gas are essentially different from those used for coal. Whereas the latter are designed to absorb the large amount of radiant heat from the fuel bed, the gas-fired boiler receives its heat almost entirely from the products of combustion as they pass over the heating surfaces. Also, the gas boiler is designed for good efficiency because of the high cost of gas. Heating with artificial gas is only practicable when the house is well constructed, preferably with insulated walls, and when the advantages of freedom from dirt, ashes and care are of value.

Boilers used for heating with electricity are usually designed with heating elements of the submerged resistance type.

Humidification.—The atmosphere in a building is being more or less frequently renewed through leakage, and the outside air, though it may contain nearly the maximum possible amount of moisture at its original temperature, has its capacity for holding moisture greatly increased as it reaches the indoor temperature and therefore has a drying effect upon the skin and the membranes of the respiratory passages as well as upon furniture, woodwork, etc. Health authorities advocate artificial humidification to alleviate this condition and various devices have been contrived for this purpose.

For hot water and steam systems they usually consist of a wick or pan attached to the radiator. In the warm air furnace system humidification can be quite easily accomplished by means of an evaporating pan located in the air passage of the furnace. That humidifying devices are not always effective is usually due to the lack of appreciation of the quantity of water that must be evaporated. For example, with an outside temperature of 20°, about 1 gal. must be evaporated every 24 hrs. for each 1,000 cu.ft. of room volume to bring the relative humidity to 40%, which is about the proper point. In England and elsewhere, where the outside temperatures are not low and the climate is moist, humidification is rarely needed. Although the temperature required for comfort is somewhat lower when the air is humidified

there is no appreciable saving in the amount of fuel required because of the heat which must be used to evaporate the water for humidifying.

Electric Heating.—Electricity is in many respects an excellent heating medium but its use is limited because of its cost. When electricity is generated by means of the combustion of coal the process involves a loss of 75% or more of the heat in the fuel; and further losses in transmission and the cost of the transmission system make the cost of heating excessive as compared with other methods. It is therefore used only for small rooms and as an auxiliary to other means of heating. Where the electricity is generated by water power, however, the cost is often very much less and in certain cases may compare favourably with that of coal, if the latter is high priced in that locality. This is true in some districts in western United States and Canada and in some parts of Europe.

Temperature Control.—Since the amount of heat which a building requires varies so greatly with different weather conditions, some means are necessary to control the supply. In the small warm air, steam or hot water systems adjustment of the furnace dampers is the simplest method, but this requires attention and is not wholly satisfactory. A thermostat may be used to control the dampers according to the temperature in the rooms; in its simplest form this consists of a temperature-sensitive element located at a properly selected point and arranged so that it operates a small electric motor, as the temperature rises or falls, to close or open the dampers.

When automatic temperature control is provided in large buildings it must be arranged so as to control the temperature in each room individually. Most systems use compressed air as the motive power for operating the radiator valves, controlled by one or more thermostats located in each room. The radiator valves (or the dampers in the case of a ventilating system) are equipped with rubber or metal diaphragm chambers so designed that, as air pressure is applied, the valve or damper will close. The thermostatic element on the wall opens and closes an air supply valve in the pipe leading to the diaphragm chamber so as to maintain the temperature at which its dial is set. Thermostatic control is frequently used in public buildings, hotels, office buildings, etc. It is almost a necessity in the case of a ventilating system.

Central Heating.—In Great Britain, and in Europe generally, the term *central heating* usually refers to the heating of a building by means of one heating unit instead of fireplaces or stoves in every room. As understood in North America, however, it means the supplying of heat to a number of separate buildings from a central plant. When portions of a city are thus heated the term *district heating* is often synonymously used.

The first central-heating system was installed at Lockport, N.Y., in 1877 by Birdsill Holly. Other systems were built from time to time in various cities and there are at present extensive systems in New York city, Detroit, Pittsburgh, Rochester and St. Louis and in a number of smaller cities and towns in America. The areas covered are sometimes 1 or 2 sq.m. or more in extent and include business districts and high class residential districts. Also many groups of factory and institutional buildings are heated from central plants.

Either steam or hot water may be used as the medium for conveying the heat from the central plant; many of the earlier systems are hot water systems and this method is still in use for small groups of buildings. It makes possible the control of the heat supply from the central plant by adjusting the water temperature and is quite satisfactory in institutional work. A double set of underground pipes composing the supply and return systems is installed and the water is circulated by means of pumps. For commercial district heating, however, hot water has several disadvantages. It is impracticable to meter the amount of heat used by each consumer because of the lack of a suitable meter; and it is not feasible to supply tall buildings because of the high pressures that would be required to serve the topmost radiators. Consequently district heating in all of the larger cities is effected by the steam system.

Most of the first steam systems were designed with the idea of utilizing the exhaust steam from engines driving electrical generators and for steam pressures between 2 and 10 lb. per sq.in.; later it was sometimes found more desirable to use live steam direct from the boilers and distribute it at a higher pressure. The passing of the steam through engines or turbines, which drive electric generators, before distributing it for heat-

BY COURTESY OF THE DETROIT EDISON COMPANY

FIG. 8.—CROSS-SECTIONS OF CONDUITS FOR UNDERGROUND PIPES

ing purposes is, from a standpoint of fuel consumption, an economical procedure. The electricity thus generated is produced at a very low fuel cost as compared with the usual method of generation in which a large proportion of the heat of the fuel is carried away by the water circulating through the condensers (see POWER GENERATION). On the other hand, a low pressure distribution system requires much larger pipes because of the greater volume of the low pressure steam and the cost of installation is therefore much higher. In fact, in large cities it would be impossible to install pipes large enough to carry, at pressures below 10 lb., the quantities of steam required. This fact, together with the added cost of the electrical generating machinery, has sometimes made it appear more expedient, commercially, not to generate electricity in the heating plant, notwithstanding the apparent economy of this method. There are, however, a number of heating plants in which some electricity is generated and the present development of boilers and turbines for higher steam pressures and higher exhaust pressures will undoubtedly have a considerable effect upon future practice in this respect.

The steam-distributing pipes are laid beneath the streets or alleys, either inside a conduit buried in a trench, or in a tunnel large enough for men to walk in. The latter method, while allowing inspection of the pipe and facilitating repairs, is naturally much more costly and is justified only when several pipes are to be laid along the same route or where sub-surface conditions do not permit the use of the conduit construction. Various forms of conduits are shown in fig. 8. They are designed so as to prevent excessive loss of heat and to protect the pipe from water and from earth pressure. They are built of wood, vitrified clay, brick or concrete, and so constructed as to leave a space around the pipe to permit its free linear expansion due to changes in temperature. Heat insulation consisting of magnesia or asbestos 1 or 2 in. in thickness, surrounds the pipe except in the case of the wooden conduit, in which the wood itself is the insulator. Underdrainage of the conduit is very necessary in order to carry off ground water. It is provided by a layer of crushed stone or coarse gravel below the conduit with a drain tile, laid with open joints, which leads to some sewer or other outlet.

The heat loss from well constructed underground pipes in dry soil is less than is generally supposed, owing to the insulating effect of the soil. It varies from 40 to 80 B.T.U. per hour per sq.ft. of pipe surface. Further reduction of the heat loss could be obtained by thicker insulation but would not warrant the increased cost. In well maintained systems the efficiency of distribution, which is the ratio of the steam delivered to the consumer to the steam sent out from the central plant, varies from about 80% to as high as 95%, the latter being possible only for

a small system serving a dense load.

The linear expansion and contraction of the pipes due to changes in temperature must be provided for. With a steam pressure of 20 lb. per sq.in., for example, the pipe will increase in length about 1.6 in. in each 100 ft., from its length when cold. To provide for this movement there are two general types of expansion fittings. One of them, the slip joint, consists of a sleeve sliding within another, with suitable packing to prevent steam leakage; others make use of flexible diaphragms or corrugated copper sleeves. Expansion fittings are placed at regular intervals with anchor points midway between to control the direction of the movement.

The life of the underground pipes depends upon the design of the conduit and the nature of the soil. The chief cause of damage is ground water which corrodes the pipe and is difficult to exclude entirely. Pipes installed in well constructed concrete or tile conduit in fairly well drained soil will last for 30 years or more. Wood casing is much shorter lived and is good for only 10 to 20 years as a rule.

The distance over which steam can be transmitted is much greater than is commonly supposed, being limited only by the size of the pipe and by the pressure available. Pipes a mile or two in length are not uncommon and a distance of several miles is quite feasible, though probably not economical. The pressure loss can be closely estimated.

The usual scheme of distribution consists of a central trunk main of large diameter near the plant and decreasing in size, with lateral branches at the intersecting streets. Some systems make use of feeder pipes which radiate to strategic points in the distribution system. Long distance gauges, electrically operated, are used to record, at the plant, the pressure at remote points in the system. The condensation from the consumers' radiators is returned to the plant in most small systems serving only a few buildings, but in large systems it is frequently discharged to the sewer, unless the cost of water is very high, because of the expense of return piping and the difficulty of returning the water without pumping.

In addition to its use for heating buildings the steam is used in small quantities for other purposes. Cooking and laundry apparatus use steam and are satisfactorily served from the central plant if sufficient pressure is available. Cooking equipment is usually designed for steam pressures of 25 lb. or higher. Some steam is used for the heating of water for domestic purposes and, in a few cases, for producing power in steam driven pumps, etc.

Central Heating Costs.—The charge for heat supply is based upon the amount of steam used, which is measured either by a steam flow meter located at the point of supply in each building, or by a meter which measures the amount of condensate drained from the radiators. The latter method is more common and is quite satisfactory. The heat is usually removed from the condensate before it is discharged to the sewer by passing it through an economizer which heats the water supplying lavatories, etc. The water is passed through the economizer, which consists of a cylindrical tank in which a coil or a bundle of tubes, through which the condensation flows, is submerged.

The overall efficiency of the central-heating system compares favourably with that of the individual boiler plant. The better boiler efficiency in the more elaborate and refined central plant balances, to a great extent, the losses in distribution. The efficiency of the modern central plant is from 75 to 85%; the efficiency of distribution is from 80 to 90%; and about 90% of the heat delivered to the consumers' buildings is actually utilized (there being some loss in the condensate). The combination gives an overall efficiency of perhaps 60% in the average case. This is to be compared with an average efficiency of 50% or less for the small coal-fired boiler and perhaps 65% for the large plant; and with 60 to 75% for gas or oil, varying with the size of the plant. The charges for heating service range from about \$.60 to \$1.25 per 1,000 lb. of steam, varying with the size of the building and local conditions. The cost of service is naturally higher in larger cities and where the cost of fuel is high; it compares favourably

with that of the individual plant, particularly where the space occupied by the latter has a rental value. The service is popular in cities where the luxury value is appreciated. To the large-building owner as well as to the householder the freedom from the dirt and nuisance of operating a boiler plant is attractive. There is also an advantage to the community in the reduction of smoke and of dirt from coal and ash hauling.

There are at present approximately 200 commercial district-heating systems in operation in America with an aggregate annual revenue of about \$20,000,000.

VENTILATION

Ventilation is the process and practice of keeping an enclosed place supplied with air proper for human health and comfort and, by analogy, the term is used of exposing any subject to the winds of public criticism [Lat. *ventilare*, from *ventus*, wind]. The air we breathe consists chiefly of two gases, oxygen and nitrogen, with certain small proportions of others, such as carbon dioxide, ozone and argon. Oxygen, which is the active and important constituent, and on which life and combustion depend, forms about one-fifth of the whole, while nitrogen, which is inert and acts as a diluent, forms nearly four-fifths. Of this mixture each adult breathes some 2,600 gal. or 425 cu.ft. in 24 hours. In air that has passed through the lungs the proportion of oxygen is reduced and that of carbon dioxide increased. Of the various impurities that are found in the air of inhabited rooms, carbon dioxide forms the best practical index of the efficiency of the ventilation. The open air of London and of large inland towns contains about four parts by volume of the gas in 10,000 of air. In the country, and in towns near the sea, two to three and a half parts in 10,000 is a more usual proportion. Authorities on ventilation usually take four parts in 10,000 as the standard for pure air and use the excess over that quantity in estimating the adequacy of the air supply.

Ventilation Principles.—Since the atmosphere is thought of primarily as the source of oxygen which our lungs require, it is not surprising that the early theories of ventilation considered only the effect of the atmosphere upon the lungs. For many years it was believed that the effects of poor ventilation were due mainly to the presence of carbon dioxide with perhaps other crowd poisons which exerted their harmful effects through the lungs. It was Flügge who, in 1905, first called attention to the inadequacy of this theory. Working at the Institute of Hygiene at Breslau, he placed human subjects in a tight box, in which the atmosphere soon became oppressive. Allowing them to breathe through tubes air from the outside of the box brought little relief, while other subjects outside the box and breathing its atmosphere through tubes felt no ill effects. From this he concluded that the effect of the atmosphere upon the skin is an important factor in ventilation. Later experimenters, notably Leonard Hill, confirmed these results and it is now generally recognized that the effect of bad atmospheres is primarily physical rather than chemical, and is on the surface of the body rather than the lungs. While it is true that vitiation of the air through the reduction of its oxygen content does take place in crowded rooms, the stuffiness of the atmosphere and the discomfort it produces are mainly due to excessive temperature and humidity and often to bad odours. Appreciation of this fact has greatly aided the development of proper methods of ventilation.

In 1913 Sheppard and E. V. Hill, in America, established by tests a comfort zone which showed, for still air, the relation between temperature and humidity necessary for comfort. More recently Houghten, Yaglou and others, in an investigation sponsored by the American Society of Heating and Ventilating Engineers, the U.S. bureau of mines and the U.S. public health service made elaborate observations of the relations between temperature, humidity and air motion as they affect comfort.¹

The experiments consisted in exposing a large number of persons to carefully controlled atmospheric conditions and recording their sensations as to the relative warmth or coolness of the various conditions. Tests were made in still air and in moving

¹See *Transactions* of the American Society of Heating and Ventilating Engineers for 1923 *et seq.*

air and with the subjects stripped to the waist and normally clothed. The results obtained give the true relationships between temperature, humidity and air motion as they affect human comfort, over a wide range of conditions. For example, with an air movement of 100 ft. per min. and with subjects normally clothed and slightly active, the sensible effect of the atmosphere is the same for the following conditions:—

Relative humidity	Dry-bulb temperature
%	F
20	72.6°
50	70.0°
100	66.7°

Ventilation Requirements.—The various factors entering into ventilation have been given much study. The cooling effect of the atmosphere, which depends upon its temperature, humidity and motion, is the most important factor; but there are other atmospheric conditions which must be considered. Odours play an important part. Body odours, particularly, are objectionable and although no definite harm has been traced to them, modern standards of cleanliness require that they be kept to a minimum. Many complaints of poor ventilation are due to the presence of odours, although all other factors may be correct. The control of odours is an essential element in ventilation. The measurement of odours is very difficult and can only be done in an approximate way by comparison with sample solutions of odours of known strength.

Dust in the atmosphere is another factor that should be at a minimum in a well ventilated room. The dust may be created within the room itself (e.g., by a manufacturing process) or it may enter with the air supplied for ventilation; but it is an element to be considered in arriving at the degree of perfection of the ventilating conditions. The presence of harmful bacteria is undesirable because of the possibility of contagion. Although all bacteria are not harmful the number in the air may generally be taken as indicating the surrounding sanitary condition. The bacteria content of the air is determined by a count of the number of colonies which develop on a culture plate exposed for a short period. Other injurious substances such as gases arising from industrial processes or decaying matter are also elements to be reckoned with.

Dr. E. V. Hill, in America, has suggested a method of ascertaining the degree of perfection of the ventilation in any particular room on the basis of observations made of these several factors, namely, the amount and distribution of the air supply; the cooling effect as indicated by the temperature, humidity and air motion; and the factors of odours, dust, bacteria and other injurious substances. By arbitrarily assigning a scale of penalties for each one of these factors falling short of the ideal condition and combining the results, the degree of perfection of the ventilation as a whole can be computed. This method has been adopted by the American Society of Heating and Ventilating Engineers.

Systems of Ventilation.—To satisfy the requirements it is necessary to provide some means for renewing the atmosphere and it is evident that since the room temperature is a factor in ventilation, the heating and ventilating systems must be considered together. When no special ventilating equipment is provided, acceptable atmospheric conditions are sometimes secured merely through the natural circulation of air through the building, aided by the action of chimneys and open windows, but when many people occupy a room some more positive means must be provided and the air supply must be properly warmed before introduction. There are many kinds of ventilating systems varying from the open window to elaborate fan arrangements, the choice depending upon the type of building and the standard of ventilation it is desired to maintain. The tendency is toward better air conditions in offices, factories and public buildings, steady progress being made in developing improved apparatus and methods. The health and efficiency of office and factory workers is demonstrably improved by a proper atmosphere; and in many manufacturing processes air conditioning is absolutely essential (*see* AIR CONDITIONING).

A complete system of ventilation for buildings in which the best results are desired consists of apparatus for warming, cleaning and humidifying the air, a fan and a system of supply ducts for distributing it to the various rooms, and a system of exhaust ducts with an exhaust fan for removing the foul air. An additional feature, sometimes included, is the cooling of the air, in summer, by artificial refrigeration.

Air Quantities.—The amount of air which should be supplied by the ventilating system varies according to the type of building. The following quantities represent good practice:

Type of building	Air supply	
	Cubic feet per hour per occupant	Number of renewals of room volume per hour
Theatres and auditoriums	600-900	..
Schools	1800	..
Hospitals	2000-3000	..
Toilet rooms	..	20
Offices—general	1200-1800	..
Offices—private	..	4
Public dining rooms	..	4
Basement restaurants	..	8-12
Restaurant kitchens	..	10-20

Minimum quantities for certain classes of buildings are sometimes fixed by State legislation. In many States it is compulsory to provide ventilation for school rooms to the extent of 1,800 cu.ft. per hour per pupil.

Types of Fan Systems.—There are several types of central fan systems in common use. The arrangement depends somewhat upon the extent to which the heating requirements are taken care of by the fan system. The various combinations are as follows: (1) fan system takes care of both the heating and ventilation; (2) it provides ventilation and part of heating, remainder supplied by radiators; (3) it provides ventilation, heat supplied by radiators.

In the first type the air must be delivered at a sufficiently high temperature to heat the rooms and, since the heating requirements vary, provision must be made to deliver air at different temperatures to the different rooms. One common arrangement of this system is shown in fig. 9. The air drawn from outside passes through a tempering heater, is heated to about 40°, then goes through the air washer, secondary heater and fan. Leaving the fan, part of the air passes through additional heaters which are adjusted to bring it to a temperature of from 80° to 160°, depending upon weather conditions; the remainder bypasses these heaters and is at a temperature of about 68°. Individual ducts lead to the various rooms and take their supply partly from a hot air chamber and

BY COURTESY OF THE DETROIT EDISON COMPANY

FIG. 9.—ARRANGEMENT OF VENTILATING SYSTEM WHICH PROVIDES BOTH VENTILATION AND HEAT AT VARIOUS TEMPERATURES FOR DIFFERENT ROOMS

partly from a tempered air chamber, the proportions being regulated by a mixing damper usually controlled by a thermostat located in the room itself. Thus the proper mixture of air is supplied to maintain the room at the desired temperature. In an alternative arrangement the fan system delivers air to a trunk duct with branch ducts to the various rooms and in each branch duct is located a heater, often thermostatically controlled from the room, which adds just the proper amount of heat to the air.

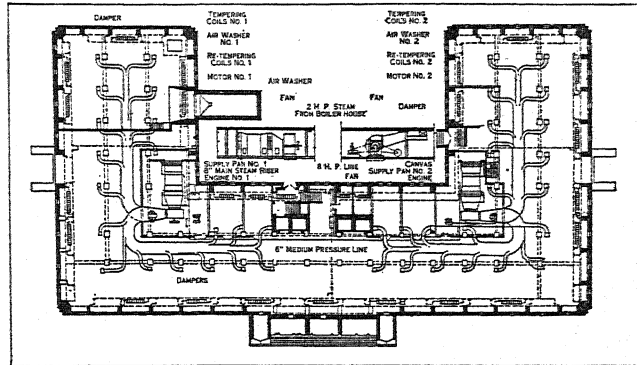

In the second type, when part of the heat is supplied by radi-

ators, the fan system is similarly arranged but the air is delivered at a lower temperature. In severe climates it is desirable to install radiators along the outside walls, particularly under large windows, to avoid local cold spots. This is the justification for this type.

In type 3, since no heating is done by the fan system, the air is supplied to all of the rooms at the same temperature, usually about 70°, and the fan system is therefore simple in arrangement. A trunk duct with branches to the various rooms is used as shown in fig. 10.

It is evident that the first type of fan system must be operated whenever heat is required in the building, while the third type need be used only when ventilation is desired.

Exhaust System.—In modern systems a central exhaust fan is used to withdraw the foul air but in some systems the circulation is produced only by the natural tendency of warm air to

FIG. 10.—BASEMENT PLAN OF BUILDING SHOWING VENTILATION DUCTS

rise, and by the slight pressure produced by the supply fan. Provision is often made for partial recirculation of the air from the exhaust duct to the supply fan so as to avoid the waste of warming unnecessary quantities of fresh air during the heating up period. Also, it is held by some that partial recirculation even in times of full occupancy of the building is permissible, provided the air is passed through an air washer or filter.

The air supply is introduced, in ordinary rooms, usually at points along the inside walls well above head height. Sometimes the inlet grilles are placed in the ceiling, but this requires a much lower air velocity to avoid uncomfortable draughts. An air movement in the occupied zone of the room greater than about 2 ft. per sec. is likely to cause discomfort. In theatres the air is introduced from above and withdrawn through small openings in the floor beneath the seats.

Air-conditioning apparatus (see AIR CONDITIONING) used in ventilation comprises the air washer and the air filter, either or both being used, depending upon the standard of ventilation desired. The function of the washer is to remove dirt and bacteria, to increase or reduce the moisture content and to cool the air in cases where artificial cooling is used. The air filter consists of a metal screen so constructed as to cause the air to flow through it in tortuous paths. The surfaces are wet with a viscous oil which traps the dust particles. This apparatus is more efficient in removing certain kinds of dirt than is the air washer and is used in some cases to supplement the latter.

HEATON, SIR JOHN HENNIKER, 1ST BART. (1848-1914), English postal reformer, was born at Rochester, in Kent, on May 18, 1848, the son of Lt.-Col. Heaton. He spent 20 years in Australia, where he was a well known newspaper proprietor. As M.P. for Canterbury, England, from 1885 to 1910, he advocated penny postage throughout the British empire, and lived to see it achieved and extended to the United States. He died at

Geneva, on Sept. 8, 1914.

See *Life and Letters of Sir John Henniker Heaton, Bart.*, by his daughter, Mrs. Adrian Porter (1916).

HEATSTROKE: see **SUNSTROKE AND HEATSTROKE.**

HEAVEN, the firmament in which the sun, moon, planets and stars seem to be placed; hence also used, generally in the plural, of the atmospheric region (O. Eng. *hefen*, *heofone*, appearing in O.S. *hevan*, is seemingly unconnected with the High Ger. word appearing in Ger. *Himmel*, Dutch *hemel*: its derivation is unknown; it is not connected with "to heave," i.e., "lifted up"). In the cosmogonies of ancient peoples there was a plurality of heavens, varying from three to seven, the higher transcending the lower in glory. Heaven, in the Hebrew *shamayim*, the Greek *οὐρανός*, the Latin *caelum*, is the abode of God, and as such in Christian eschatology is the place of the blessed in the next world (see **ESCHATOLOGY AND PARADISE**).

HEAVISIDE, OLIVER (1850-1925), English physicist, was born in London on May 13, 1850. He was employed by the Great Northern Telegraph Company, Newcastle. Increasing deafness forced him to retire in 1874, when he went to live in Devonshire and devoted himself to theoretical investigations on electricity. Heaviside had some difficulty in getting his papers accepted for publication, probably because he made use of unusual methods of his own in solving his problems. Consequently, in 1892 he published his collected papers in two volumes under the title of *Electrical Papers*. In these papers he dealt with the theoretical aspect of a number of practical problems, such as quadruplex and multiplex telegraphy, electrostatic and electromagnetic induction between parallel wires, and the high frequency resistance and inductance of a concentric main. His work on the theory of the telephone has made long distance telephony practicable. The publication of his papers brought him recognition from men of science. His *Electromagnetic Theory* (vol. i. 1893, vol. ii. 1899, and vol. iii. 1912) also dealt with a number of important problems. He worked out the theory of an electric charge moving with uniform velocity, and predicted the change in the mass of such a charge when the velocity is large. He also suggested the presence of a conducting layer in the upper atmosphere which prevents electromagnetic waves spreading out into space. This layer is now called the Heaviside layer. He died at Torquay on Feb. 3, 1925.

HEBBEL, CHRISTIAN FRIEDRICH (1813-1863), German poet and dramatist, was born at Wesselburen in Ditmarschen, Holstein, on March 18, 1813. The only son of a poor bricklayer, he was brought up under conditions of extreme hardship, which exercised a permanent influence on his life. As his English translator, L. H. Allen, has justly said, he owed to his early environment "his sharp directness of speech, and to his peasanthood a raw facing of unvarnished things that was to stand him in good stead in his future war on faddists and dilettanti." He owed his first appearance in print, in the Hamburg *Modeszeitung*, to Amalie Schoppe (1791-1858), a then popular journalist and author of nursery tales. Through the kindness of this lady, who interested several of her friends on his behalf, he was enabled to go to Hamburg and there prepare himself for the university. A year later he went to Heidelberg to study law, but finding this uncongenial he passed on to the University of Munich, where he devoted himself to philosophy, history and literature. In 1839 Hebbel left Munich and wandered back to Hamburg on foot, where he resumed his relations with Elise Lensing, a poor seamstress, whose self-sacrificing assistance had helped him over the darkest days in Munich. In the same year he wrote his first tragedy *Judith* (published 1841), a drama of poetry and passion, whose performance in Hamburg and Berlin made his name known throughout Germany. In 1840 he wrote the tragedy *Genoveva*, and the following year finished a comedy, *Der Diamant*, which he had begun at Munich. In 1842 he visited Copenhagen, where he obtained from the king of Denmark a small travelling studentship, which enabled him to spend some time in Paris and two years (1844-46) in Italy. In Paris he wrote his fine prose "tragedy of common life," *Maria Magdalena* (1844). The significance of this play in the history of the drama will be realized when it is

noted that it was written when Ibsen was still a lad of 16.

On his return from Italy Hebbel met at Vienna two Polish noblemen, the brothers Zerboni di Sposetti, who in their enthusiasm for his genius urged him to remain, and supplied him with the means to mingle in the best intellectual society of the Austrian capital. The unwonted life of ease had its effect. The old precarious existence became a horror to him, he made a deliberate breach with it by marrying (in 1846) the beautiful and wealthy actress Christine Enghaus, who created the principal parts in many of his plays and thus powerfully helped his career. Much of his best work was inspired by her. In marrying Christine Hebbel sacrificed the girl who had given up all for him and who remained faithful till her death, on the ground that "a man's first duty is to the most powerful force within him, that which alone can give him happiness and be of service to the world": in his case the poetical faculty, which would have perished "in the miserable struggle for existence." The marriage brought a measure of peace and serenity to his stormy and passionate nature. Christine invited Elise to Vienna, and made what amends were possible in the case. The relations of these two noble women are a great example of mutual understanding and forbearance. Shortly after Elise's death Hebbel wrote (1855) the little epic *Mutter und Kind*, intended to show that the relation of parent and child is the essential factor which makes the quality of happiness among all classes and under all conditions equal. Long before this Hebbel had become famous; and in foreign capitals he was fêted as the greatest of living German dramatists. He died at Vienna on Dec. 13, 1863.

Hebbel's principal tragedies are *Herodes und Mariamne* (1850); *Julia* (1851); *Michel Angelo* (1851); *Agnes Bernauer* (1855); *Gyges und sein Ring* (1856), and the magnificently conceived trilogy *Die Nibelungen* (1862), his last work (consisting of a prologue, *Der gehörnte Siegfried*, and the tragedies, *Siegfrieds Tod* and *Kriemhilds Rache*), which won for the author the Schiller prize. Of his comedies *Der Diamant* (1847), *Der Rubin* (1850), and the tragi-comedy *Ein Trauerspiel in Sizilien* (1845), are the more important, but his genius showed itself at its height in tragedy. All his dramatic productions, however, exhibit skill in characterization, great glow of passion, and a true feeling for dramatic situation; their poetic effect is sometimes marred by extravagances of the kind which marred much of the later Elizabethan tragedy. Hebbel's poems, *Gedichte* (1842) and *Neue Gedichte* (1848), show a great lyrical gift. From the age of 20 onwards he kept a diary, and this autobiography is one of the most moving of literary documents.

The best edition of Hebbel's works is that by R. M. Werner (12 vols., 1901 seq.); it includes the "works," the diary and letters. There are many later editions. An English translation *Three Plays by Friedrich Hebbel*, by L. H. Allen, is included in the "Everyman Library." For a full bibliography see Wuetschke, *Hebbel-Bibliographie* (1910). For his life see his own diaries, published in his *Works*; also E. Kuh, *Biographie Friedrich Hebbels* (2 vols., 1877); R. M. Werner, *Hebbel, ein Lebensbild* (1904); A. Farinelli, *Hebbel e i suoi drammi* (1912); R. Ebhardt, *Hebbel als Novellist* (1916); E. Loose, *Friedrich Hebbels Anschauungen über die deutsche Literatur bis zum Ausgang der Klassiker* (1918); L. Brun, *Hebbel, sa personnalité et son oeuvre lyrique* (1919); E. Federn, *Friedrich Hebbel* (Munich, 1920); A. Hallmann, *Das Individualitätsproblem bei F. Hebbel* (Leipzig, 1921); J. Bab, *Das Wort F. Hebbels* (Munich, 1923); K. Strecker, *Friedrich Hebbel, sein Wille, Weg und Werk* (1925).

HEBBURN, urban district, Durham, England, on the right bank of the Tyne, 4½ m. below Newcastle, on the L.N.E. railway. Pop. (1921) 24,168. It has extensive shipbuilding and engineering works, rope and sail factories, chemical, colour and cement works, and collieries.

HEBDEN BRIDGE, an urban district of the West Riding of Yorkshire, England, 7 m. W. by N. of Halifax by the L.M.S. railway. Pop. (1921), 6,459; area 476 acres. The town is situated in a well-wooded steep-sided valley, at the confluence of Hebden Water and the river Calder, and surrounded by wild moorland country. Cotton-factories, dye works, foundries and shuttle manufacturing factories provide occupation.

HEBE [Gr. "young maturity," "bloom of youth"], daughter of Zeus and Hera, *Odyssey* xi. 603. In Homer, this divine princess, in accordance with the simple northern manners of the

Achaean nobles, does housework, much as the human princess, Nausicaa, does the family washing. Therefore she harnesses her mother's horses (*Iliad*, v. 722), bathes her brother Ares (*ibid.*, 905), and pours the wine at table (iv. 2). It is in her capacity as cup-bearer to the gods that she is often mentioned, and is sometimes said to have been superseded by Ganymede (q.v.). As goddess of youth, she is generally worshipped along with her mother, of whom indeed she may be regarded as a sort of emanation or specialized form. She is also combined, both in cult and in mythology, with Hercules (q.v.), whose bride she became when he was received into heaven (*Odyssey*, l.c.). The most important seats of her worship were Phlius and Secyon, where she was called Ganymede and Dia (Pausanias, ii. 13.3; Strabo, viii., 6.24). (See Preller-Robert, I. 489, and the classical dictionaries.)

A Latin deity with whom she is sometimes identified is Iuventas, whom, however, Dionysus of Halicarnassus iv. 15.5, calls Neotes, not Hebe. The hellenized cult of Iuventas-Hebe dates from 218 B.C. (Livy, xxi., 62.9).

See Wissowa, *Religion und Kultur der Römer*, p. 135, and the classical dictionaries.

HEBER, REGINALD (1783-1826), English bishop and hymn-writer, was born at Malpas, Cheshire, on April 21, 1783. He studied at Brasenose college, Oxford, where he won prizes for a Latin poem entitled *Carmen seculare*, an English poem on *Palæstine*, and a prose essay on *The Sense of Honour*. He was elected a fellow of All Souls' (1804), admitted to holy orders (1807) and presented to the family living of Hodnet in Shropshire. Heber became prebendary of St. Asaph in 1812, was appointed Bampton lecturer for 1815, preacher at Lincoln's Inn in 1822, and bishop of Calcutta in Jan. 1823. His devotion to his work in the trying Indian climate told severely on his health. He died at Trichinopoly on April 3, 1826.

Heber's fame rests mainly on his hymns, such as: "Brightest and Best of the Sons of the Morning"; "God, that Madest Earth and Heaven"; "Holy, Holy, Holy, Lord God Almighty"; "From Greenland's Icy Mountains"; "The Son of God Goes Forth to War." He edited (1822) the works of Jeremy Taylor.

See the *Life of Reginald Heber, D.D.* . . . by his widow, Amelia Heber (1830), which also contains a number of Heber's miscellaneous writings.

HEBER, RICHARD (1773-1833), English book-collector, the half-brother of Reginald Heber, was born in London on Jan. 5, 1773. He attended continental book-sales, purchasing sometimes single volumes, sometimes whole libraries. He did not confine himself to the purchase of a single copy of a work. "No gentleman," he remarked, "can be without three copies of a book, one for show, one for use, and one for borrowers." He is known to have owned 150,000 volumes and probably many more. He was member of Parliament for Oxford university from 1821-26, and was one of the founders of the Athenaeum Club, London. He died in London, Oct. 4, 1833.

HÉBERT, JACQUES RENÉ (1757-1794), French Revolutionist, called "Père Duchesne," from his newspaper, was born at Alençon, on Nov. 15, 1757. His family was ruined by a lawsuit and Hébert came to Paris, where he endured great hardships. In 1790 he attracted attention by some pamphlets, and became prominent in the club of the Cordeliers in 1791. On Aug. 10, 1792 he was a member of the revolutionary Commune of Paris. His violent attacks on the Girondists led to his arrest on May 24, 1793, but he was released owing to the threats of the mob. Henceforth very popular, Hébert organized with P. G. Chaumette (q.v.) the "worship of Reason," in opposition to Robespierre's theistic cult. The failure of this movement brought about the arrest of the Hébertists. Hébert was guillotined on March 24, 1794: His influence was mainly due to his violent articles in his journal *Le Père Duchesne*.

See F. A. Aulard, *Le Culte de la raison et de l'être suprême* (1892).

HEBREW LANGUAGE. In the Old Testament, Hebrew is called *sēphath Kēna'an* "the lip of Canaan," or *Yēhūdīth*, "Jewish"; the later Jews designated it *lēshōn haqqōdesh*, "the sacred tongue"; the term *ībhriith*, "Hebrew," was coined by the Rabbis of Palestine. The English name comes from the Greek

ἑβραῖος, "Hebrew," whose adverb ἑβραϊστὶ, "in Hebrew," is applied to Biblical Hebrew in the Prologue to Ecclesiasticus (c. 130 B.C.); this adjective is derived from the Aramaic *ībhray*, "Hebrew."

Hebrew is a Semitic language (see SEMITIC LANGUAGES), and monuments in it range from the 9th or 10th centuries B.C. to the present day. It was a mixed speech, to whose composition elements from several Semitic languages contributed; further, a few primitive words may have come from a non-Semitic people who, archaeology shows, once inhabited Palestine. Egyptian and Babylonian documents prove that a West-Semitic (Canaanite) language resembling Hebrew was current in Canaan before the coming of the Hebrews. Egyptian documents from the 16th century B.C. onwards reveal over 1,200 Semitic words, some common to various Semitic languages, others peculiar to the Syro-Canaanite branch; e.g., Eg.-Can. *nb* (Hebr. *ēnābh*), "grape," occurred in Aramaic and Arabic, but Eg.-Can. *brt* (=Hebr. *bērith*), "covenant," was confined to Hebrew. The feminine nouns preserved the primitive ending *-t*, which had already become *-h* in the Old Testament; e.g., Eg.-Can. *spt* (=Hebr. *ashpāh*), "quiver." In the earlier words the plural and dual took *-n*, as in Aramaic, but later *-m*, as in classical Hebrew; thus the Eg.-Can. *krmy* (c. 1200 B.C.) gave place to *krmy*, which was closer to the Hebrew *kērāmim*, "vineyards" (c. 1100 B.C.). The form in *-n* survived in the North-Palestinian dialect of Hebrew, as *šidōnin* for *šidōnim*, "Sidonians"; similarly the Eg.-Can. *sh-* corresponded with the dialectical Hebr. *she-* (for the correct *āsher*), "who," "which." These texts exhibit many names of places afterwards famous, as well as those of deities like *shrt* (=Hebr. *ashtōreth*), "Astarte," and of persons like *brm* (=Hebr. *abrām*), "Abram," especially in composition. Many terms describing common objects, either in composition or independently, appear early in the texts; e.g., Eg.-Can. *rsh* (=Hebr. *rō'sh*), "head," and Eg.-Can. *kmh* (=Hebr. *qemah*), "flour." Others, having changed their meanings or not having survived in Hebrew literature, emphasize the fact that much has disappeared from the Hebrew vocabulary. The cuneiform correspondence found in Egypt, chiefly between the Egyptian kings and their vassals in Syria and Palestine (c. 1400 B.C.), also exhibits a language similar to, but older than, biblical Hebrew. These letters were written in a Babylonian exhibiting Western peculiarities closely approximate to Hebrew idiom: the Babylonian permissive tense, expressing properly a state, served also to describe a past action, like the Hebrew perfect with whose form it was identical; the Babylonian preterite, like the Hebrew imperfect with which its form agreed, served to express incomplete action in present time; the first person singular of the permissive (perfect) was closer to Hebrew than to Babylonian; e.g., Bab.-Can. *našrāti* (=Hebr. *nāšartī*, not Bab. *našrāku*) "I have kept"; a passive is formed by the internal modification of the vowels; e.g., Bab.-Can. *yudan* (=Hebr. *yuttan*), "is given." This passive type, though unknown in Babylonian, is found sporadically in Hebrew and regularly in Arabic. But the principal evidence lies in the Canaanite glosses which, more than 100 in number, were added to explain Babylonian terms; for they closely resemble pure Hebrew. Thus the Bab. *ina qātishu* is explained by the Can. *badū* (=Hebr. *bēyādōh*), "in his hand," Bab. *elippu*, by Can. *anaya* (=Hebr. *ōnīyāh*), "ship," and so on. Again, the language of these glosses is earlier than Hebrew; e.g., Bab.-Can. *yakwū*, "is," in which the half-vowel *w* is retained, is older than a form like the Hebr. *yāqūm*, "he arises," in which it has been assimilated to the *u* (cf. Pun. *ichon*, "he is"); it preserved also the old feminine *-t*, as in *abadat* (cf. Hebr. *ābhēdhāh*), "is ruined," which rarely appeared in Biblical Hebrew. These texts prove the pronominal suffix *-mō*, which is a late poetical variety of the usual *-m*, "their," to be a genuine archaism; for example, Bab.-Can. *panimu* corresponds with the archaistic Hebr. *pānēmō*, not the classical Hebr. *pēnēhem*, "their face." Most place-names, many of them afterwards found in the Old Testament, and some personal names exhibit purely Canaanite forms; and divine names like the Bab.-Can. *ba'alu* or *dagan*, contained in various proper names, are identical with the Hebr. *ba'al*, "Baal," and *dāghōn*, "Dagon." Clearly, Canaanite, as reflected in these ancient Egyptian and Babylonian texts, though not merely a form of Hebrew, certainly

contributed much to it.

The central group (Aramaic) made some contribution to Hebrew. This is illustrated by certain differences in the vowels: where old Aramaic prefers *a*, Canaanite and Phoenician prefer *u* (*o*), while the alternations in Hebrew betray its composite origin; for example, *rō'sh*, "head," goes back to the Can. and Phoen. *rūsh*, but *rā'shim*, "heads," to the Aram. *rā'sh*. Again, in certain weak verbs Hebrew prefers the Aramaic *a* in the active but the Canaanite *u* (*o*) in the reflexive (passive) voice; for example, the active *naḥti* agrees with the Aram. *nāht* against the Can. *nuḥti*, "I rested," while a form like the passive *nākhōn*, "was established," reflects the Canaanite vocalization. The vocabulary, however, exhibits few words which are undoubtedly old Aramaic.

Another element comes from the Eastern (Accadian or Assyro-Babylonian) branch of the Semitic family. Through this it obtained a few Sumerian loan-words, like *hēkhāl*, "temple," through Acc. *ēkallu*, "palace," from Sum. *E.GAL*, "great house." Those weak verbs, whose last two consonants are identical, show this Accadian (and Aramaic) element; for example, the alternatives *qaṣaṣ* and *qaṣ* represent the Acc. *qasiṣ* and the Aram. *qaṣ* "cut," respectively. Similarly the alternatives *mīshōr* and *mēshār*, "justice," represent the Phoen. *misor* and the Acc. *mīshāru*, "justice," respectively.

A number of alternative words confirms this view. The Hebr. *'ānōkhi* and *'āni* reflect, the first, the Bab.-Can. *anuki* (cf. Acc. *anāku*) and the second, the Aram. *'ānā* (cf. vulgar Arab. *'anī*), "I"; the Hebr. *'ēl* and *'ēlō'āh* reflect the Bab.-Can. *ilu* and Phoen. *el* (cf. Acc. *ilu*) and the Aram. *ēlāhā* (cf. Arab. *'ilāh*), "God," respectively.

There are even occasionally three synonyms each from a different source in current use.

Hebrew, therefore, has drawn upon Assyro-Babylonian, old Aramaean (Amorite) and Canaanite. Now the correspondence from Tallu-l'-Amarnā tells of people called *Ḥabiru* pressing into Syria and Palestine from the north-east and the east. The name can hardly be dissociated from that of the Hebrews (cf. Bab.-Can. *ḥaparu*=Hebr. *'āphār*, "dust," in illustration of the philological equation); but the people are not the biblical Hebrews, if only because of their time and manner of entering Palestine. Cuneiform sources, however, relate that they came from Mesopotamia, through Hittite territory, into Syria and Palestine; so tradition asserts that Abraham came from Babylonia by Haran, through Hittite and Amorite territory, into Palestine. The analysis, too, of the Hebrew language shows that those who spoke it borrowed elements from and therefore in all probability passed through lands whose inhabitants spoke the Babylonian, Amorite (or Aramaean) and Canaanite languages. Thus history and philology confirm the traditional origin of the Hebrew people.

Hebrew retained but few traces of dialect; the reason lies probably in the Masoretic editing of the sacred text, which obliterated all local peculiarities. The Amorites substituted *s* for *sh*; and a trace of this is seen when the Ephraimites said *sibbōleth* for *shibbōleth*. Another mark of dialect was the Gileadite use of *shōmēā* (cf. Ass. *shāmeānu* and Eth. *samā'i*), "hearer," for *'ēdh*, "witness." Again, the North-Palestinian narratives preferred *'attī* to *'att*, "thou" (fem.), *zōh* to *zō'th*, "this" (fem.), and exhibited a few other Aramaizing peculiarities, notably in certain pronominal suffixes. This explanation probably accounts for certain infinitives, like *hālōkh* for *lekheth*, "to go," used by the Elohist. The use of *mēlōkhāh* for *molkhāh*, "rule," *'ālaz* for *'ālaṣ*, "exulted," and *'al*, "upon," for *'el*, "unto," may also be dialectical. But certainty on this point, in view of the lack of sufficient evidence, is unattainable.

Hebrew was written in the common Semitic alphabet, used alike by Moabites, Hebrews, Phoenicians (who transmitted it to the Greeks), and Aramaeans. The earliest Hebrew examples occur on the Calendar from Gezer (c. 8th century B.C.) and on the inscription in the Pool of Siloam (c. 700 B.C.); there are, however, earlier instances in other languages. This character remained longest unaltered in Hebrew and Phoenician. The transition to the "square script" was effected first in Aramaic and later in Hebrew, undoubtedly in consequence of the growing influence of

Aramaic immediately before the Christian era. It was called the "Assyrian script" on the assumption that it was the hand of the Eastern Aramaeans, which the Jews adopted about the 5th century B.C. Tradition ascribed this change to Ezra; but inscriptions, *ostraka* and *papyri*, prove that it was a gradual process which was not completed in Hebrew by 400 B.C. Another form of this hand is found in Egyptian Aramaic in the 5th and 4th centuries B.C. From these were developed the "square" characters used in biblical manuscripts, important texts and most printed books; the "Rabbinic" script, used in every kind of treatise, and the "cursive" writing of letters and informal documents, which was not generally printed. Hebrew palaeography is not sufficiently advanced to determine accurately the date of a manuscript, but the country of its origin can be recognized. The clearest distinctions are between Spanish, French, Italian, Maghrebi, Greek, Syrian and Egyptian, Yemenite, Persian and Karaite hands. This alphabet numbered 22 letters, whose order the evidence of certain acrostic poems proves not always to have been precisely that which afterwards prevailed; and there are signs that it was not definitely fixed even when the Greek version of the Old Testament was made. In default of figures the consonants served also as numerals, of which usage the earliest traces are found on Macca-baeen coins. On these, too, abbreviations, which are unknown in the Old Testament but are extremely common afterwards, make their first appearance.

This alphabet was purely consonantal, except that *w* and *y* could denote *u* and *i*, while ' (*'āleph*) sometimes marked *a* and more rarely *o*, and *h* supported various final vowels; the first two also indicated the diphthongs *au* (*ō*) and *ai* (*ē*). In inscriptions these helping consonants were rarely written and were inserted in the Scriptures only by later scholars, often wrongly. That this alphabet was imperfect, apart from the absence of vowels, is evident; for, firstly, the versions prove that *h* and ' (*'ayin*) each represented a harder and a softer sound, which Arabic distinguishes by diacritical points; secondly, the Masoretes inserted a point in *b*, *g*, *d*, *k*, *p* and *t*, to distinguish their unaspirated from their aspirated sounds. Yet it was over-rich in the possession of five sibilants: *z*, a strongly articulated *s*, two forms of *s* which were so alike that one of them almost fell into desuetude, and *sh*.

The writing was from right to left. On the earliest inscriptions the words were divided by a point; but this was not so on gems and coins, and separation of the words was probably irregular in early manuscripts of the Scriptures; for the versions not infrequently imply a different division. It seems, however, to have been completed, like the introduction of special final forms of *k*, *m*, *n*, *p* and *s*, before the time of the Masoretes. As Hebrew became ever more the language solely of the learned, the need of preserving the original pronunciation in the reading of the Scriptures was increasingly felt; for this the vowel-less text was a very imperfect instrument. The insertion of *w* and *y* (*'āleph*) and *h* to mark long vowels and diphthongs was the first step; that of ' (*'āleph*) and *h* was very early; but, since the Greek version often implies a reading without such a *w* or *y*, they had probably not been generally introduced even after the 2nd century B.C. The system of vowels found in modern Bibles was a much later invention, having been gradually developed by Jewish grammarians in the 6th and 7th centuries A.D., imitating the Syriac vocalization. Two main systems were invented: the Babylonian with mostly supra-linear signs, and the Palestinian, in which they were chiefly put under the line. The Palestinian, as elaborated by the scholars of Tiberias, is that found in modern Bibles. It was so exact as to show all the vowel-changes occasioned by lengthening, by tone, by gutturals, and so on, which other languages seldom indicate in writing. This vocalization, which was little used except in Bibles, represented the traditional pronunciation observed in reading the Scriptures in synagogues and schools; but doubts have, on good grounds, been raised whether it represents the true pronunciation of ancient Hebrew. This can be shown by the Assyrian writing of Hebrew names and by the Greek and Latin transcription of Hebrew names and words. Thus "Dibon" (Hebr. *Dibhōn*) should probably be pronounced "Daibon" (Hebr. *Daibhōn*) if the Greek *Δαῖβων* is to be trusted. (See GREEK

LANGUAGE.) It is also noteworthy that the punctuation often exhibits a later *i* or *e* where the Septuagint preserves an *a* which comparative philology proves to be original. Yet caution is necessary; for the alphabet into which a word is being transcribed may not possess any means of representing the necessary sound; for example, the Assyrian transcription *Ausi* and *Usi* for "Hoshea" (Hebr. *Hôshēā*) does not imply any different pronunciation, since Assyrian had no signs for *h*, *o* and *e*; the Greek *Ωσηε*, as far as it can, here confirms tradition. In fact, although the Masoretic vocalization might sometimes be wrong, internal reasons as well as the analogy of the cognate languages testify to the general faithfulness of the tradition. At the same recension, or soon afterwards, other signs, such as a complicated system of accents, different in the prose-works and the poetical books were added. There are now two pronunciations of Hebrew current, viz., the Polish and German, which partly resembles that of Syriac, and the Spanish and Portuguese, which approaches that of Arabic; Christians, after Reuchlin, generally prefer the latter to the former.

In development Hebrew was later in many respects even than classical Arabic, which hardly began till several centuries after Hebrew had ceased to be spoken. Classical Arabic, like early Babylonian, had case-endings (sing. nom. -u, acc. -a, gen. -i). Of these there are traces of a nom. -û (or -ô), found only with a following genitive case, in the Calendar found at Gezer in which *yarhû* stands besides *yeraḥ*, "month," and sporadically in the Old Testament in names like "Methushael" (Hebr. *Mēthūshā'ēl*, cf. Bab. *mutu shû ilû*, "man of God") and in certain phrases like *hayēthô* (for *hayyath*) 'eres, "beasts of the earth." The acc. -āh survived as an adverbial ending, chiefly denoting place and time; otherwise it had no force, as in *laylāh* (for *layil*), "night" (cf. ḡ *vōkra* for ḡ *vōḡ* in Rōmaic). No genitive ending is found in Hebrew; for the termination -ī, sometimes attached to nouns governing the genitive case, was probably a binding vowel, like the -i of early Babylonian. The plur. -īm and du. -aim were properly acc. endings, as Babylonian (plur., nom. -û and acc.-gen. -ī; du. nom. -ān and acc.-gen. -ēn) and Arabic (plur., nom. -ūna and acc.-gen. -īna; du. nom. -āna and acc.-gen. -aina) show. The Canaanite glosses *shamuma* and *shamema* (cf. Hebr. *shāmāim*), "heaven," show two plural cases; of these the alternative forms of the name "Peniel" (Hebr. *Pēnū'ēl*) and "Peniel" (Hebr. *Pēnū'ēl*), "face of God," of which the plur. *pānīm* (cf. Bab. Ass. *pānū*), "face," is an element, were the sole surviving trace in Hebrew. The earliest Hebrew, then, was on a level with modern Arabic or Greek; for the accusative had become the only case.

Classical Hebrew construction was almost exclusively paratactic, subordinate conjunctions being extremely rare. In pre-exilic writings many verses and even whole chapters can be found, exhibiting no conjunction other than *û*- or *wē*-, "and." Yet there is no monotony; for extraordinary skill is displayed in varying the tenses and the order of the words, often with good effect; e.g., Hebrew says graphically "this do and live" for the ordinary English "if you do this, you will live." Further relief was provided by "wāw-consecutive," a construction almost confined to biblical Hebrew; elsewhere it is found only in one Moabite and one Aramaic inscription, and died out before Mishnaic Hebrew arose. This construction was the normal method of connecting each fresh verb in the narration of a series of events with the preceding clause. Hebrew tenses involved no relations to actions as past or future but only as complete or incomplete: by it, therefore, in past time only the first verb stood in the perfect and the narration was continued in the imperfect; in present or future time, the first verb stood in the imperfect and the subsequent verbs in the perfect. This progress in the sequence of time was indicated by a variety of the ordinary conjunction *wē*- or *û*- "and," which either had a heavier vocalization or altered the accent of the verb; for example, *hālō'khtā wat-tiqṭōl* meant "thou hast gone and killed"; similarly, *tēlēkh wē-qāṭaltā* meant "thou wilt go and kill." In the first the imperfect represented the action as emergent; accordingly, when combined with a conjunction connecting the event introduced by it with a point already reached by the narrative, it represented it as the development of the part

which preceded it; thus, *wat-tiqṭōl* meant "and thou wentest on to kill," while *wē-tiqṭōl* is simply "and thou wilt kill." In the second the perfect *wē-qāṭaltā* meant "so thou hast killed," the possible occurrence of the event being confined to a particular area previously implied or defined, whereas the simple perfect *wē-qāṭaltā* would mean unconditionally "and thou hast killed." The various uses of this construction afford a relief to the monotony of a long string of clauses co-ordinated rather than subordinated to one another. But this idiom began, under Aramaic influence after the exile, to die out, and the simpler constructions, like *hālakhā wē-qāṭaltā*, "thou hast gone and killed," and *tēlēkh wē-tiqṭōl*, "thou shalt go and kill," become a mark of later Hebrew. The participle also in all periods was freely used to eke out the inadequacy of these two tenses. Another device was the "circumstantial clause," whereby a clause introduced by "and" served as a secondary predicate; e.g., the Hebrew said "he found him (and) he ploughing" instead of "he found him ploughing," using the participle and not a finite verb in a parallel, in place of a subordinate, clause.

The material for forming a judgment on Hebrew is itself scanty and inadequate. Even so, the smallness of the vocabulary and the paucity of adverbs, adjectives and abstract nouns are noticeable. The first difficulty was obviated by prepositional phrases, auxiliary verbs and similar devices, the second by apposition or a descriptive genitive case. The lack of abstract nouns, which only became frequent after the exile, was circumvented by the feminine singular or plural adjective; thus *rā'āh* (fem. sing.) stands for "wickedness" and *qāshōth* (fem. plur.), "harsh things," for "harshness." Another feature was the expression of the abstract under a concrete form; thus *kābhēdh*, "was heavy," meant also "was honourable," and from it both *kābhēdh*, "liver" (as the "heavy" organ), and *kābhōdh*, "abundance" and "honour," were both derived. It is, on the contrary, a sign of lateness when an abstract noun like *mōdha*, "acquaintance," designated a concrete person.

Hebrew was less suited for the definite expression of studied thought and the treatment of abstract subjects than for poetry. There was a great lack of particles to express the more subtle connection of ideas; there were few words or inflexions to indicate slight modifications of meaning, although possibly Hebrew, like other Semitic languages, formerly distinguished verbal moods in a way now obscured by the Masoretes. The use of the tenses was largely determined, especially in poetry, by the imagination, which regarded things unaccomplished as accomplished, the past as present and the future as fulfilled. It must, however, be remembered that living Hebrew never had to express abstract ideas; Ecclesiastes, which alone grappled with an abstract subject in plain prose, was composed when Hebrew was already dying out.

In prose, especially of the pre-exilic period, considerable differences of form and style can be detected, due partly to the time and place of composition, partly to the individuality and talent of the authors. Through them especially the various documents woven into the text can be disentangled. Yet the structure and, except in isolated cases, the vocabulary and phraseology, were much the same. The post-exilic literature shows a constantly closer approximation of the language to the cognate Western Aramaic idiom. The process was very gradual; for literary Hebrew was still understood, if not spoken, by the people at least in the 2nd century B.C.; and its extensive use in popular religious literature, partly preserved in the liturgy and elsewhere, proves that it was not entirely forgotten even in the 3rd century A.D. The poetical language employed peculiar words and meanings, forms especially of prepositions and pronominal suffixes, inflexions and constructions; but these distinctions were not so marked as in Greek. Many of them, being found in ordinary use in the cognate languages, notably in Aramaic, were often probably archaisms from the common Semitic vocabulary, surviving in Hebrew only in poetry; for example, the late and poetical *kethem*, "gold," has now been found in Canaanite. In other cases, possibly, Hebrew poets deliberately embellished their language with Aramaisms; for there is evidence that Aramaic was known to educated Hebrews in the latter part of the 8th century B.C. Apart from Arama-

isms, there was a definite poetical vocabulary; for example, *'ōrah* for *derekh*, "way." There was, particularly, a tendency to substitute adjectives for nouns; for example, *lēbhānāh*, "the white one," for *yārēāh*, "moon." The article and *'eth*, the sign of the accusative, were frequently omitted; the relative particle was freely dropped; the shortened imperfect was more widely employed; the governing power of prepositions was extended; the greater scope allowed to the imagination in the use of the tenses frequently obscures the sequence of events to a Western reader; and a forceful brevity of expression was affected. Poetry was accentual and was distinguished from prose by rhythm and parallelism. The poetical instinct was seemingly satisfied by lines of approximately the same length, combined normally into groups of two, three or four lines and constituting verses which marked more distinct pauses in the thought than the separate lines. The line normally consisted of seven or eight syllables, but there was apparently no rule on the subject; when it was longer than seven or eight syllables, a caesura commonly divided it into halves, each of so many beats. The fundamental form of the verse was the two-lined couplet, of which the second either repeated or re-enforced or completed the thought of the first. These couplets exemplified the main principle of Hebrew poetry, the parallelism of two roughly equal clauses, of which the second answered or completed the first. This might be synonymous, in which the second repeated the thought of the first line; antithetic, in which the thought of the one was contrasted with that of the other line; constructive, in which the second supplemented the thought of the first line; or climactic, in which the second line took up words from and completed the first line, which was incomplete. The poets sometimes grouped their verses into stanzas, marking the close by a refrain; but the number of verses in a stanza was never, according to the Masoretic text, more than approximately uniform in any poem. The *qināh*, "elegiac rhythm," in which the line consisted of two members, the first containing one beat more than the second, exhibited the clearest scheme. Rhyme was as accidental as in classical Greek or Latin poetry; but both rhyme and quantitative metre were introduced, after the Arabic model, by mediaeval poets, who combined them with the vocabulary and idiom, as far as possible, of the earlier language.

At first foreign words were rare. There are occasional Egyptian words like *'āhū* (Eg. *'hw*), "reeds," and *geseth* (Eg. *gsty*), "ink-horn," and Assyrian words like *sē'ōn* (Ass. *shēnu*), "boot," learnt probably from invading soldiers. The Babylonian *pāru*, "lot," was introduced in the plural *pūrim*, "lots," to designate a post-exilic feast. Persian words also, like *dāth* (Pers. *dāta*), "law," came in. But late Aramaic, as closely resembling Hebrew, exerted, especially after the exile, an ever-increasing influence. Aramaic words and forms appeared: the Hebr. *-āh* began to be displaced by the Aram. *-ā* in feminine nouns, and the Hebr. *dābhār* to yield to the Aram. *millēthā* in the Hebraized form *millāh*, "word," which even has two plur. forms (Hebr. *millim* and Aram. *millin*) in the same book. Hebrew words were sometimes Aramaized in form, as when the Hebr. *nāṣar* became *nātar* like the Aram. *nētar*, "kept," or in meaning, as when the Hebr. *ṭa'am*, "taste," came to mean "decree" like the Aram. *ṭe'em* (cf. Ass. *ṭemu*), "command." Abstract nouns in *-ūth*, like *malakhūth*, "kingdom," became common and are even formed from infinitives, like *hashmā'ūth*, "proclaiming," on the Aramaic model. The pronominal suffixes were weakened, so that such an Aramaism as *karmī shellī*, "my vineyard which is to me," tended to oust the simple Hebrew *karmī*, "my vineyard." The classical *'āsher*, "who, which," lingered chiefly in combinations based on the old literary language, while the dialectical *she-* on the analogy of the Aramaic *dē-* displaced it in those derived from the popular Aramaic.

This post-exilic Hebrew showed also great simplicity and uniformity of style, again largely due to Aramaic influence. For some centuries the Jews must have been bilingual, still understanding Hebrew but speaking Aramaic, the official language of the western provinces of the Persian empire; by the time of Christ, however, Aramaic versions of the Scriptures, called *targūmim*, were becoming necessary. Meanwhile Hebrew, without dying out, became gradually a *lēshōn hākhāmim*, "language of scholars," as

indeed it had begun to be in the later Scriptures. Roughly from 100 B.C. to A.D. 100 little is known of it; but after that it was greatly developed in the *Mishnāh* (c. A.D. 200). It was still a living language, though mainly confined to the schools and clearly distinct from Biblical Hebrew. In the Scriptures the range of subjects was limited; in the *Mishnāh* it was much extended. Matters of daily life were minutely discussed and words and phrases were adopted from the earlier and presumably popular speech; further, since the language was no longer in the same sense familiar, greater definiteness of expression was required in the written style.

The first alteration noticeable was the confusion of consonants, especially of the gutturals, which classical Hebrew had kept distinct. This change shows that the writers were accustomed to the daily use of Aramaic. Greek and Latin words, relating to the affairs of ordinary life, for whose writing the rules of classical orthography were violated, crept in. For example, biblical Hebrew almost universally required that initial *w* should become *y*, as in *yeledh* for the very rare *wālādh* (cf. Arab. *waladu*), "boy"; but barbarisms like *wēthas* (Gr. *εὐθύς*), "at once," and *wilōn* (Lat. *velum*), "curtain," were admitted, and henceforward the objection to forms like *wa'ad* (B. Hebr. *mō'ed*), "meeting," was less strongly felt.

Biblical Hebrew, having lost the case-endings, used *'eth* to mark the definite accusative case; but Mishnaic Hebrew employed *'eth* not only to introduce the direct object, but also to serve alone as a definite article or, with a pronominal suffix, as a pronoun meaning "that" or "the same." Fresh pronouns, too, were coined by combining those already existing into compound forms or by adopting or adapting many from Aramaic. New adverbs, prepositions and conjunctions, especially subordinating conjunctions, were freely invented or imported from Aramaic.

The vocabulary was greatly enriched. Many biblical words remained, although some nouns changed their meaning; thus B. Hebr. *gōlem*, "embryo," became the M. Hebr. *gōlem*, "lump," "mass." New nouns were coined from biblical roots; so beside the B. Hebr. *hemedh*, "desire," there arose the M. Hebr. *himmūdh*, "desire," from *hāmādh*, "desired." Especially noticeable are the numerous quadriliteral and quinqueliteral formations, which were rare in biblical Hebrew. Lastly, good Hebrew words appear which, though unknown in the Scriptures, must have belonged to the old spoken language. Beside the numerous Greek and Latin words, a few Persian (or Arabic) words crept in. These generally retained their original appearance, while one Greek word passed over in the genitive case (M. Hebr. *'andri'antōs* = Gr. *ἀνδριάντος*, from *ἀνδράς*, "statue"); only rarely were they furnished with Hebrew terminations. The inflection of nouns remained unchanged; but many masculine nouns acquired feminine endings, and the Aramaic masculine plural ending *-in* was much commoner than the Hebrew *-im*, although the Hebrew feminine ending *-ōth* was regularly retained. Finally, the "construct state," whereby a noun governing a genitive case undergoes phonetic modification, survived sporadically; but a periphrasis with *shel-* ("which is to"), "of," the preposition *lē-*, "to," or the Aram. *dē-*, "of," tended to displace it. This relative particle *she-*, which belonged to dialect in biblical Hebrew, completely ousted the classical *'āsher*, "who," "which," from Mishnaic Hebrew.

The supply of verbs also was much enlarged. Foreign verbs, being ill suited to the Hebrew conjugations, were rarely adopted, but a few were formed from nouns; e.g., *sāphagh*, "absorbed," from *sēphōgh* (Gr. *σπόγγος*), "sponge." The imperatives *kīrī* (written כִּירִי = Gr. *χαίρε*) "hail!" and *wīwī* (written וִוִּי = Lat. *vive*), "live," are exceptions. But Aramaic verbs, which closely resembled Hebrew verbs, were readily assimilated, while some classical verbs received new meanings; e.g., *zākhāh*, "was innocent," acquired the sense of "succeeded." Others, used originally in the simple theme, afterwards affected a derived theme. Many roots known only from derived nouns or quite unknown in biblical Hebrew, became general. Additional verbs were coined from derivative nouns; e.g., *tāram*, "exact the heave-offering" (B. Hebr. *tērūmāh*) and *mishkēn*, "took a pledge" (M. Hebr. *mishkōn*), "pledge." Quadriliteral and quinqueliteral verbs, rare in biblical

Hebrew, became common. The conjugations remained substantially unchanged; but the third person feminine singular took *-eth* (*-ath*) in place of *-āh* in the reflexive theme. Certain weak verbs also deviated slightly from the classical norm.

The themes underwent some slight changes. Canaanite had marked the active and passive voices by modifying the vowel (cf. *laqāhu*, "they took," but *laqīhu*, "they were taken") and biblical Hebrew sporadically preserved this difference between transitive and intransitive verbs (cf. between *zākhār*, "remembered," and *shākhēn*, "dwelt"). Of an internally formed passive the only certain survival is the participle; e.g., *zākhūr*, "remembered." Other traces are probably concealed under certain forms which the Masoretes obscured. In its place, biblical Hebrew used the passives of the derived themes. These (according to the paradigm of *pa'al*, "did") were the reflexive *niph'al*, the intensive and causative *pi'el*, the causative *hiph'il* and the reflexive *hitpa'el*. The *niph'al* easily acquired a passive force; the *pa'al*, less often the *hoph'al* (the passives of the *pi'el* and *hiph'il* respectively), were often also so used. But in later Hebrew the *niph'al* and even more the *hoph'al* tended, owing to ambiguity in their meanings, to become less frequent, whereas the *hitpa'el* became extremely common, both with a reflexive and less often with a passive force. Simultaneously a new form, the *nithpa'el*, of which biblical Hebrew offers but three examples, became extremely common with a purely passive sense. Of the active themes the *pi'el* served extensively in forming new verbs from nouns and replacing the simple theme customary with many classical verbs and the *hiph'il* somewhat extended its usage. An Aramaic causative theme, formed by prefixing *shā-* or *sa-*, instead of *hi-*, was not unknown.

The old tense-system was inadequate, and the loss of "wāw-consecutive" made it even more inadequate. The perfect expressed only completed action in past time; and more than the old imperfect was required for incomplete action in the past, present and future. Various periphrases were therefore devised. Past incomplete action was denoted by the verb *hāyāh*, "was," with the participle; e.g., *hāyāh 'ōmēr*, "he was saying," was distinguished from *'āmar*, "he said," while the imperfect *yōmēr* was left with a jussive force, meaning "he should say." The present participle alone connoted present time; but a pronominal subject, being no longer implicit or explicit in inflection, had to be expressed; e.g., *'ānī 'ōmēr* or *'ōmēr 'ānī*, "I say." This gave rise to a completely new Aramaizing tense, formed by combining the participle with the following pronouns; for example, *'ōmērānī*, "I say." The future was expressed by the adjective *'āthīdh*, "ready," or the noun *sōph*, "end," with a pronominal suffix referring to the subject, followed by the infinitive introduced by *lē-*, "to"; e.g., *'ānī 'āthīdh lōmar*, "I am ready to say," or *sōphī lōmar*, "my end (is) to say," viz., "I will say"; or by *lē-* and the infinitive alone, as sometimes in biblical Hebrew, denoting rather what ought than what will happen; e.g., *'ānī lōmar*, "I am to say." To express obligation, for which biblical Hebrew had no regular phrases, Mishnaic Hebrew used the adjective *šārikkh*, "needed," with the infinitive; e.g., *'ānī šārikkh lōmar*, "I must say."

Thus Hebrew, with its archaic stiffness, lost also the austere beauty and stately dignity of its prime. In exchange it acquired simplicity and flexibility and adapted itself better to the needs of every day, though the disappearance of much that is characteristically Hebrew before the invasion of Aramaic cannot but be regretted. Hebrew still lives as the language of Jewish scholars, though coloured in varying degrees with the writer's own speech, whether Persian, Arabic, French, German or whatever it may be. The structure is Hebrew; the vocabulary is often very foreign. This must be increasingly so; for ancient Hebrew is ill adapted to modern needs. As mediaeval grammar and philosophy demanded Arabic terms, so modern science requires European terms, often borrowed through Arabic. (See YIDDISH.) (G. R. D.)

HEBREW LITERATURE. "Hebrew Literature" denotes works written in the Hebrew language. Frequently, however, the expression is used as synonymous with Jewish literature, including all works written by Jews in Hebrew characters, whether the language be Aramaic, Arabic or even some vernacular not

related to Hebrew.

Old Testament Scriptures.—The literature begins with the earliest portions contained in the Old Testament. There were no doubt in the earliest times popular songs orally transmitted and perhaps books of annals and laws, but except in so far as remnants of them are embedded in the biblical books, they have entirely disappeared. The traditional view that Moses was the author of the Pentateuch in its present form, would make this the earliest monument of Hebrew literature. Modern inquiry, however, has arrived at other conclusions affecting not only the Pentateuch but the other Old Testament books as well (see BIBLE: *Old Testament*).

Apocryphal Literature.—It is not to be supposed that all the contents of the Old Testament were immediately accepted as sacred, or that they were ever all regarded as being on the same level. The Torah, the Law delivered to Moses, held among the Jews of the 4th century B.C. as it holds now, a pre-eminent position. The inclusion of other books in the Canon was gradual, and was effected only after centuries of debate. The Jews have always been, however, an intensely literary people, and the books ultimately accepted as canonical were only a selection from the literature in existence at the beginning of the Christian era. The rejected books receiving little attention have mostly either been altogether lost or have survived only in translations, as in the case of the Apocrypha. Hence from the composition of the latest canonical books to the redaction of the Mishnah (see below) in the 2nd century A.D., the remains of Hebrew literature are very scanty. There was formed during this period a large body of exegetical and legal material, for the most part orally transmitted, which only received its literary form much later.

Halakhah.—Not only was translation, and therefore exegesis, cultivated, but even more the amplification of the Law. According to Jewish teaching (e.g., Abboth i. 1) Moses received on Mount Sinai not only the written Law as set down in the Pentateuch, but also the Oral Law, which was transmitted to the 70 elders and through them by a "chain of tradition" to succeeding ages. The application of this oral law is called *Halakhah*, the rules by which a man's daily "walk" is regulated. The halakhah was by no means inferior in prestige to the written Law. Indeed some even ventured to ascribe a higher value to it, since it comes into closer relation with the details of everyday life. It was not independent of the written Law, still less could it be in opposition to it. Rather it was implicitly contained therein, and the duty of the teacher was to show this. It was therefore important that the chain of tradition should be continuous and trustworthy. The line is traced through biblical teachers to Ezra, the first of the Sopherim or scribes, who handed on the charge to the "men of the Great Synagogue," a much-discussed term for a body or succession of teachers inaugurated by Ezra. The last member of it, Simon the Just (either Simon I., who died about 300 B.C., or Simon II., who died about 200 B.C.), was the first of the next series, called Elders, represented in the tradition by *pairs* of teachers, ending with Hillel and Shammai about the beginning of the Christian era. Their pupils form the starting-point of the next series, the Tannaim (from Aram. *tenā*, to teach), who occupy the first two centuries A.D.

Mishnah.—By this time the collection of halakhic material had become very large and various, and after several attempts had been made to reduce it to uniformity, a code of oral tradition—the Mishnah—was finally drawn up in the 2nd century by Judah ha-Nasi, called Rabbi *par excellence*. The name Mishnah is derived from the Hebrew *shanah*, corresponding to the Aramaic *tenā*, and therefore a suitable name for a tannaitic work, meaning the *repetition* or *teaching* of the oral law. Its language differs in many respects from that of the Old Testament (see HEBREW LANGUAGE). It is divided into six "orders," according to subject, and each order is subdivided into treatises. In making his selection of halakhōth, Rabbi used the earlier compilations, which are quoted as "words of Rabbi 'Aqiba" or of Rabbi Me'ir, but rejected much which was afterwards collected under the title of *Tosefta* (*addition*) and *Baraita* (*outside the Mishnah*).

Midrash.—Traditional teaching was, however, not confined to

halakhah. Since the teachers endeavoured to show the connexion of practical rules with the written Law, there arose the Midrash, *exposition*, from *darash* to "investigate" a scriptural passage. Of the halakhic Midrash we possess that on Exodus, called *Mekhilta*, that on Leviticus, called *Sifra*, and that on Numbers and Deuteronomy, called *Sifre*. These were drawn up in the period of the Amoraim, the order of teachers who succeeded the Tannaim, from the close of the Mishnah to about A.D. 500. The term Midrash, however, more commonly implies *agada*, i.e., the homiletical exposition of the text, with illustrations designed to make it more attractive to the readers or hearers. It began with the Sopherim and was most developed among the Tannaim and Amoraim. As the halakhoth were collected and edited in the Mishnah, so the agadic material was compiled and arranged in the Midrashim. Most of these collections form a sort of continuous commentary on the books of the Bible, Midrash, *Rabbōth* so called in order to distinguish them from preceding smaller collections. *Bereshith Rabba*, on Genesis, and *Ekhah Rabbati*, on Lamentations, were probably edited in the 7th century. Of the same character and of about the same date are the *Pesiqta*, on the lessons for Sabbaths and feast-days, and *Wayyiqra R.* on Leviticus. A century perhaps later is the *Tanhūma*, on the sections of the Pentateuch, and later still the *Pesiqta Rabbati*, *Shemōth R.* (on Exodus), *Bemidbar R.* (on Numbers), *Debharim R.* (on Deuteronomy). There are also Midrashim on Canticles, Ruth, Ecclesiastes, Esther and the Psalms, belonging to this later period, the *Pirqe R. Eliezer*, of the 8th or 9th century, a sort of history of creation and of the patriarchs, and the *Tanna debē Eliyahū* (an ethical work of the 10th century but containing much that is old), besides a large number of minor compositions. (See especially J. D. Eisenstein's *Ozar Midrashim* [New York, 1915], for these lesser midrashim.) In general, these performed very much the same function as the lives of saints in the early and mediaeval church. Very important for the study of Midrashic literature are the *Yalqūt* (*gleaning*) *Shim'oni*, on the whole Bible, the *Yalqūt Mekhiri*, on the Prophets, Psalms, Proverbs and Job, and the *Midrash ha-gadhōl*, all of which are of uncertain but late date and preserve earlier material. That on Genesis was edited for the first time by Schechter (1902), and that on Exodus by D. Hoffmann (1913). The last, which is preserved in MSS. from Yemen, is especially valuable as representing an independent tradition.

THE TALMUD

Meanwhile, if agadic exegesis was popular in the centuries following the redaction of the Mishnah, the study of halakhah was by no means neglected. As the discussion of the Law led up to the compilation of the Mishnah, so the Mishnah itself became in turn the subject of further discussion. The material thus accumulated, both halakhic and agadic, forming a commentary on and amplification of the Mishnah, was eventually written down under the name of *Gemara* (from *gemar*, to learn completely), the two together are commonly spoken of as the *Talmud* (properly "*instruction*"). There are two distinct works to which the title *Talmud* is applied. One contains the oral traditions which had grown up in the Palestinian Schools and the other those of the schools of Babylonia. Both were due to the Amoraim and were completed by about A.D. 500, though the date at which they were actually committed to writing is very uncertain. Both are arranged according to the six orders of the Mishnah, but the discussion of the Mishnaic text often wanders off into widely different topics. Neither is altogether complete. In the Palestinian *Talmud* (*Yerushalmi*) the *gemara* of the 5th order (*Qodashim*) and of nearly all the 6th (*Tohorōth*) is missing, besides smaller parts. In the Babylonian *Talmud* (*Babli*) there is no *gemara* to the smaller tractates of Order 1, and to parts of ii., iv., v., vi. The language of both is in the main the Aramaic vernacular (western Aramaic in *Yerushalmi*, eastern in *Babli*), but early halakhic traditions (e.g., of Tannaitic origin) are given in their original form, and the discussion of them is usually also in Hebrew. *Babli* is not only greater in bulk than *Yerushalmi*, but has also received far greater attention, so that the name *Talmud* alone is often used for it. As being a constant object of study numerous commentaries

have been written on the *Talmud* from the earliest times till the present. The most important of them for the understanding of the *gemara* (*Babli*) is that of Rashi (Solomon ben Isaac, d. 1104) with the *Tōsafōth* (*additions*, not to be confused with the *Tosefta*) chiefly by the French school of rabbis following Rashi. Since the introduction of printing, the *Talmud* is always cited by the number of the leaf in the first edition (Venice, 1520, etc.), to which all subsequent editions conform. In order to facilitate the practical study of the *Talmud*, it was natural that abridgements of it should be made. Two of these may be mentioned: that by Isaac Alfasi (i.e., of Fez) in the 11th century, often cited as *Rif*; and that by Asher ben Yehiel (d. 1328) of Toledo, usually cited as *Rabbenū Asher* (*Rosh*). The object of both was to collect all halakhōth having a practical importance, omitting all those which no longer possess more than an academic interest, and excluding the discussions on them and all *agada*. Both add notes and explanations of their own, and both have in turn formed the text of commentaries.

With the *Talmud*, the anonymous period of Hebrew literature may be considered to end. Henceforward important works are produced not by schools but by particular teachers, who, however, no doubt often represent the opinions of a school.

The Geonim.—The order of the Amoraim, which ended with the close of the *Talmud* (A.D. 500), was succeeded by that of the Sabōraim, who merely continued and explained the work of their predecessors, and these again were followed by the Geonim, the heads of the schools of Sura and Pumbeditha in Babylonia. The office of Gaon lasted for something over 400 years, beginning about A.D. 600, and varied in power according to the ability of its holders. Individual Geonim produced valuable works (of which later), but what is perhaps most important from the point of view of the development of Judaism is the literature of their Responsa or answers to questions, chiefly on halakhic matters, addressed to them from various countries. Some of these were actual decisions of particular Geonim; others were an official summary of the discussion of the subject by the members of the School. They begin with Mar Rab Sheshna (7th century) and continue to Hai Gaon, who died in 1038, and are full of historical and literary interest. (See the edition of them in Harkavy, *Studien*, iv. [Berlin, 1885].) The *She'iltōth* (*questions*) of Rab Ahai (8th century) also belong probably to the school of Pumbeditha, though their author was not Gaon. Besides the Responsa, but closely related to them, we have the lesser Halakhōth of Yehūdai Gaon of Sura (8th century) and the great Halakhōth of Simeon Qayyara of Sura (not Gaon) in the 9th century. In a different department there is the first *Talmud* lexicon (*'Arūkh*) now lost, by Zemah ben Paltoi, Gaon of Pumbeditha in the 9th century. All these writers, however, are entirely eclipsed by the commanding personality of the most famous of the Geonim, Seadiah ben Joseph (q.v.) of Sura, often called al-Fayyūmī (of the Fayum in Egypt), one of the greatest representatives of Jewish learning of all times, who died in 942. The last three holders of the office were also distinguished. Sherira of Pumbeditha (d. 998) was the author of the famous "Letter" (in the form of a Responsum to a question addressed to him by residents in Kairawan), an historical document of the highest value and the foundation of our knowledge of the history of tradition. His son Hai, last Gaon of Pumbeditha (d. 1038), a man of wide learning, wrote (partly in Arabic) not only numerous Responsa, but also treatises on law, commentaries on the Mishnah and the Bible, a lexicon called in Arabic *al-Ḥāwī*, and poems such as the *Mūsar Haskel*, but most of them are now lost or known only from translations or quotations. Though his teaching was largely directed against superstition, he seems to have been inclined to mysticism, and perhaps for this reason various kabbalistic works were ascribed to him in later times. His father-in-law Samuel ben Ḥophni, last Gaon of Sura (d. 1034), was a voluminous writer on law, translated the Pentateuch into Arabic, commented on much of the Bible, and composed an Arabic introduction to the *Talmud*, of which the existing Hebrew introduction (by Samuel the Nagid) is perhaps a translation. Most of the works of this author are now lost.

THE QARAITES AND MEDIAEVAL SCHOLARSHIP

In the Geonic period there came into prominence the sect of the Qaraites (*Benē miqrā*, "followers of the Scripture," the protestants of Judaism) who rejected rabbinical authority, basing their doctrine and practice exclusively on the Bible. The sect was founded by 'Anan in the 8th century, and, after many vicissitudes, still exists. Their literature is largely polemical and to a great extent deals with grammar and exegesis. Of their first important authors, Benjamin al-Nehawendi and Daniel al-Qūmisī (both in the 9th century), little is preserved. In the 10th century Jacob al-Qirqisānī wrote his *Kitāb al-anwār*, on law, Solomon ben Yeruham (against Seadiah) and Yefet ben 'Ali wrote exegetical works; in the 11th century Abū'l-faraj Furqān, exegesis, and Yūsuf al-Baṣīr against Samuel ben Hophni. Most of these wrote in Arabic. In the 12th century and in S. Europe, Judah Hadassi composed his *Eshkol ha-Kōpher*, a great theological compendium in the form of a commentary on the Decalogue. Other writers are Aaron (the elder) ben Joseph, 13th century, who wrote the commentary *Sepher ha-mibhār*; Aaron (the younger) of Nicomedia (14th century), author of *Ez Hayyim*, on philosophy, *Gan 'Eden*, on law, and the commentary *Kether Tōrah*; in the 15th century Elijah Bashyazī, on law (*Addereth Eliyahū*), and Caleb Efen-dipoulo, poet and theologian; in the 16th century Moses Bashyazī, theologian. From the 12th century onward the sect gradually declined, being ultimately restricted mainly to the Crimea and Lithuania, learning disappeared and their literature became merely popular and of little interest. Much of it in later times was written in a curious Tatar dialect. Mention need only be made further of Isaac of Troki, whose anti-Christian polemic *Hizzūq Emūnah* (1593) was translated into English by Moses Mocatta under the title of *Faith Strengthened* (1851); Solomon of Troki, whose *Appiryōn*, an account of Qaraism, was written at the request of Pufendorf (about 1700); and Abraham Firkovich, who, in spite of his impostures, did much for the literature of his people about the middle of the 19th century. (See also QARAITES.)

To return to the period of the Geonim. While the schools of Babylonia were flourishing as the religious head of Judaism, the West, and especially Spain under Moorish rule, was becoming the home of Jewish scholarship. On the breaking up of the schools many of the fugitives fled to the West and helped to promote rabbinical learning there. The communities of Fez, Kairawan and N. Africa were in close relation with those of Spain, and as early as the beginning of the 9th century Judah ben Quraish of Tahort had composed his *Risālah* (letter) to the Jews of Fez on grammatical subjects from a comparative point of view, and a dictionary now lost. His work was used in the 10th century by Menahem ben Sarūq, of Cordova, in his *Mahbereth* (dictionary). Menahem's system of bi-literal and uni-literal roots was violently attacked by Dūnash ibn Labrāt, and as violently defended by the author's pupils. Among these was Judah Hayyūj of Cordova, the father of modern Hebrew grammar, who first established the principle of tri-literal roots. His system was adopted by Abū'l-walid ibn Jannāh, of Saragossa (died early in the 11th century), in his lexicon (*Kitāb al-uṣūl*, in Arabic) and other works. In Italy appeared the invaluable Talmud-lexicon (*Arūkh*) by Nathan b. Yehiel, of Rome (d. 1106), who was indirectly indebted to Babylonian teaching. He does not strictly follow the system of Hayyūj. Other works of a different kind also originated in Italy about this time: the very popular history of the Jews, called *Josippon* (probably of the 10th or even 9th century), ascribed to Joseph ben Gōriōn (Gorionides); two different texts of it exist: (1) in the ed. pr. (Mantua, 1476); (2) ed. by Seb. Münster (Basel, 1541); there is also an early Arabic recension, but its relation to the Hebrew and to the Arabic 2 Maccabees is still obscure; see *J.Q.R.*, xi. 355 sqq. The Hebrew text was edited with a Latin translation by Breithaupt (Gotha, 1707); the medical treatises of Shabbethai Donnolo (10th century) and his commentary on the *Sepher Yeẓirah*, the anonymous and earliest Hebrew kabbalistic work ascribed to the patriarch Abraham. In North Africa, probably in the 9th century, appeared the book known under the name of *Eldad ha-Danī*, giving an account of the ten tribes, from which much mediaeval legend

was derived; on the various recensions of the text see D. H. Müller in the *Denkschriften* of the Vienna Academy (*Phil.-hist. Cl.*, xli. 1, p. 41) and Epstein's ed. (Pressburg, 1891); in Kairawan the medical and philosophical treatises of Isaac Israeli, who died in 932.

Exegesis.—The aim of the grammatical studies of the Spanish school was ultimately exegesis. This had already been cultivated in the East. In the 9th century Hīvi of Balkh wrote a rationalistic treatise on difficulties in the Bible, which was refuted by Seadiah. A fragment of such a work, probably emanating from the school of Hīvi was found by Schechter and published in *J.Q.R.*, xiii. 345 sqq. A fragment of Seadiah's polemic against Hīvi was edited with an English translation, introduction and notes by Israel Davidson (New York, 1915). The commentaries of the Geonim have been mentioned above. The impulse to similar work in the West came also from Babylonia. In the 10th century Hushiel, one of four prisoners, perhaps from Babylonia, though that is doubtful, was ransomed and settled at Kairawan, where he acquired great reputation as a Talmudist. His son Hananeel (d. 1050) wrote a commentary on (probably all) the Talmud, and one now lost on the Pentateuch. Hananeel's contemporary Nissim ben Jacob, of Kairawan, who corresponded with Hai Gaōn of Pumbeditha as well as with Samuel the Nagid in Spain, likewise wrote on the Talmud, and is probably the author of a collection of *Ma'asiyyōth* or edifying stories, besides works now lost. The activity in North Africa reacted on Spain. There the most prominent figure was that of Samuel ibn Nagdela (or Nagrela), generally known as Samuel the Nagid or head of the Jewish settlement, who died in 1055. As vizier to the Moorish king at Granada, he was not only a patron of learning, but himself a man of wide knowledge and a considerable author. Some of his poems and an Introduction to the Talmud are extant. In grammar he followed Hayyūj, whose pupil he was. Among others he was the patron of Solomon ibn Gabirol (*q.v.*), the poet and philosopher. To this period belong Hāfz al-Qūṭī (the Goth?) who made a version of the Psalms in Arabic rhyme, and Baḥya (more correctly Behai) ibn Paqūda, dayyan at Saragossa, whose Arabic ethical treatise has always had great popularity among the Jews in its Hebrew translation, *Hōbhōth ha-lebhabhōth*. He also composed liturgical poems. At the end of the 11th century Judah ibn Bal'am wrote grammatical works and commentaries (on the Pentateuch, Isaiah, etc.) in Arabic; the liturgist Isaac Gayyath (d. in 1089 at Cordova) wrote on ritual. Moses Gikatilla (11th century), grammarian and exegetist, was the first to suggest that the second half of the Book of Isaiah was the work of a prophet near the end of the Babylonian exile.

Rashi.—The French school of the 11th century was hardly less important. Gershom ben Judah, the "Light of the Exile" (d. in 1040 at Mainz), a famous Talmudist and commentator, his pupil, Jacob ben Yaqar, and Moses ha-Darshan of Narbonne, were the forerunners of the greatest of all Jewish commentators, Solomon ben Isaac (Rashi), who died at Troyes in 1105. Rashi was a pupil of Jacob ben Yaqar, and studied at Worms and Mainz. Unlike his contemporaries in Spain, he seems to have confined himself wholly to Jewish learning, and to have known nothing of Arabic or other languages except his native French. Yet no commentator is more valuable or indeed more voluminous, and for the study of the Talmud he is indispensable. He commented on all the Bible and on nearly all the Talmud, has been himself the text of several super-commentaries, and has exerted much influence on Christian exegesis. Closely connected with Rashi, or of his school, are Joseph Qara, of Troyes (d. about 1130), the commentator, and his teacher Menahem ben Hēlbō, Jacob ben Me'ir, called Rabbenū Tam (d. 1171), the most important of the Tosaphists (*v. sup.*), and later in the 12th century the liberal and rationalizing Joseph Bekhōr Shōr, and Samuel ben Me'ir (d. about 1174) of Ramerupt, commentator and Talmudist.

In the 12th and 13th centuries literature maintained a high level in Spain. Abraham bar Hiyya, known to Christian scholars as Abraham Judaeus (d. about 1136), was a mathematician, astronomer and philosopher much studied in the middle ages.

Moses ibn Ezra, of Granada (d. about 1140), wrote in Arabic a philosophical work based on Greek and Arabic as well as Jewish authorities, known by the name of the Hebrew translation as *Arūgath ha-bosem*, and the *Kitāb al-Maḥādarak*, of great value for literary history. He is even better known as a poet, for his *Diwān* and the *ʿAnaq*, and as a hymn-writer. His relative, Abraham ibn Ezra, was still more distinguished. He was born at Toledo, spent most of his life in travel, wandering even to England and to the East, and died in 1167. Yet he contrived to write his great commentary on the Pentateuch and other books of the Bible, treatises on philosophy (as the *Yesōdh mōra*), astronomy, mathematics, grammar (translation of Ḥayyūj), besides a *Diwān*. The man, however, who shares with Ibn Gabirol the first place in Jewish poetry is Judah Ha-levi, of Toledo, who died in Jerusalem about 1140. His poems, both secular and religious, contained in his *Diwān* and scattered in the liturgy, are all in Hebrew, though he employed Arabic metres. In Arabic he wrote his philosophical work, called in the Hebrew translation *Sepher ha-Kūzārī*, a defence of revelation as against non-Jewish philosophy and Qaraite doctrine. It shows considerable knowledge of Greek and Arabic thought (Avicenna). Joseph ibn Migāsh (d. 1141 at Lucena), a friend of Judah Ha-levi and of Moses ibn Ezra, wrote Responsa and novelae on parts of the Talmud. In another sphere mention must be made of the travelers Benjamin of Tudela (d. after 1173), whose *Massa'oth* are of great value for the history and geography of his time, and (though not belonging to Spain) Pethahiah of Regensburg (d. about 1190), who wrote short notes of his journeys. Abraham ben David, of Toledo (d. about 1180), in philosophy an Aristotelian (through Avicenna) and the precursor of Maimonides, is known for his *Sepher ha-qabbalah*, a polemic against Karaism, but valuable for the history of tradition and for his *Emunah Ramah*, a philosophical work.

Maimonides.—The greatest of all mediaeval Jewish scholars was Moses ben Maimōn (Rambam), called *Maimonides*. He was born at Cordova in 1135, fled with his parents from persecution in 1148, settled at Fez in 1160, passing there for a Muslim, fled again to Jerusalem in 1165, and finally went to Cairo where he died in 1204. He was distinguished in his profession as a physician, and wrote a number of medical works in Arabic (including a commentary on the aphorisms of Hippocrates), all of which were translated into Hebrew, and most of them into Latin, becoming the text-books of Europe in the succeeding centuries. But his fame rests mainly on his theological works. Passing over the less important, these are the *Mōreh Nebhūkhīm* (the Hebrew translation of the Arabic original), an endeavour to show philosophically the reasonableness of the faith, parts of which, translated into Latin, were studied by the Christian schoolmen, and the *Mishneh Tōrah*, also called *Yad haḥazakah* (יָד = 14, the number of the parts), a classified compendium of the Law, written in Hebrew and early translated into Arabic. The latter of these, though generally accepted in the East, was much opposed in the West, especially at the time by Abraham ben David of Posquières (d. 1198). Maimonides also wrote an Arabic commentary on the Mishnah, soon afterwards translated into Hebrew, commentaries on parts of the Talmud (now lost), and a treatise on Logic. His breadth of view and his Aristotelianism were a stumbling-block to the orthodox, and subsequent teachers may be mostly classified as Maimonists or anti-Maimonists. Even his friend Joseph ibn ʿAqnīn (d. 1226), author of a philosophical treatise in Arabic and of a commentary on the Song of Solomon, found so much difficulty in the new views that the *Mōreh Nebhūkhīm* was written in order to convince him. Maimonides's son Abraham (d. 1234), also a great Talmudist, wrote in Arabic *Ma'aseh Yerushalmī*, on oaths, and *Kitāb al-Kifāyah*, theology. His grandson David was also an author.

A very different person was Moses ben Naḥman (Ramban) or Nahmanides (b. at Gerona 1194, d. in Palestine about 1270), who was as conservative as Maimonides was liberal. Much of his life was spent in controversy, not only with Christians (in 1293 before the king of Aragon), but also with his own people and on the views of the time. His greatest work is the commentary

on the Pentateuch in opposition to Maimonides and Ibn Ezra. He had a strong inclination to mysticism, but whether certain kabbalistic works are rightly attributed to him is doubtful. It is, however, not a mere coincidence that the two great kabbalistic text-books, the *Bahir* and the *Zohar* (both meaning "brightness"), appear first in the 13th century. If not due to his teaching they are at least in sympathy with it. The *Bahir*, a sort of outline of the *Zohar*, and traditionally ascribed to Nehunya (1st century), is believed by some to be the work of Isaac the Blind ben Abraham of Posquières (d. early in the 13th century), the founder of the modern Kabbalah and the author of the names for the 10 Sephīrōth. The *Zohar*, supposed to be by Simeon ben Yoḥai (2nd century), is now generally attributed to Moses of Leon (d. 1305), who, however, drew his material in part from earlier written or traditional sources, such as the *Sepher Yeẓirah*. At any rate the work was immediately accepted by the Kabbalists, and has formed the basis of all subsequent study of the subject. Put into the form of a commentary on the Pentateuch, it is really an exposition of the kabbalistic view of the universe showing considerable acquaintance with the natural science of the time. A pupil, though not a follower of Nahmanides, was Solomon ibn Adreth (not Addereth), of Barcelona (d. 1310), a prolific writer of Talmudic and polemical works (against the Kabbalists and Mohammedans) as well as of responsa. He was opposed by Abraham Abulafia (d. about 1291) and his pupil Joseph Gikatilla (d. about 1305), the author of numerous kabbalistic works. Solomon's pupil Bahya ben Asher, of Saragossa (d. 1340) was the author of a very popular commentary on the Pentateuch and of religious discourses entitled *Kad ha-qemah*, in both of which, unlike his teacher, he made large use of the Kabbalah. Other studies, however, were not neglected. In the first half of the 13th century, Abraham ibn Ḥasdai, a vigorous supporter of Maimonides, translated (or adapted) a large number of philosophical works from Arabic, among them being the *Sepher ha-tappuah*, based on Aristotle's *de Anima*, and the *Mōzenē Zedeq* of Ghazzali on moral philosophy, of both of which the originals are lost. Another Maimonist was Shem Tōbh ben Joseph Falaquera (d. after 1290), philosopher (following Averroes), poet and author of a commentary on the *Mōreh*.

A curious mixture of mysticism and Aristotelianism is seen in Isaac Aboab (about 1300), whose *Menorath ha-Ma'or*, a collection of agadōth, attained great popularity and has been frequently printed and translated. Somewhat earlier in the 13th century lived Judah al-Ḥarizī, who belongs in spirit to the time of Ibn Gabirol and Judah ha-levi. He wrote numerous translations of Galen, Aristotle, Ḥarīrī, Ḥunain ben Isaac and Maimonides, as well as several original works, a *Sepher ʿAnaq* in imitation of Moses ben Ezra, and treatises on grammar and medicine (*Rephū-ath geviyyah*), but he is best known for his *Taḥkemōnī*, a diwan in the style of Ḥarīrī's *Maqāmāt*.

EFFECTS OF JEWISH LITERARY ACTIVITY

Meanwhile the literary activity of the Jews in Spain had its effect on those of France. The fact that many of the most important works were written in Arabic, the vernacular of the Spanish Jews under the Moors, which was not understood in France, gave rise to a number of translations into Hebrew, chiefly by the family of Ibn Tibbōn (or Tabbōn). The first of them, Judah ibn Tibbōn, translated works of Bahya ibn Paqudah, Judah ha-levi, Seadiah, Abū'lwalid and Ibn Gabirol, besides writing works of his own. He was a native of Granada, but migrated to Lunel, where he probably died about 1190. His son Samuel, who died at Marseilles about 1230, was equally prolific. He translated the *Mōreh Nebhūkhīm* during the life of the author, and with some help from him, so that this may be regarded as the authorized version; Maimonides's commentary on the Mishnah tractate *Pirgē Abhōth*, and some minor works; treatises of Averroes and other Arabic authors. His original works are mostly biblical commentaries and some additional matter on the *Mōreh*. His son Moses, who died about the end of the 13th century, translated the rest of Maimonides, much of Averroes, the lesser Canon of Avicenna, Euclid's *Elements* (from the Arabic version), Ibn al-Jazzār's *Viaticum*, medical works of Ḥunain ben Isaac (Johannitius) and

Razi (Rhazes), besides works of less-known Arabic authors. His original works are commentaries and perhaps a treatise on immortality. His nephew Jacob ben Makhir, of Montpellier (d. about 1304), translated Arabic scientific works, such as parts of Averroes and Ghazzali, Arabic versions from the Greek, as Euclid's *Data*, Autolycus, Menelaus (מנילאוס) and Theodosius on the Sphere, and Ptolemy's *Almagest*. He also compiled astronomical tables and a treatise on the quadrant. The great importance of these translations is that many of them were afterwards rendered into Latin, thus making Arabic and, through it, Greek learning accessible to mediaeval Europe.

Another important family about this time is that of Qimhi (or Qamhi). It also originated in Spain, where Joseph ben Isaac Qimhi was born, who migrated to Southern France, probably for the same reason which caused the flight of Maimonides, and died there about 1170. He wrote works on grammar, commentaries on Proverbs and the Song of Solomon, an apologetic work, *Sepher ha-berith*, and a translation of Bahya's *Höbhöth ha-lebhabhōth*. His son Moses (d. about 1190) also wrote on grammar and some commentaries, wrongly attributed to Ibn Ezra. A younger son, David (Radaq) of Narbonne (d. 1235) is the most famous of the name. His great work, the *Mikhlol*, consists of a grammar and lexicon; his commentaries on various parts of the Bible are admirably luminous, and, in spite of his anti-Christian remarks, have been widely used by Christian theologians and largely influenced the English authorized version of the Bible. A friend of Joseph Qimhi, Jacob ben Me'ir, known as Rabbenū Tam of Ramerupt (d. 1171), the grandson of Rashi, wrote the *Sepher ha-yashar* (novelae and responsa) and was one of the chief Tosaphists. Of the same school were Menahem ben Simeon of Posquières, a commentator, who died about the end of the 12th century, and Moses ben Jacob of Coucy (13th century), author of the *Semag* (book of precepts, positive and negative) a very popular and valuable halakhic work.

A younger contemporary of David Qimhi was Abraham ben Isaac Bedersi (i.e., of Béziers), the poet, and some time in the 13th century lived Joseph Ezobhi of Perpignan, whose ethical poem, *Qe'arath Yōsephi*, was translated by Reuchlin and later by others. Berachiah, the compiler of the "Fox Fables" (which have much in common with the "Ysopet" of Marie de France), is generally thought to have lived in Provence in the 13th century, but according to others in England in the 12th century. In Germany, Eleazar ben Judah of Worms (d. 1238), besides being a Talmudist, was an earnest promoter of kabbalistic studies. Isaac ben Moses (d. about 1270), who had studied in France, wrote the famous *Or Zarūa'* (from which he is often called), an halakhic work somewhat resembling Maimonides's *Mishneh Tōrah*, but more diffuse. In the course of his wanderings he settled for a time at Würzburg, where he had as a pupil Me'ir of Rothenburg (d. 1293). The latter was a prolific writer of great influence, chiefly known for his Responsa, but also for his halakhic treatises and Talmudic studies. He also composed a number of piyyūtim. Me'ir's pupil, Mordecai ben Hillel of Nürnberg (d. 1298), had an even greater influence through his halakhic work, usually known as the *Mordekhai*. This is a codification of halakhōth, based on all the authorities then known, some of them now lost. Owing to the fact that the material collected by Mordecai was left to his pupils to arrange, the work was current in two recensions, an Eastern (in Austria) and a Western (in Germany, France, etc.). In the East, Tanhūm ben Joseph of Jerusalem was the author of commentaries (not to be confounded with the *Midrash Tanhūmā*) on many books of the Bible, and of an extensive lexicon (*Kitāb al-Murshid*) to the Mishnah, all in Arabic.

Limit of Development.—With the 13th century Hebrew literature may be said to have reached the limit of its development. Later writers to a large extent used over again the materials of their predecessors, while secular works tend to be influenced by the surrounding civilization, or even are composed in the vernacular languages. From the 14th century onward only the most notable names can be mentioned. In Italy Immanuel ben Solomon, of Rome (d. about 1330), perhaps the friend and certainly the imitator of Dante, wrote his diwan, of which the last

part, "Topheth ve-'Eden," is suggested by the *Divina Commedia*. In Spain Israel Israeli, of Toledo (d. 1326), was a translator and the author of an Arabic work on ritual and a commentary on *Pirgē Abhōth*. About the same time Isaac Israeli wrote his *Yesōdh 'Olam* and other astronomical works which were much studied.

Jacob ben Asher of Toledo (d. 1340), was the author of the *Tūr* (or the four *Tūrīm*), an important code of Jewish law. His pupil, David Abudrahim, of Seville (d. after 1340), wrote a commentary on the liturgy.

Both the 14th and 15th centuries in Spain were largely taken up with controversy, as by Isaac ibn Pulgar (about 1350), and Shem Tōbh ibn Shaprūt (about 1380), who translated St. Matthew's gospel into Hebrew. In France Jedaiah Bedersi, i.e., of Béziers (d. about 1340), wrote poems (*Behinath ha-'ōlam*), commentaries on agada and a defence of Maimonides against Solomon Adreth. Levi ben Gershom (d. 1344), called Raibag, the great commentator on the Bible and Talmud, in philosophy a follower of Aristotle and Averroes, wrote also many works on halakhah, mathematics and astronomy. Joseph Kaspi, i.e., of Largentière (d. 1340), wrote a large number of treatises on grammar and philosophy (mystical), besides commentaries and piyyūtim. In the first half of the 14th century lived the two translators, Qalonymos ben David and Qalonymos ben Qalonymos, the latter of whom translated many works of Galen and Averroes, and various scientific treatises, besides writing original works, e.g., one against Kaspi, and an ethical work entitled *Eben Bōhan*. At the end of the century Isaac ben Moses, called Profiat Duran (Efodi), is chiefly known as an anti-Christian controversialist (letter to Me'ir Alguadez), but also wrote on grammar (*Ma'aseh Efod*) and a commentary on the *Mōreh*. In philosophy he was an Aristotelian.

About the same time in Spain controversy was very active. Hasdai Crescas (d. 1410) wrote against Christianity and in his *Or Adōnai* against the Aristotelianism of the Maimonists. His pupil Joseph Albo in his *Iqqarim* had the same two objects. On the side of the Maimonists was Simeon Duran (d. at Algiers 1444) in his *Magen Abhōth* and in his numerous commentaries. Shem Tōbh ibn Shem Tōbh, the kabbalist, was a strong anti-Maimonist, as was his son Joseph of Castile (d. 1480), a commentator with kabbalistic tendencies but versed in Aristotle, Averroes and Christian doctrine. Joseph's son Shem Tōbh was, on the contrary, a follower of Maimonides and the Aristotelians. In other subjects, Saadyah ibn Danān, of Granada (d. at Oran after 1473), is chiefly important for his grammar and lexicon, in Arabic; Judah ibn Verga, of Seville (d. after 1480), was a mathematician and astronomer; Solomon ibn Verga, somewhat later, wrote *Shebet Yehudah*, of doubtful value historically; Abraham Zakkuth or Zakkuto, of Salamanca (d. after 1510), astronomer, wrote the *Sepher Yuhasim*, an historical work of importance. In Italy, Obadiah Bertinoro (d. about 1500) compiled a very useful commentary on the Mishnah. His account of his travels and his letters are of great interest. Isaac Abravanel (d. 1508) wrote commentaries (not of the first rank) on the Pentateuch and Prophets and on the *Mōreh*, philosophical treatises and apologetics, such as the *Yeshū'oth Meshihō*, all of which had considerable influence. Elijah Delmedigo, of Crete (d. 1497), a strong opponent of Kabbalah, was the author of the philosophical treatise *Behinath ha-dath*, but most of his work (on Averroes) was in Latin.

Later Writers.—The introduction of printing (first dated Hebrew printed book, Rashi, Reggio, 1475) gave occasion for a number of scholarly compositors and proof-readers, some of whom were also authors, such as Jacob ben Hayyim of Tunis (d. about 1530), proof-reader to Bomberg, chiefly known for his masoretic work in connection with the Rabbinic Bible and his introduction to it; Elias Levita, of Venice (d. 1549), also proof-reader to Bomberg, author of the *Massoreth ha-Massoreth* and other works on grammar and lexicography; and Cornelius Adelkind, who however was not an author. In the East, Joseph Karo (Qārō) wrote his *Bēth Yōseph* (Venice, 1550), a commentary on the *Tūr*, and his *Shulhan 'Arūkh* (Venice, 1564) an halakhic work like the *Tūr*,

which is still a standard authority. The influence of non-Jewish methods is seen in the more modern tendency of Azariah dei Rossi, who was opposed by Joseph Karo. In his *Me'or 'Enayim* (Mantua, 1573) Dei Rossi endeavoured to investigate Jewish history in a scientific spirit, with the aid of non-Jewish authorities, and even criticizes Talmudic and traditional statements.

Another historian living also in Italy was Joseph ben Joshua, whose *Dibhrê ha-yamim* (Venice, 1534) is a sort of history of the world, and his *'Emeq ha-bakkah* an account of Jewish troubles to the year 1575. In Germany David Gans wrote on astronomy, and also the historical work *Zemah David* (Prag, 1592). The study of Kabbalah was promoted and the practical Kabbalah founded by Isaac Luria in Palestine (d. 1572). Numerous works, representing the extreme of mysticism, were published by his pupils as the result of his teaching. Foremost among these was Hayyim Vital, author of the *'Ez hayyim*, and his son Samuel, who wrote an introduction to the Kabbalah, called *Shemoneh She'arim*. To the same school belonged Moses Zakkuto, of Mantua (d. 1697), poet and kabbalist. Contemporary with Luria and also living at Safed, was Moses Cordovero (d. 1570), the Kabbalist, whose chief work was the *Parades Rimmônim* (Cracow, 1591).

In the 17th century Leon of Modena (d. 1648) wrote his *Bêth Yehudah*, and probably *Qôl Sakhal*, against traditionalism, besides many controversial works and commentaries. Joseph Delmedigo, of Prag (d. 1655), wrote almost entirely on scientific subjects. Also connected with Prag was Yôm Tôbh Lipmann Heller, a voluminous author, best known for the *Tôsaphôth Yôm Tôbh* on the Mishnah (Prag, 1614; Cracow, 1643). Another important Talmudist, Shabbethai ben Me'ir, of Wilna (d. 1662), commented on the *Shulhan 'Arûkh*. In the East, David Conforte (d. about 1685) wrote the historical work *Qôrê ha-dôrôth* (Venice, 1746), using Jewish and other sources; Jacob ben Hayyim Zemah, kabbalist and student of Luria, wrote *Qôl be-ramah*, a commentary on the *Zohar* and on the liturgy; Abraham Hayekini, kabbalist, chiefly remembered as a supporter of the would-be Messiah, Shabbethai Zebhi, wrote *Hôd Malkûth* (Constantinople, 1655) and sermons.

In the 18th century the study of the kabbalah was cultivated by Moses Hayyim Luzzatto (d. 1747) and by Elijah ben Solomon, called Gaon, of Wilna (d. 1797), who commented on the whole Bible and on many Talmudic and kabbalistic works. In spite of his own leaning towards mysticism he was a strong opponent of the Hasidim, a mystical sect founded by Israel Ba'al Shem Tôbh (Besht) and promoted by Baer of Meseritz. Elijah's son Abraham (d. 1808), the commentator, is valuable for his work on Midrash. An historical work which makes an attempt to be scientific, is the *Seder ha-dôrôth* of Yehiel Heilprin (d. 1746). These, however, belong in spirit to the previous century.

MODERN HEBREW LITERATURE

Modern Hebrew literature is universal in scope and secular in spirit, thus contrasting with the purely legal, ritualistic or homiletic works of earlier times. This literature took its rise in Italy (M. H. Luzzatto, 1707-47), whence it shifted to Germany, showing at first, notably through the influence of Moses Mendelssohn (1729-86), a rationalistic and cosmopolitan tendency.

Russia and Lithuania.—Following a brief period of activity in Galicia dominated by Biblical criticism and historical scholarship (Krochmal, 1785-1840; Rapoport, 1790-1867), Hebrew literature assumed a new character in Russia and Lithuania, where the so-called Haskalah movement developed—a humanistic and humanitarian spirit which set itself against the traditional exclusiveness of the Jew. It found expression in the historical and scientific compendia of Kalman Schulman (1819-99), in the novel (Mapu, 1808-67) and in poetry (Lebensohn, 1828-52; J. L. Gordon [1831-92]). The novelist P. Smolenskin (1842-85) heralded a reaction, hastened by the pogroms against the Jews, towards a Jewish national policy, which culminated in Zionism. Since his day Hebrew literature has been largely dominated by the idea of a national revival. This idea has found its most complete expression in the essays of Asher Ginzberg (Ahad Ha'am) who has resisted the tendency to lay undue stress on the economic and political factors in Zionism and has insisted on the concep-

tion of Palestine as the cultural centre of the Hebrew race.

The individualistic and symbolic spirit in Hebrew literature has been greatly influenced by the modern mystic movement among the Jews known as Hassidism. In the sphere of fiction this spirit found its foremost representative in Isaac Loeb Perez (1851-1915), whose stories are distinguished by artistic beauty and tenderness. Humour is the dominant characteristic of S. J. Abramowitsch, a short-story writer (known as "Mendele," 1835-1918). Judah Steinberg (1863-1908), author of many stories, excels in the delineation of character, and in him the individual finds more complete and varied representation than elsewhere in Hebrew literature. This fact, and the clearness and fluency of his style, give him high rank among Hebrew novelists. Another novelist of some distinction is R. A. Braudes (1851-1902), who chose the struggle for religious reform as the theme of his principal novels.

Poetry.—Poetry has made rapid strides in modern Hebrew literature. There is a host of contemporary poets, the most representative of whom is Hayyim Nachman Bialik (1873-). With the exception of Judah ha-Levi (fl. 12th century) he is perhaps the leading Jewish national poet, inheriting the idealism and the prophetic seriousness of his people. He is pre-eminently the poet of Jewish woe. To Jewish national hopes and aspirations he seldom gives expression in his verse. None of the Hebrew poets has grasped and represented the spirit of the Ghetto and its poetry with so much sympathy and so much tenderness of feeling as Bialik. The ideas of Ahad Ha'am and the influence of Gordon's style and form are traceable in his poems. Next to Bialik and in strong contrast with him stands Dr. Saul Tschernichowski (1875-

). He was the first to introduce into Hebrew poetry an admiration for the Greek spirit and the sense of complete enjoyment of life. His work is remarkable for its easy gracefulness and its varied rhythms and metrical forms. Dr. Jacob Cahan (1880-

), is an idealist, whose poems bear the stamp of a marked individuality. In the poems of Zalman Schneor (1886-) there is at times a gentle pessimistic vein, and his verse is full of life and beauty; the rhythm has harmony and tunefulness, the imagery is rich, varied and striking, and the movement quick and bold. His prose, too, is marked by the same qualities. Among a list of poets of less distinction may be mentioned Jacob Steinberg, Jacob Fichman, Isaac Katzenelson, J. J. Koplewitz, David Schimonwitz, the brothers Simon and Pesach Ginsburg, Hillel Bavli, Judah Karni, A. Schlonsky, Uri Zebi Greenburg, Avigdor Feuerstein, Benjamin N. Silkiner and Simon Leo Halkin. Modern Hebrew poetry, like Hebrew poetry in general, has been strongest in lyric.

Fiction.—The various transformations of Jewish life brought about by the Zionist and other Jewish movements and the influence of foreign literatures had their effects upon the shaping of contemporary Hebrew fiction, notably the short story and the novel. There has been created a Hebrew short story, artistic in technique and generally psychological in presentation, delineating the individual in a variety of moods and situations; but at the same time marked by a minute, torturing self-analysis, by an impotence in the will of the heroes and by an outlook upon life that is gloomy and despondent. The creators of these stories are followers of Micah Joseph Berdyczewski (1865-1921), who in his view of life was influenced by the individualistic theories of Nietzsche. Among the most notable story-writers of this group are Isaiah Domoshevitzy (known as J. Bershadsky, 1870-1908), Joseph Hayyim Brenner (1881-1921), Gershon Schofmann, Uri Nisan Gnessin (1880-1913) and Isaac Dob Berkowitz. The melancholy and morbid spirit which some of these writers have introduced into the Hebrew sketch and novel is almost entirely traceable to the influence of the Russian and Scandinavian literatures of the last few decades. A notable exception to this tendency is S. J. Agnon, an original symbolico-mystical writer of short stories and a master of Hebrew style. Other writers of fiction who are free from this pessimistic strain are A. A. Kabak, Moses Smilansky, L. A. Orloff, S. Ben-Zion Guttman, Eliezer Steinman, Asher Barash, A. Reubeni and Abraham Soyer.

Other Works.—The adaptation of the Hebrew language to

the needs of modern life owes much to Eliezer Ben-Yehuda (1858-1923), one of the pioneers of the idea of a Jewish national renaissance, whose ten-volume Hebrew dictionary (*Thesaurus totius Hebraicitatis*) is a monument of a life's devotion to the revival of Hebrew. The talent of David Frischmann (1863-1922) extended over the domains of the feuilleton, the short story, poetry and criticism. Dr. Joseph Klausner (1874-) is active in many fields—criticism, history, scholarship and journalism. He possesses considerable erudition and historic insight. Hillel Zeitlin, a mystic, has made original contributions to various phases of modern Hebrew literature. The greatest Jewish journalist, writing for Jews in Hebrew and in many other languages, is Nahum Sokolow. Reuben Brainin is a fine stylist and an able critic but his literary ideas and tastes are perhaps too much determined by outside influences. In Dr. Simon Bernfeld (1860-

) Hebrew literature has a many-sided and very prolific writer with a gift for presenting the results of scholarly research in attractive literary form. Wolf Jawitz (1847-1924) was a historian and a philosopher of religious romanticism. David Neumark (1866-1924) made original contributions to the study of Jewish philosophy. Jacob Klatzkin, Fishel Lachower, S. B. Maximon, Dr. S. M. Melamed, Joel Blau, Osias Thon, Mordecai Ehrenpreis, S. I. Hurwitz, Dr. M. Waxman and others have contributed much to the development of the essay in Hebrew literature.

Hebrew literature, including its vernacular, is a primary factor responsible for the rejuvenation of the national Jewish spirit and for the emancipation of Jewish life from external influences. Literary activity came to a virtual standstill as a result of the World War and its consequences, which bore with especial severity on eastern Europe, formerly the chief centre of Hebrew literature. During the last few years there has been a revival in eastern Europe, and a certain development in America; but the centre of this activity has shifted to Palestine.

BIBLIOGRAPHY.—Only the more comprehensive works are mentioned here, omitting those relating to particular authors, and those already cited. Introductory: Abrahams, *Short History of Jewish Literature* (London, 1906); Steinschneider, *Jewish Literature* (London, 1857); Winter and Wünsche, *Die jüdische Literatur* (Leipzig, 1893-95) (containing selections translated into German).

For further study: Graetz, *Geschichte der Juden* (Leipzig, 1853, etc.) (the volumes are in various editions), with special reference to the notes; English translation by B. Löwy (London, 1891-92) (without the notes); Zunz, *Gottesdienstliche Vorträge der Juden* (new ed., Frankfurt-on-Main, 1892); Zur *Geschichte und Literatur* (Berlin, 1845). Steinschneider, *Arabische Literatur der Juden* (Frankfurt-on-Main, 1902); *Hebräische Übersetzungen des Mittelalters* (Berlin, 1893).

On particular authors and subjects there are many excellent monographs in the *Jewish Encyclopaedia* (New York, 1901-06), to which the present article is much indebted.

N. Slouschz, *La renaissance de la littérature hébraïque* (1903), with English translation by Henrietta Szold (1909); id., *La poésie lyrique hébraïque contemporaine, 1882-1910* (1911); Jacob S. Raisin, *The Haskalah Movement in Russia* (1913); Israel Cohen, *Jewish Life in Modern Times* (1914); S. Dubnov, *History of the Jews in Russia and Poland*, 3 vol. (1916-20); Joseph Klausner, *Geschichte der Neuhebraischen Literatur* (1921); J. L. Landau, *Short Lectures on Modern Hebrew Literature* (1923); Joseph Reider, "Negative Tendencies in Modern Hebrew Literature" in *Hebrew Union College Jubilee Volume*, pp. 445-482 (1925); A. S. Waldstein, *Evolution of Modern Hebrew Literature, 1850-1912* (1916). (J. BL.)

HEBREW RELIGION. The Hebrews were Western Semites, and from the Semites sprang Judaism, Christianity and Mohammedanism (or Islam). The part these three great monotheistic religions have played in history cannot be understood without taking into account the general characteristics of the SEMITES (*q.v.*), and the capacity for monotheism often ascribed to them. But monotheising tendencies are not so rare, and it is more important to observe what effects they have had.

1. **Introductory.**—By Judaism is meant the religion of the Jews (*i.e.*, properly "Judaicans") based upon the Old Testament. There are, however, striking differences within the Old Testament, *e.g.*, between the piety of the Psalms, the pessimism of Ecclesiastes and the eroticism of Canticles; or between the popular stories in Genesis and the priestly ritual in Leviticus. Moreover, it is instructive to compare and contrast the treatment of the history of the monarchy in Samuel—Kings with the parallel portions in Chronicles. Further, the prophets condemn the poly-

theistic and degrading cults of the Israelite religion of their day, although the Israelites felt that they stood apart from their neighbours, whether Canaanites within the land, or other peoples without: Edom, Ammon, etc. In fact, "Israel" is a much more restricted term than "Hebrew" (*see* JEWS, § 3). Israel, which strictly includes both Judah and the northern tribes (Joseph, Ephraim, etc.), was closely related to Edom (its "brother"), Moab and Ammon, the Aramaeans of north Syria and the Arabs of the desert. Hence, while the Old Testament (with the religion of Israel) led to both Judaism and Christianity, one must not ignore the religious beliefs and practices over the larger world of which Israel formed part. The ideas which made the monotheistic religion of Israel unique are best appreciated when it is seen how they developed, now in touch with and now in reaction against, the contemporary religions. By Hebrew religion, therefore, we mean the religion of the Hebraic background upon which Israel grew up and developed its monotheism, and which extends outside the chronological limits of the Old Testament. (*See* BIBLE: Old Testament.)

2. **Desert and Other Influences.**—Intercourse over south-west Asia, Egypt and the Levant, regular from a very early date, was at times pronounced. Under varying political and economic circumstances the tide of influence flowed now in one direction, now in another. In the age after Alexander the Great (332 B.C., *see* HELLENISM), the Greeks left their mark upon the East; but, later, Christianity belongs to a new Oriental revival and its conquests westwards, together with the activity of Rabbinical Judaism, and the vitality of old Oriental pagan or semi-pagan cults and ideas, characterise the ages before the rise of Islam among the Arabs (seventh cent. A.D.). From time to time sweeping movements can be distinctly traced, others only inferred; and there is reason to believe that the history of religion in Palestine and Syria—Hebrew religion—was more complicated and more closely bound up with far-reaching external events than would be supposed from the biblical narrative alone. Yet even there the writers are convinced that the history of the religion of Israel was one of universal significance.

The rise of militant Islam, virile and enthusiastic, with the doctrine of a one and only god Allah, is not entirely unique in so far as the influence of desert tribes upon Semitic history and religion can be traced earlier. The Israelites themselves admit their indebtedness to the formative period in the deserts outside Palestine and to Kenites or Midianites. The story of the flight from Egypt, the Exodus, and the sweeping invasion of tribes under Joshua, the successor of their law-giver Moses, reflects the belief that the national religion of Israel, with the worship of a one and only god Yahweh (on the name *see* JEHOVAH), was introduced into a land of ancient, though depraved civilization by men who had lived under the simpler conditions of the deserts. On the other hand, the story of the "patriarchs" in Genesis and especially the connections with Ur of the Chaldees and Harran (*see* ABRAHAM), point back to famous ancient centres of culture. Difficult as it is to decide whether the desert (nomadic or semi-nomadic) origin is more significant than the traditions (Gen. xi. sqq.) pointing to Babylonia, North Syria and even Armenia (Ararat), there are yet other factors to take into account: excavation and the monuments lead us to look for influences from Egypt, Asia Minor, Cyprus, Crete and the Aegean. Accordingly, the study of Israel's own literature (*viz.*, the Old Testament), together with that of the "external evidence," brings many difficult problems, and scholars take different attitudes in regard to the evidence, and sometimes reach very divergent conclusions. On the line taken in the present article, *see* further JEWS, PALESTINE: History.

3. **The Amarna Age.**—The age to which the biblical writers evidently ascribe Abraham and the beginning of Hebrew religion is approximately that of the Middle Egyptian empire and of the First Babylonian Dynasty, the chief of whose monarchs, Hammurabi, extended his power to the west. Its significance for the development of religion in Palestine can hardly as yet be safely calculated. On the other hand, a firm foundation is afforded by the Amarna age (*c.* 1400 B.C.), an international age when the

widespread use of the Akkadian language and script points to the earlier influence of Mesopotamia. But the native language of Palestine (including Phoenicia) was already virtually that of the Hebrew Old Testament; and the phraseology of the letters, although Akkadian, is of great interest. The letters are addressed by the petty kings of the land to their Suzerain, the Egyptian Pharaoh (Amenhotep III. and IV.) who, in accordance with ancient usage, is regarded as a more or less divine representative of the supreme god or gods. A "loyal" king is *suduk* (the Heb. *saddiq*, "righteous"), he lays his neck to the yoke, and is more unshakable than a brick. A city forsaken by Egypt "weeps, its tears run down, there is no taking hold of the hand" (i.e., no help). The "name" of the loyal vassal endures for ever, while that of the bad one perishes. The king "sets his face" against the disloyal (disloyalty is "sin") but his breath (or spirit) gives life and rest. He is the breath of men (cf. Lam. iv. 20), and without it they cannot live. "If" says one, "we go up into heaven, or if we descend into the earth, yet is our head in thy hands" (cf. Ps. cxxxix. 7 seq.). The Pharaoh's name spreads fear, and because he has set his name upon Jerusalem for ever, its king Abdi-khiba is confident that it must not be neglected. He even declares that the Pharaoh has "set his name at the rising of the sun and at the setting of the sun" (cf. Mal. i. 11): a recognition of the world-wide power of the human representative of the great Egyptian gods, of one whom his vassals call their god or their gods (a plural used like the Heb. *Elohim*). Language of this sort clearly shows how the people of Palestine could address their own gods (or their human representatives).

Centuries of intercourse had created a common background of life and thought; and the deities of one land were often known to another. In Palestine can be found Dagan or Dagon (probably a food god), Nebo (the messenger god), Sin (moon-deity), Nergal and Ninurta. Certain Asiatic deities were known in Egypt: Resheph, Baal and the warrior mother-goddesses Anath, Kadesh and Astarte (Ishtar). Various Egyptian deities entered Palestine (Amon, Re, Hathor, etc.); and Egyptian colonies, temples and symbols (the *Ankh* or "sign of life," the winged-disc) combine with archaeological evidence for contact with Asia Minor and the Aegean, to prove that then, as always, the land was the meeting-place of beliefs. Doubtless there were then, as later, local deities (*Baal*, fem. *Baalath*), closely identified with local districts or possessing specialised functions, differing in name or attribute, but the centre of very similar beliefs and practices (see *BAAL*). Especially significant is the recognition of the supreme monarch, since it involved a tendency towards monotheism (a one and only god), or rather henotheism (one god above all others). The Amarna letters show how, under Egyptian supremacy, Egyptian and Palestinian deities were co-ordinated or equated. The vassal princes call the king their Shamash and Addu; the former, the Sun-god, god of right and justice, was already familiar (cf. also the place Beth-shemesh near Jerusalem), and Addu (Hadad) god of rain, storm, etc., was known widely under other names (Ramman [Rimmon], Teshub, etc.). He was presumably "the Baal," the prominent god associated with thunder and lightning and, with the bull, often named in Egypt in the XIXth Dynasty. The name Shamshi-Adad, borne by five Assyrian kings (1850-1000 B.C.), definitely united the two pre-eminent deities, and in a cuneiform tablet found at Taanach (in the Plain of Jezreel) a "lord of the gods" is invoked. Both in Egypt and in Babylonia (*viz.*, the Code of Hammurabi) there is the conception of "a (or the) god"—not closely defined, but quite clearly understood—other than the named and recognised deities; and consequently important monotheising tendencies are to be recognised before the rise of the national religion of Israel.

4. The Religious Significance of the Amarna Age.—The strenuous reforms associated with the name of Amenhotep IV., Ikhnaton (c. 1380 B.C.), made the Sun the source of all power and life; and of his Sun-god (Aton) he was the "beloved son" and emanation, born of his rays, eternal. Ideas of the intimate bond uniting national god and king were not necessarily strange to Palestine; and may have been further developed by the marriage relations between the Amenhoteps and the non-Semitic

dynasty in Mitanni (North Mesopotamia). Abdi-khiba of Jerusalem, most devoted of vassals of Egypt, was himself one of several dynasts who can be traced from Mitanni southwards. There, in the north, among various signs of Indo-European (Aryan or Iranian) influence, a treaty between Mitanni and the Hatti (Hittites) actually names Varuna, Mitra (later Mithra) and other Indian or Aryan deities. Indo-European thought in general is distinguished by the recognition of a reign of law, a rational or natural rather than a supernatural order (Sanskrit *rita*, Iranian *arta*), and to judge from various dynastic and other names, it was already known in Mitannian circles. A certain rationalism and pragmatism mark off Iranian (Persian) religion from Indian mysticism, pantheism and quietism; and accordingly it is probable that there was an Aryan or Iranian influence in Palestinian or Hebrew religion centuries before the age of the Persian (Achaemenid) empire, when Zoroastrianism was an important factor in the history of Judaism (cf. 16).

In the Amarna age, which is approximately that of Moses, religion had reached an advanced stage, and ethical ideas frequently recur in ancient Babylonia and Egypt, and were especially associated with solar deities. But apart from the O.T. no clear trace is to be found of Yahweh, at least as a prominent god, still less of the covenant with Israel at Sinai (Horeb), yet the Aryan Varuna and Mitra were gods of oath and covenant; and the lofty ethical character of the former points to some earlier ethico-spiritual reform outside the Semitic world, to which the rise of Zoroaster's Ahura-Mazda (who corresponds to Varuna) is a later parallel. The Amarna letters refer to a very powerful anti-Egyptian movement. The land was rent by intrigues; and, as always, religion and politics were one. The pro-Egyptian petty princes, both native and (like Abdi-khiba) foreign, would necessarily favour the syncretistic religion that Egyptian supremacy involved, whereas the enemies of Egypt, the Khabiru, the Amorites under Abd-Ashirta, whose name styles him a "servant of Ashirat" (Astarte or Ishtar), their Palestinian allies and their Hittite supporters, would promote the native religion. As often later, Palestine in politics and religion wavered between Egypt and the north (Mesopotamia, etc.). The religion was affected by and reacted against contemporary conditions, and the Amarna age marks the beginning of the decline of Egypt, and the increase of Hittite and Amorite influences. It is perhaps significant that "Baal" now becomes familiar in Egypt in the XIXth and XXth dynasties. External evidence throws no light upon the rise of Yahwism, as described in the O.T., but a new stage in the history of religion in Palestine can undoubtedly be recognised.

5. The Hebrew Monarchy.—During the next few centuries sweeping movements changed the face of the land. Hittite and Amorite elements gravitated southwards, and Ezekiel (xvi. 3) calls Jerusalem the offspring of an Amorite and a Hittite. New states came into being, and the Hebrew monarchy arose (c. 1025 B.C.) in a national movement which overcame the recently settled Philistine and other Levantine invaders (see *Jews*, § 5, seq.; *PALESTINE*, § 4, seq.; *PHILISTINES*). Yahweh has now become "the god of the Hebrews" (cf. the designation, Ex. iii. 18, etc.), and the people of Israel are his people. Archaeology and the monuments indicate continued intercommunication over a wide area; and the changes since the Amarna Age are not so extensive as might be expected. But from Sam'al (Zenjirli) in extreme north Syria to Jerusalem and Moab we find an alphabetic script (see *ALPHABET*) with almost identical forms, and an almost identical language (Hebrew, Phoenician, Moabite) with a very similar type of thought. This "North Semitic" alphabet is beginning (c. 700 B.C.) to develop along separate paths (Hebrew, etc., and Aramaean), and the Aramaic language in use in North Syria is extending, and is destined to be the *Lingua franca* of the Persian empire. Hence there would seem to have been some great *bloc*—Amorite? Hebrew?—of interrelated states from Sam'al (the name itself means "north") downwards, and to this the traditions of the far-reaching sway of David and Solomon (*qq.v.*) might conceivably refer.

In Sam'al the dynasts have non-Semitic names, but the gods include Hadad, El ("god" *par excellence*) and Resheph. In

Hamath are sun and moon deities, and gods of heaven and earth. The Baal of Heaven or Sky-god, found at Hamath and Tyre, and known earlier to Hittites and Amorites, was presumably Addu (Hadad) who, with his Aramaean equal, Rammān, is found in Hadad-rimmon, near where excavation at Beth-shan has illustrated the persistence of Egyptian, Aegean and northern influences. Yahweh of Israel, Chemosh of Moab and Milkom of Ammon are three parallel gods of three closely interrelated peoples, but the name Hadad appears in the dynasties further removed—in Damascus and Edom. It is only to be expected that the Israelite Yahweh took over some of the attributes of the earlier gods, and the name Addu appears in the 10th century in Adoram, the name of a prince of Hamath otherwise called Joram, and of one of Solomon's officers (also spelt Hadoram) otherwise called Adoniram, where Addu interchanges respectively with Yo (Yau, Yahweh) and Adon (as in Adonijah, etc.). Moreover, Yau (Yahweh) may probably be traced in the 8th century names Yaubi'di of Hamath and Azriyau of Yaudi. National and religious movements were one, and when Pharaohs spread the name and cult of their god, and Sargon II. sent skilled men to teach "the fear of god and the king" (Cyl. Inscr. 72-74), successful kings of Palestine would not be behind.

Under the famous Omri dynasty (c. 887-841 B.C.) Ahab of (north) Israel was related by marriage to the Sidonian priest-king of Astarte; and was an important constituent of an alliance led by Hamath and Damascus against Assyria. Although Ahab recognised Yahweh, and his family bear the distinctive names Ahaziah, Jehoram and Athaliah, the age is one of (1) Elijah's firm stand for Yahweh against Baal, (2) separation from the northern alliance and (3) dynastic changes in the course of a revolt in which desert influence can be traced. The middle of the 9th century B.C. is, in fact, another great landmark in the history of Hebrew religion, though it is difficult to determine precisely the changes. (See ELIJAH, JEWS.)

6. The Rise of the Prophets.—The dynasty of Jehu perished, after a stormy century (c. 841-745 B.C.). About 25 years later the northern kingdom fell, and the kingdom of Judah came face to face with Assyria (see JEWS, § 8, *seq.*, PALESTINE, § 7, *seq.*). With this, the Assyrian age, a line of prophets arose, and transformed the old Hebrew religion, giving it its specific Israelite form (see PROPHET). To be more accurate, on the ordinary view of the O.T. they merely restated the religion introduced by Moses now many centuries previously, whereas modern critical opinion would hold that they "for the first time unfolded the true character of Yahweh, implicit in the old Mosaic religion." Opinion, however, would differ on how far the old religion could be recovered, or could be inferred from an analysis of the religion after the prophets; and the view here taken is that the prophets are a surer guide than the compiled accounts of the pre-prophetic period.

What the prophets condemn is not the absence of religion, but its quality—the ineffectiveness of the sacrificial and other offerings, the festivals and the priests. Amos proclaims that Yahweh was a universal god of unchangeable righteousness, unfettered by any natural bond between himself and his own people. He attacks the old type of group religion where the god was an integral part of the local or national body, furthering the interests of worshippers who possessed the machinery for gaining his favour or placating his wrath. Such group religion was intensive and cohesive; but although it involved a certain degree of morality within the group, it fostered unethical conceptions of the relation between gods and men.

In the days of Amos and Hosea (qq.v.) Israel had entered into world-history. Almost overwhelmed by its former ally Damascus, it had been brilliantly restored by Jeroboam II. These were no mere inter-state rivalries; the great powers of Assyria and of Urartu (Ararat, Armenia) themselves had been behind these vicissitudes. Yahweh's relation to Israel was that of Chemosh to Moab (Judg. xi. 24), and Chemosh had aroused Mesha (as he records on the Moabite Stone) (c. 850 B.C.) to recover lost territory. But Israel had now seen Yahweh moving history on behalf of his own people. It remained a characteristic conviction,

and some prophets are more nationalistic than others. Amos, however, shifted the emphasis from Israel's god who had restored his people to a universal God whose relation to all peoples alike was based on an eternal moral law, and who required a higher standard of life from an Israel who claimed to stand in a unique relationship to him (Am. iii. 2). The prophets taught that Yahweh was behind history; Egypt, Assyria and Babylonia were tools in his hand—but no more than tools, and must not boast, for Yahweh who threatens Israel, or punishes her by defeat or exile, continued to be the god who sought his own people (cf. later Paul in Rom. xi.). The prophets extended the group-conception; Yahweh was the god not merely of the visible or acknowledged body of Israel, but of the poor and needy, and of all who served him and sought his help. The old group-unit of *group + god* was to depend, not upon the nature of the group, but upon what Yahweh demanded of the group that claimed to be his.

7. The Old Religion.—The prophets treat the cult as secondary, as an accretion (Am. v. 25, Jer. vii. 22). It is saturated with crude ideas and immoral practices that disintegrate society (cf. HIGH PLACE). Hebrew religion was anthropomorphic and passionate. Men fed the god, ate with him and saw his face (Hezekiah lays a letter before him, Is. xxxvii. 14). It was necessarily practical, for men depended upon trade (note the naive ideas in Deut. xxviii. 12, 44), and upon the fertility of man, beast and the field. No goddess is openly associated with Yahweh, though female deities abounded, and the numerous plaques of the mother-goddess, models of heads of bulls, and phallic objects unearthed by excavation, illustrate elemental ideas of growth and increase, and illustrate the prophet's condemnation of impure rites. Although the old religion included elevated ideas, it involved beliefs in the interconnection of men and nature, and it did not exclude the licentious practices (condemned, e.g., by Hosea) which were evidently more than mere immorality. It was a persistent conviction that nature shared man's distress and that man's behaviour might react upon nature. The sensuous and sensual elements in religion proved almost ineradicable; and the fact remains that Hosea (second half of 8th cent. B.C.) in attacking the impure cults, clearly a recognized part of the ordinary religion, has to teach, as though for the first time, that Yahweh, and not the local, or functional, Baals, gave nature's blessings and provided for man's most vital needs.

8. Jerusalem and the Monarchy.—The sanctuaries (Bethel, Gilgal, Shechem, etc.) have a bad reputation; Jerusalem was no better. Its religious history is pre-Israelite, and near by, at Ed-Dra' in Moab, traces have been found of an ancient sacred locality, perhaps a place of pilgrimage, dating back to the Hyksos age. With Anathoth (the Anaths), Nob (Nebo), Tophet and the valley of Hinnom (Gehenna), Jerusalem with its sacred Mount Zion was a religious centre of unknown origin. The temple, the abode of the god and part of the royal buildings, with the pillars Jachin and Boaz, the horses of the sun and the sacred chariot, the cherubim and other belongings, the orgiastic festivals and extravagant sacrifices, was far from being the home of the spiritual religion which the reforming prophets called for, and the reforms of Josiah (q.v.) and the allusions of Jeremiah and Ezekiel, show to what slight extent the religious conditions were improved.

Jerusalem was the centre of the monarchical idea. Abdi-Khiba received his legitimation—and perhaps, like another vassal, the anointing oil—from his suzerain in Egypt. Later, the David dynasty has taken root. The royal throne was the throne of Yahweh upon which sat his "anointed" (*māshī'ah*) the representative and embodiment of Yahweh's people (cf. 1 Chron. xxix. 23, 2 Chron. ix. 8, etc.). The king, the "lamp" of the people (2 Sam. xxi. 17, cf. the "coal" in 2 Sam. xiv. 7), takes a prominent part in the national religion; divinely guided, he carries out the Divine Law (cf. Prov. xvi. 10-15); and is responsible for the national welfare. A recollection of priestly kings is preserved in the tradition of Melchizedek (q.v.), and of human sacrifice to the king-god in the worship of Moloch (q.v.). Traces of a divine kingship may be recognised in the Messiah (q.v.), especially as a superhuman being who shall bring peace and plenty. Sovereignty

rests in the people of Israel, so (later) in Deuteronomy; or, as in post-exilic times, the high priest has all the powers and responsibilities of the king of old. The tendency to subordinate the king more deliberately to Yahweh (who appoints him through a prophet) or to the priest (so in Ezekiel's programme) reflects later developments. Characteristic of "biblical" religion is the endeavour to safeguard the supremacy of Yahweh who would have no other gods before him, no intermediary (like the god Marduk in Assyria), no ruler who would set himself upon an equality with the Most High (Is. xiv. 13 *seq.*). Kingship and Yahwism are, none the less, intertwined. The prophet Isaiah, who emphasizes the sterner aspects of Yahweh, develops the idea of Divine Sovereignty; but against the usual arbitrariness of ancient Oriental monarchy is directed the doctrine that "Yahweh is not a man to be capricious" (Num. xxiii. 19). And while, on the one hand, Yahweh's absolute freedom of choice is secured: "I shall be—just what I shall be" (Ex. iii. 14), prophetic teaching centres upon Yahweh's absolute righteousness, and his apparent arbitrariness is due, not to his mood, but to his "righteousness"; Israel's conduct inevitably bringing consequences which, whether beneficial or disastrous are "right." As is only to be expected, the very arbitrariness of the Hebrew autocrat, the representative and vicegerent of his god, brought the problem of Yahweh's character and his treatment of his people.

There are solar, lunar and nature traits in Yahwism, explicable in view of the earlier religion in Palestine, and the way in which it had to satisfy elemental needs. The calf-cults (*see* AARON; CALF, THE GOLDEN; JEROBOAM) associate themselves with the old Hadad, and Yahweh as a war-god (*e.g.*, Ex. xv. 3) goes back to the earlier warrior-god Baal. The human sacrifices and licentious cults which the prophets denounce, the fierceness of Levitical reformers and the barbarities of warfare reflect an intensely emotional religion, characteristic of ancient Oriental peoples, and account for the god fiercely "jealous" of a rival and "zealous" for his people (Ex. xx. 5, Zech. i. 14). Passionate as preachers of a new faith like the prophets, or as priests upholding the holiness of Yahweh, or as kings spreading the kingdom of their god, the Hebrews are distinguished by an intense self-consciousness and confidence which, striking enough in the later stages of the religion, would not be less so before the ethical teaching of the prophets had begun to take effect.

9. Uniqueness of the Prophets.—Amos is the first of the "written prophets" and although he and his successors are pre-eminent for their powerful theistic idealism, they are not wholly isolated. "The Hebrew, whether prophet, psalmist or sage, was a thorough-going partisan, identifying himself with his circle, and identifying his interests with the eternal order" (C. C. Toy, *Comment. on Proverbs*, p. 27). Israel felt herself to be an essential part of the course of history, and the prophets felt that their deepest personal experiences (*cf.* notably Hosea's tragic marriage) had a universal meaning. But whereas the group and god were united in the social group-unit, the individual prophet found in his consciousness of God eternal principles that must work themselves out in the history of individuals and nations. Conscious of an eternal order he, like the group (tribe or nation), felt himself one with past history and future destiny, and he embodied within himself the people for whom he spake as surely as did the representative of the dynasty (or, later of the priesthood), or the individual member of a corporate Israel.

The great prophets mark, however, an immense advance in ideas of God, Man and the Universe. They attacked an old "undifferentiated" type of thought where there was no clearly-drawn distinction between man and "nature" (a relatively modern term), between what is ceremonial or ritual and what is ethical. The step they took corresponds to that from the old Aryan Varuna, the guardian of cosmic (social and natural) order, to the specifically Zoroastrian ethical order, which is under the care of the ethical god Ahura-mazda. The date of Zoroaster (*q.v.*) is disputed, but the rise of Amos and his successors may be associated with the prominence, not only of Assyria and its god Asshur, but also of Urartu (Armenia), and with the imminent rise of the Medes, the forerunner of the Persians. Hebrew religion

thus reached another definite stage, and the dawn of authentic prophecy is part of widespread movements as truly as are the Amarna Age of the now distant past, and the better known complex of events in the Persian age (*cf.* § 14).

10. Jeremiah and Ezekiel.—If Christianity has always found it easy and natural to pass from the prophets of Israel to its own rise, it is because pregnant ideas do not advance continuously, and many centuries had to pass before there again dawned an age as creative as that of the 8th and 7th century B.C. The first four prophets (Amos, Hosea, Isaiah and Micah) belong to the decline and fall of the northern kingdom and the extension of Assyrian power as far as Judah and the gates of Egypt (*see* JEWS, § 11). A century later Judah entered upon its decline and the prophets Jeremiah and Ezekiel form another landmark. How far the books named after them represent schools or tendencies is uncertain; at all events their enunciation of individual responsibility belongs to a day when religious and social organization was rapidly breaking up, and with it the old corporate responsibility of communal life. Jerusalem and the Temple were shortly to be destroyed by the Babylonians (586 B.C.) and religion stripped of its national limitations. Jeremiah is characterized by his indifference to city, temple and cult; Jews in exile could be both loyal to their new home and worshippers of Yahweh (ch. xxix.). Jeremiah hardly anticipated a restoration of the old regime, and Ezekiel is distinctly catastrophic in his expectations of ruin before restoration. But while Jeremiah looks for the New Covenant which Yahweh would write upon men's hearts, Ezekiel demands a purer priesthood (*viz.*, Zadokites of Jerusalem), and these shall safeguard the "holiness" of Yahweh which priests and people had defiled. Yet with all their threats and denunciations the prophets are *Israelite*, in the widest sense: Yahweh, whose mouthpiece they were, could not for ever forsake the people whom they represented.

In obscure circumstances the 6th century B.C., which began with the decline and fall of Jerusalem (586 B.C.) and the exile, closed with the rebuilding of the temple (516 B.C.) and high hopes of a new era under the Davidic Zerubbabel. After another obscure interval Zerubbabel has disappeared and a priestly regime is in control. In the work of Nehemiah (who was probably of royal ancestry) and the priest and scribe, Ezra, the step is taken which may be said to inaugurate post-exilic Judaism (Neh. viii. *sqq.*; 445 B.C.). The old land had been broken up, the disorganization seemed complete, but disintegration gives place to reintegration, a new national consciousness and a new corporate responsibility. The study of the changes from the old monarchies of Israel and Judah to the establishment of what is virtually the Church of Israel at Jerusalem continues to absorb scholars, so vital are the problems. It is, however, generally agreed that the Pentateuch in its present form is post-exilic; it is not, as on the traditional view, a Mosaic work of pre-monarchical origin which has been re-introduced. In any event, it is very remarkable that, notwithstanding the immense political and social changes arising out of the Assyrian conquests, and after the fall of Assyria (612 B.C.), a certain continuity can be traced; and the individualism of an age of disintegration is followed by a rebirth or reorganization of Yahwism, amid the decay or death of the surrounding powers. (*See* JEWS, § 13 *sqq.*; PALESTINE, § 10.)

11. Desert Influences.—The Israelites who invaded Palestine under Joshua, now many centuries ago, intermarried with the native population and learnt their ways (*cf.* Judg. iii. 5 *sq.*). In fact the religion which the prophets denounce is Palestinian rather than of desert origin; and it was so inveterate that it is difficult to determine how much of the Pentateuchal legislation was brought in by the immigrants. The sacrificial ritual, for example, can be compared with both Phoenician and Babylonian usage. But movements of semi-Edomitic and other clans from the desert were far from exceptional, and they can be traced or suspected (a) in Elijah's day, (b) after the fall of Samaria, and (c) after the fall of Jerusalem. But whereas desert clans would succumb to the old civilization of Palestine ("Jeshurun waxed fat and kicked" Deut. xxxii. 15), biblical history concentrates upon the Mosaic age, the Covenant at Sinai (Horeb) and the

Invasion, although the several traditions in question belong—though to what extent is disputed—to late monarchical, exilic and post-exilic periods. Moreover, there are even some traces of hostility towards the desert clans. None the less, Israel feels that its inspiration came from outside a land of effete culture, and the entrance of the “children of Israel” (Exodus-Joshua) into the land wherein the “patriarchs” had once actually settled down (Genesis) looks like a fusion of two absolutely distinct groups of tradition. Moreover analysis of the composite narratives reveals various traditions of South Palestinian origin and interest, likely to belong to clans who ultimately became part of a united Israel. They naturally belong to a time when such clans were able to leave their imprint upon the growth of the Old Testament, and, to the present writer, they appear to belong to the age, after the great prophets. That is to say, the desert influences which admit of being traced appear to belong to relatively late rather than to early movements.

12. **The Sixth Century B.C.**—The popular narratives (Genesis-Samuel), which describe early conditions in Palestine are commonly dated by scholars to an age before the prophets, and are commonly used as material for modern descriptions of pre-Mosaic, pre-monarchic and pre-prophetic religion. On the other hand, they do not seem to reflect the religious conditions which the prophets denounced; they represent popular religious traditions, not *before*, but *after* the reforms. The local sanctuaries are regarded leniently, and the religion, as practical as ever, with its agricultural festivals (*see* however PASSOVER), appears to have been purged of all nature worship. The religious life of the Israelite is bound up with a canonical history of a Chosen People, sons of Abraham, fugitives from Egypt. In striking contrast to royal inscriptions and the didactic and other compositions of the ancient east, there is a view of history which is of unique interest for its democratic spirit. The history of Israel is that of every Israelite and his responsibility for the covenant between Yahweh and his fathers. The Jeremian doctrine of individual responsibility and the teaching of a new covenant relation between Yahweh and the individual—these and other leading ideas appear to have been translated into the story of a united Israel.

The view here maintained, that the popular history is approximately of about the sixth century B.C., finds confirmation in Deuteronomy (*q.v.*). This book, which had an independent literary history before it became part of the Pentateuch, is distinguished by its appeal to men of Israel to secure the well-being of the community. Israel has come of age. There is a law, but it is within everyone's reach; and self-conscious covenanters decisively separating themselves from pagan neighbours are united to Yahweh who, while allotting objects of worship to other peoples, is himself Israel's God (*cf.* Deut. xii. 8, xiii. 6 *seq.*, xxvi. 16-19, xxx. 14). Apostasy and idolatry are to be mercilessly burnt out; religion and reward are organized, and upon the purity of the religion will depend nature's blessings and all prosperity. Whereas the earlier prophets condemn an errant nation and inculcate new ideas of Divine Holiness and Righteousness, Jeremiah, Ezekiel and Deuteronomy look forward, and a new reorganization is in process. In the archaic ideas of the Pentateuchal legislation is reflected a primitive stage of society, rather than a society with a long and continuous history behind it. There are signs of the inauguration of new conditions: in land laws (*cf.* Lev. xxv. 10), and in Ezekiel's curious, impracticable scheme for the division of the tribes (Ez. xlviii.). Hence, while the Pentateuch has always seemed to point naturally to the beginning of Israelite religion, all the weight of evidence appears to be against dating it in or about the Amarna Age, and in favour of the age at and after the collapse of the old Hebrew kingdoms, when new social and religious conditions were inaugurated, and led up to post-exilic Judaism.

13. **The New Jerusalem.**—The composite sources of the Pentateuch, when analysed, reflect some very important developments. Deuteronomy crystallising the work of the prophets, emphasizes Yahweh's disciplinary love for Israel and inculcates communal benevolence and humanity, to the poor and needy, and also to the *ger* or “client” (*not* “stranger”). Its passionate hatred

of false worship becomes concrete in the “Deuteronomic” history of Joshua's wars of conquest and extermination. But while the actual invasion and settlement of Israel seem to have been a more gradual process (Judges i.), the fanaticism which blazed forth in the fierce Maccabean struggles (§ 20) may well have manifested itself earlier, *e.g.*, after the fall of Jerusalem, when the land was exposed to invaders from the desert (*cf.* Ez. xi. 15, xxxiii. 24, xxxvi. 2-5, etc.). Moreover an Israel, a holy nation and a kingdom of priests (Ex. xix. 6), would need legitimate representatives. Yahweh's “holiness” must be preserved, and there is a transition from the prophets' ideas of spiritual and ethical holiness to the more ceremonial and ritual holiness of the later parts of the Pentateuch. A “nation of prophets” (Num. xi. 29) is too vague an aspiration, for “prophecy” is in itself a dubious phenomenon, as was frequently recognized. Yahweh's breath or spirit does not rest on all alike and in the story of Eldad and Medad, although 70 of the people's elders receive the spirit temporarily while in the Holy Tent, these two who remained behind but “prophesied” none the less, were—as a cautious interpolator explains—already on the register (v. 26). Again the Deutero-Isaiah (of the VIth century) views the return of exiles as a new Exodus, and in the new reorganization of the people the old traditions of an entry into a “promised land” would naturally have a new value. So, the story of the Wanderings in the Wilderness is that of the disciplining of a people: even the leaders Moses and Aaron cannot offend the “holiness” of Yahweh with impunity (Num. xx. 12). This absolute supremacy of Deity is characteristic of the heights of the religion (*cf.* Jeremiah's impassioned cry, xx. 7): Yahweh surpassed all that his most privileged prophets or priests might claim as his message or perform on his behalf. Yahweh was unfathomable—but he was Israel's own God (*see* § 14).

From an analysis of Deuteronomy and “Deuteronomic” literature it would seem that the prominence of Jerusalem is not an original feature of our narratives. A reforming movement which probably began in (north) Israel, in Samaria, and perhaps at the ancient sanctuary of Shechem with its “covenant god” (El-Berith), becomes specifically Judaeen, and the latest literature is hostile towards the brother people of the north. But foreign and pagan though the population of Samaria may have been, Jeremiah and Ezekiel regard it not without sympathy; both north and south are Yahweh's, and Ephraim is his first-born (Jer. xxxi. 9). The book of Deuteronomy in its earlier form is probably northern, of exilic date, and represents a Pan-Israelite standpoint (with R. H. Kennett). It is possible that the restoration of Judah and the Messianic zeal of Zerubbabel (520-516 B.C.) led to plans for the restoration of a Davidic empire with the inclusion of an unwilling Samaria. At all events, in the time of Nehemiah and Ezra—such is the natural order—Judah is desolate, surrounded by jealous neighbours, and the bitter divorce of Judah and Samaria implies an earlier period of close union. The importance which the temple and ritual of Jerusalem gain in the later literature stands in contrast to the indifference of the earlier great reforming prophets to the cultus. So, the history tells how the place which Yahweh shall choose—perhaps originally Shechem—proved to be Jerusalem, how David the head of its dynasty was preferred to the faithless Saul (contrast the praise in 2 Sam. i.), and how depraved priesthoods were ultimately supplanted by Zadok, the first priest of the temple built by David's son Solomon.

Thus, the old Hebrew religion was freed from earlier national limitations by the spiritual prophets. The way was prepared for a religion founded upon a common tradition. The old Israel (in the wide sense) became a Judaeen Israel based on Jerusalem, the north was rejected, and the true Israelite tribes of the north are supposed to be carried away centuries earlier. The history is artificially handled, with the result that Judah, the survivor of the true Israel, goes into exile, and Judah returns to a heathen land and restores the religion of which it had been the guardian. Jerusalem accordingly becomes the only centre of the only true religion, which was not to be found elsewhere (*cf.* the standpoint, 2 Chron. xiii. 8 *seq.* xxv. 7); and the old religion is thus transformed—under influences and circumstances which have been

concealed and forgotten—until the religion in its post-exilic form was believed to be that of the Mosaic age. And in days to come the religion of the late pre-Christian age was dated even from the pre-Mosaic period (see JUBILEES, BK. OF TESTAMENTS OF THE TWELVE PATRIARCHS). One is tempted to speak of the transition from the prophets to the priestly post-exilic religion as a retrogression. But Zoroastrianism, too, with its fine ethical universalism was followed by a priestly organization, and in the words of Israel Abrahams, "ritual may be machinery for applying principle; Law the means of making simple prophetic ideas work in the complex life of society" (in Peake, *People and Book*, p. 407).

14. **The Servant of Yahweh.**—These changes of epoch-making importance for the history of religion can be only imperfectly and hypothetically reconstructed, and in them a place must be found for the superb idealism of Is. xl. seq. and the "Servant of Yahweh." Hebrew monotheism here reaches its height, and the doctrine of Yahweh's absolute sovereignty is nowhere else so impressively and decisively set forth. There is no return to some past monotheism, for monotheising tendencies are to be estimated by their content and efficiency. From various writings (e.g., Jeremiah, Habakkuk, Zephaniah, Is. xl. seq., etc.), it can be seen that serious minds were utterly overwhelmed by the changing conditions in and about the sixth century. To this period (approximately) belong both blank scepticism—Yahweh may be safely ignored (Zeph. i. 12) and the crudest cults even of a totemistic character (Robertson Smith, *Religion of the Semites*, p. 628 seq.). When the "scheme of things" had been shattered and the disintegration of life and thought allowed room for new combinations of a higher and lower type, the conviction of Yahweh's supremacy over and immediate intervention in the world received new strength. It was not that—as in India—the world was illusion (*maya*), for the Semites were characteristically "this worldly"; but God was so real and immediate that the Israelite saw through the world unto his God. He would repudiate the Indian formula "that art thou"—*tat tvam asi*—the ultimate identity of man, God and the world; but would view the world as, so to speak, the sea that both severs man from and unites him to God. So a writer (or it may be a school) in a series of passages of unequalled force passes from the unique monotheistic teaching of Israel's God to the unique destiny of His people Israel. A "servant" had been anticipated, as the deliverer of an oppressed people; "the servant" had come and passed unrecognized, indeed rejected—not without apparent reason. New convictions arose of the efficacy of sacrifice and of Israel's function in history as a "servant," of an Israel within an Israel, and of an Israel as a light to the world. The interpretation of the biblical passages is, it is true, keenly disputed (see ISAIAH); but there is no doubt that the religious idealism of Israel here attained its zenith; a new era, it was felt, had been inaugurated; and the Deutero-Isaiah takes its proper place along with epoch-making religious events elsewhere—China (Lao-tse and Confucius), India (Mahavira and Buddha), Greece (Orphism, etc.); see G. F. Moore, *Hist. of Religions*, i. p. viii. seq.

So penetrating is the thought of the Deutero-Isaiah in its significance for Semitic self-consciousness and energy that all earlier conceptions of the special relation between Yahweh and Israel (e.g., Am. iii. 2) here reach their climax. Israel felt herself called for high office, and this required a preparatory purgation (cf. the call of Isaiah, ch. vi.; also Jer. xv. 19). The "servant" who bore the penalty of Israel's sins becomes an Israel, neither a "prophet" nor a "priest" people, but the sacrificial victim for the world. So naturally does the idea of the Servant lead on to the age when Jesus of Nazareth brought new conceptions of God and Man that it is only to be expected that some fateful events lie behind Is. xl.-lvi. But whereas later a Jewish sect had to cut itself off from Judaism in order to live, here Jewish history has thrown a veil over vicissitudes which must have had the profoundest influence—the fact that the chapters are preserved is itself significant—and the events and the leading figures in them have passed into oblivion.

15. **Post-Exilic Religion.**—Israel's kindred, Edom, Moab

and Ammon, like the great surrounding empires, fell in their day; even the Samaritans gradually ceased to enter into history. But Hebrew religion survived as Judaism. The "spirit of Yahweh" had breathed into the dead bones (Ez. xxxvii.), there had been another stage in evolution, and the new organism retains much that is old, though in a new form. For example, the old rite of CIRCUMCISION (*q.v.*) becomes exceptionally valuable, not as that of entry into the privileges of the social group, but as the participation, even of the young babe, in the covenant relation between Yahweh and Israel. The demands of the prophets for a "spiritual" circumcision (e.g., as a means of loving Yahweh, Deut. xxx. 6) were not lost, nor were the spiritual and ethical meanings they gave to ideas of righteousness and holiness forgotten. The EPHOD (*q.v.*), formerly denounced as idolatrous, becomes legitimate when confined to the legitimate priesthood. "Indeed, some of the priestly rites embody superstitious ideas of extremest antiquity, and are strangely pagan in their very form and enactment, yet out of all the heathen sting is removed through their adoption and promulgation by Yahweh" (Montefiore, *Rel. of the Ancient Hebrews*, p. 322).

Political aggrandisement is renounced: a last effort is charged against Nehemiah (vi. 6 sq.); but the High Priest has more than the glories of the old monarchy, and in the performance of his priestly office evoked scarcely less enthusiasm (Ecclus. i.). Yahweh lives in the very centre of Israel, amid the most meticulous ritual. The gulf between Yahweh and man is not ethical or spiritual (cf. Is. lvii. 15), but ceremonial; and the ideas of "sin," too, are prevalently material and ritualistic. The past crises had manifested the utter dependence of Israel upon an omnipotent Yahweh and the necessity of safeguarding his holiness. Hence "sin" and the need for Atonement (*q.v.*) are more conspicuous than before; and upon the Temple depend the ordinary needs of life. In the place of the "democratic" covenant between Yahweh and Israel and its material effects as in Deuteronomy (e.g., ch. xxviii.), the crops depend upon the temple-service (cf., Hag. i. 9, Mal. iii. 10, Zech. xiv. 17), and are endangered by a faithless priesthood (Mal. ii. 3). It was an old belief in a new dress. Israel's conviction of her meaning for the world fluctuated between a Prophet-people possessing the Truth and a Priest-people that controlled the Rites—a "suffering servant" was an alien conception. The enhanced supremacy of Yahweh exalted his people Israel and the officiating priesthood, and it is easy both to imagine what Hebrew religion was before the prophets gave it new form, and to understand how Rabbinical Judaism was convinced of the real benefits accruing to the world through Israel and her merits.

16. **Universalism.**—The Jews were only a small part of the mighty Persian empire which with a *lingua franca* (Aramaic), a well-organized and international administration, and the possession of the lofty ethical god of heaven, Ahura-Mazda, favoured an at least external unification of religion. The Persian kings treated other religions with tolerance and, for a century at all events, the Jews seem to have been especially favoured. But while the Jews found much in ethical Zoroastrianism to appreciate, there was the danger that in this cosmopolitan empire their Yahweh would be placed on a level with the pre-eminent gods of other peoples. To identify Yahweh with Ahura-Mazda might be easy; but the more the name of Yahweh was extended beyond the limits of Israel—to become "great among the nations" (Mal. i. 11), the graver the risk of weakening the uniquely intimate bond beyond Yahweh and Israel. Universalism had its dangers. Moreover, while the later prophets extol the future glory of Jerusalem, the resort of pilgrims and tribute-bearers, this extension of Yahwism was a sort of religious imperialism. Was the world ruled by Yahweh alone or through his vicegerents at Jerusalem? That Israel had a mission, she was convinced; but was she to carry the light among the nations, were the nations to see in her stirring history the principles of Divine Governance, or was Jerusalem to be the centre of tribute-bearing worshippers of Yahweh?

It is as a universal history that the Pentateuch opens, gradually narrowing its scope until the history of the Chosen People

begins with the choice of Abraham. The Pentateuch, which assumed its present form during the Persian period, was the character of Judaism, preserving the scattered Jews and giving them solidarity against attack. It was at once their pride and their gospel. But, including as it does both the priestly source, P, and the earlier and more popular J and E (see BIBLE: O.T. Crit.), it is a compromise, and that a compromise should ever have been determined is of outstanding interest, though what events lie behind it are unknown. Although the Pentateuch consequently covered a wide range of interest, it never precluded the further development of tradition and myth. Archaeological and other evidence testifies to the persistence of magic and superstition, and to the profound difference between the Pentateuch, and all it stood for, and the social religious conditions amid which the Jews lived. When the sage could declare that "the name of Yahweh was a strong tower" (Prov. xviii. 10), the use of the Holy Name for magical purposes by other classes of society is entirely intelligible; and while simple piety, as in the Psalms, knew how readily the troubled soul could call upon Yahweh's name, priestly religion surrounded Yahweh with a *cordon* of priests, and the utterance of the Name was avoided. Divine Transcendence characterises post-exilic religion, but Yahweh was completely *in* as well as completely *over* the world; and one of the problems of Yahwism was to keep between the extremes of an esoteric cult exclusively in priestly hands and a universalism which tended to deprive the Jew of all that made Yahweh his own God, and Israel his "peculiar treasure" (Mal. iii. 17).

17. **Intermediaries.**—Persian idealism is characteristically ethical and rational, and incompatible with Jewish theism; and when Artaxerxes II. (404–359 B.C.) officially recognized the cult of Anahita an old goddess of the Astarte-Ishtar type, and of Mithra, the mediating solar god (cf., Mitra above, § 4), his deference to popular religion would repel orthodox Judaism. It was, in any event, difficult to uphold a strictly monotheistic doctrine of Yahweh's supremacy, and even a Psalmist could praise Yahweh as greatest among other gods (Ps. lxxxvix. 6). Earlier, the angel or messenger of Yahweh was partly a temporary self-manifestation of Yahweh and partly an independent being (Ex. xxiii. 21, Judg. vi. 13–22, etc.), and whatever the sacred "Presence" (lit. "face" Is. lxiii. 9) and "Name" (Is. xlviii. 9, etc.), may have meant, in Phoenician the goddesses Tanit and Astarte are respectively styled Baal's "face" and "name." Various mediating terms come into use, e.g., "Holy Spirit" (see esp. Is. lxiii. 10 sq.), and the Rabbinic Memrā (Logos), Shekhinah, etc., but the popular tendency was to regard them as independent entities. So also the Zoroastrian Amesha-Spentas, the attributes, phases or qualities of Ahura-Mazda came to have independent existence.

Numerous angels and demons are met with in the Palestine of the Persian and Greek periods. They are usually ascribed to Persian influence, but the polytheism and demonism of ancient Babylonia and the figurines, amulets, etc., unearthed in Palestine show that these post-exilic beings, who are embodiments or causes of good and evil, etc., are the descendants of the Baals, demons, satyrs and other beings of the older times. To the Persian conception of tutelary beings, presiding *genii*, there are parallels in O.T. and later literature; and Michael (*q.v.*) the patron angel and champion of Israel, with whose fortunes Israel is bound up (Dan. x. 13, 20), goes back to archaic ideas. The fate of a tribe or people might depend upon the safety of the image of its god, or its king might be an effective and responsible representative; Yahweh himself appears as Israel's *go'el* or champion (in the Deutero-Isaiah). But he could not be at once the god of Israel alone and also god of all nations. On the other hand, Michael is the more anthropomorphic genius of Israel, a more national figure than the Persian Mithra, the contemporary universal all-seeing god of light and conqueror of evil. Later, in the Apocalypse of St. John, which preserves a number of old Hebraic elements, Michael fights against the dragon Satan, thus taking over the conflict which was otherwise waged by Marduk god of light in Babylonia, by Yahweh (Is. li. 9) and by Ahura-Mazda. See SATAN.

Ideas of conflict between light and darkness and good and evil were further developed. The more nearly Yahweh was brought

into the world the more distressing became the problem of evil. That God might send misfortune (*ra'*) as well as what was good (*tob*) was admitted; but when ethical ideas became more explicit, how could God be responsible for what offended ethical conscience? Already some old religious usages were a stumbling block, and human sacrifice, it had been said, either had never been ordained by Yahweh (Jer. vii. 31, xix. 5), or was a just penalty (cf. Ez. xx. 25; Ps. lxxxi. 12). Averse from speculation, the Jew found answer to all his tormenting questions in God. Job (*q.v.*) comes to learn that though the God who was so vindictively tormenting him was the God of the Universe, he could escape from the one to the other. Even if God cannot deliver man, yet He and not Nebuchadrezzar's image is the object of worship (Dan. iii. 18); and though He should fail to relieve man's needs, yet in the past He had shown His might, and Israel would still "rejoice in Yahweh, and joy in the God of his Salvation" (Hab. iii.). Here too was the solution of the problem of life after death. The prophets had attacked certain mourning-customs, resort to the dead and other practices, probably bound up with ancestor-cults, traces of which continue to persist. The archaeological evidence also shows that death was not believed to be the end of man's existence, though it cannot be definitely asserted that Egyptian influence in Palestine had introduced the Egyptian ideas of another life. The name of the dead could be kept alive by being "mentioned" and Yahweh had a "book of the living" (Ex. xxxii. 32 seq.; Ps. lxix. 28). But the older belief that a man's life was inextricably part of the more permanent life of the family or national group explains the care taken to preserve the group. This belief becomes more explicitly theistic when the emphasis is laid solely upon the relationship between the individual and Yahweh; and in the knowledge of this man neither fears nor speculates (cf. Ps. xxiii. 4, lxxiii. 25).

18. **Wisdom.**—On the one side, an internationalism wherein differences in religion could be reconciled or ignored, and, on the other, the conviction that God was a transcendent being, behind all things, led to the transition from theism to deism, and characteristic of the age of Greek influence is the so-called Wisdom Literature. Where the devotee found a single Divine Being, the sage found a single Law ruling all life, and this "wisdom" (*Hokmah*) itself becomes the centre of speculation. It is something almost mythological, self-existent; "got" by Yahweh before the creation of the world; the guide of rulers and the controller of morality and intelligence (Prov. viii.). It is the world-plan, causing things to be what they are; and Ben Sira (Ecclus. xxiv.) identifies it with the Jewish Law or Torah (*i.e.*, "direction"). The sages agree with the prophets that conduct is better than ritual. Morality pays, and the obvious offences (*e.g.*, adultery) bring obvious penalties. It is better to be poor than to be rich by illgotten gains, and pity for the poor brings a divine reward (Prov. xix. 17). Yahweh's blessings enrich a man (x. 22), and he treats men as they treat him (iii. 34). He is not to be blamed for the consequences of one's own folly (xix. 3); and no one can be harmed by an undeserved curse (cf. xxvi. 2). In the place of the inner life of the PSALMS (*q.v.*), the sages recommend prudence and sagacity; and the instructive and typical differences between personal piety and a moral philosophy find parallels outside Palestine, as far afield as the land of Lao-tse and Confucius. See further WISDOM (BOOK OF) and WISDOM LITERATURE.

19. **Apocalypse.**—An eternal world-order could be in the care of a righteous God (so the prophets), or it could be a moral order (so the sages); but it might also be viewed by the sceptic pessimistically as a pre-determined scheme from which there was no escape (cf. ECCLESIASTES). Distressful conditions and the failure of religion and philosophy to teach men to be at home in the world encouraged what is called APOCALYPTIC LITERATURE (*q.v.*). It came to be felt that the age of prophecy belonged to the past; and whereas the prophets worked to create history, apocalypse awaited it. The prophet moved in Yahweh's world and was filled with a living experience; whereas the apocalypticist placed a gulf between this world and the supernatural order: God had made two worlds (4 Ezra vii. 50). Yahweh did nothing without telling the prophets (Am. iii. 7), and there are stories of detailed proph-

ecies of a somewhat mechanical type (e.g., 2 Kings xiii. 2-5, xxiii. 16 *seq.*): but apocalypse foreshadows the working-out of a predetermined drama and reveals the future. It was an ancient belief that earthly things had a heavenly pattern, or that history had been written as "heavenly tablets" or could be deduced from the stars; and apocalypse is extraordinarily interesting for its ideas of history and destiny.

There was a feeling of impending, inevitable change, and that God would intervene in some spectacular or catastrophic way (as earlier, 1 Kings xix. 11 *seq.*). Things might be kept in reserve, to be brought forth at their time (*cf.* Is. xlviii. 6), and great changes could be betokened by a new name (Is. lxii. 2 *seq.*, *cf.*, Abram-Abraham, Jacob-Israel). Or the old might come again in a new form: a new Exodus, a new Elijah (Mal. iv. 5), or a new heaven and earth (*cf.*, Is. lxv. 17). Characteristic is the use of an old name for new teaching (*cf.*, Baruch, Enoch, Moses, etc., in the apocalyptic literature); truth is represented as unchanging, or as given from the first. Yahweh's world-plan pre-existed. He chose men from the womb to achieve his purposes, Jeremiah (i. 5), Cyrus (Is. xlv. 24), even the ideal Jacob-Israel (*ib.* v. 2), and at times there was some special supernatural intervention (Isaac, Gen. xvii., Samson, Judg. xiii.). Moreover, on the old group-idea a man was born of the group which lived on in the individuals; and he was so far pre-existent in that he carried on the life of the pre-existing group to which he belonged; or the "spirit (or breath)" of man comes from and returns to its eternal divine source (*cf.*, Eccles. xii. 7). More explicitly some part of man is believed to pre-exist (*cf.* Wisdom viii. 19 *sq.*), and according to 2 Enoch xxiii. 5, it is the soul. Ideas of man's place in the universe were indeed further developed, but Yahweh's purposes for either Israel or mankind had not yet been accomplished and were awaiting fulfilment.

20. **The Maccabaeian Age.**—Greek culture had penetrated deeply after the conquests of Alexander the Great (333 B.C.), though the paucity of historical material and the difficulty of dating the literature make it impossible to trace clearly the steps in the religious development. The stirring deeds of the Maccabees (*q.v.*) must have called forth and must have been shaped by literature of a national "prophetic" stamp, and many scholars have sought to discern Maccabaeian passages in the Old Testament, as apart from the book of Daniel (*q.v.*) evidently contemporary in its present form. Antiochus Epiphanes attempted to establish throughout his domain a single religion, symbolical of his own supremacy as the "god made manifest." Jews and Samaritans alike were threatened, and fought to maintain the supremacy of Yahweh against the Zeus Olympius and the Zeus Xenius to whom the daring king had dedicated the temples of Jerusalem and Gerizim respectively. Then the Jews, triumphant in their victories, became as of old fanatical nationalists, fighting both non-Jews and especially their less rigorous and Hellenizing brethren. Before long, John Hyrcanus is conquering the Samaritans, destroying their temple; the Idumaeans (the earlier Edomites) are forcibly Judaized, and a Jewish kingdom, almost Solomonic in its extent, flourishes between the end of the Seleucid and the beginning of the Roman period (141-63 B.C.). If the Davidic dynasty arose, as some evidence suggests, under South Palestinian or semi-Edomite auspices, it was through the Idumaeian Herods that the Jews entered upon their last period of prosperity under Roman patronage, and with all the dangers this meant for national Judaism. And the final catastrophe was witnessed—if not hastened—by the last of this strangely non-Jewish family, Agrippa II.

Meanwhile the Maccabaeian revolt against a semi-Greek and semi-Oriental life had purified the priesthood, and had given a fresh endorsement to Judaism shortly to become part of the Roman empire. It was a newly consolidated Judaism that now entered upon the western phase of its history, with a profounder conception of the part it was to play in universal history. The Jew with his Law, his traditions and his universal God, had something to offer a world from which, however, his own religion tended to keep him aloof. Judaism had already attracted the attention of the world, whether the curious Hecataeus of Abdera

(c. 290 B.C.), or his contemporary the anti-Jew historian Manetho. Judaism felt a world-call, and its proselytising zeal was favoured by the Romans, at least up to the time of Hadrian. Indeed there is a remarkable vigour throughout the Oriental religions, and many diverse tendencies of thought and a variety of sects characterise the eastern Roman empire at the birth of Christianity, primarily another Jewish sect. Besides certain striking ethical tendencies; and also the more impressive Messianic expectations (*see* MESSIAH), a Damascus body of Jewish covenanters, whose date unfortunately is seriously disputed, look for a "Teacher of Righteousness" who is to be followed by a Messiah not of Davidic origin. Their appreciation of the Law and of the Prophets combines Ezekiel's reforming Zadokite priesthood and Jeremiah's new covenant, and they testify to some reforming movement, whose further history is unknown, outside Judaea, and therefore in districts more remote from the narrower exclusive Judaism of Jerusalem. Similarly the book of Enoch (*q.v.*) appears to proceed from a North Palestinian (Galilaean) district, largely non-Jewish. *See* further, PHARISEES, SADUCEES, SCRIBES.

21. **The Last of the Prophets.**—Only the briefest account can here be given of the final act in the history of the old Hebrew religion. It is played upon a large stage amid the recurrence of the psychological characteristics of the VIth century B.C., viz., the intense anticipation of approaching cataclysmic changes (*cf.*, Ezek. xxxviii., *seq.*), and the need for a New Covenant (*cf.* Jer. xxxi.). The Galilaean Jesus of Nazareth, with uniquely heightened conceptions of God and of the individual is in the line of the great prophets. He demands a higher type of "righteousness," and a new life (*cf.*, the "new" heart and spirit of Ezek. xviii. 31); not ceremonial rectitude, but social ethical conduct (*cf.*, already Mic. vi. 8). As at an earlier inauguration of new conditions (§ 12) the individual's worth and his responsibilities are alike increased; there is a yoke, but it is easy (Matt. xi. 30, *cf.*, Deut. xxx. 11-14). Instead of a divinely-chosen Israel, or Davidic dynasty, or Aaronite priesthood, it is the individual who is sought after, as a lost sheep or coin. A new group-idea is formed; it is not that of a Jewish nation or church, or an inner Israelite circle or fellowship, but a Christian body or body of Christ. The real group is based (as with the prophets, § 6 end), not on its recognised members, but on Christ and what he demands of those that would be his, or—even unconsciously—do his will. The individual is the atom, but Jesus is "the individual," an ideal representative of humanity.

The old Israelite ideology finds its further development, especially the Deutero-Isaiah. Jesus is the Servant (*cf.* § 14), the Messiah, with a kingdom, though he is not a king. He is "Son of Man" (*i.e.*, a man); the title once applied expressively to Ezekiel the priest-prophet, watchman, representative and intermediary, later gains a deeper significance when used as a term of comparison for a glorified people of God, an Israel the possessor of a universal and everlasting kingdom (Dan. vii. 13). Again, in place of this ideal Israel, the Son of Man becomes, in the book of Enoch, a pre-existent Messiah, the vicegerent of the Almighty. Israel, as Yahweh's people, had had its representative king or priest, or prophet, or its Michael; but Israel was also the intermediary between God and the world. From the religious idealism of the Old Testament we pass to Christ as the representative and intermediary, and to the Christian body corresponding to the Israel of old.

Jesus and Paul share the uncompromising thoroughness and the iconoclasm of the great prophets. The old claims, doctrines and dogmas become secondary, e.g., the descent from Abraham and all it entailed (*cf.*, John the Baptist, Matt. iii. 9). Israel possessed no natural or inherited claims; for God had no favourites, absolute freedom of choice was his. A new doctrine of evolution was virtually introduced; Jewish branches are lopped off and the Gentiles grafted on, yet there is a real continuity. But the Gentiles must not boast for, like the prophets before him, Paul cannot conceive an ultimate separation of God and Israel; and, in a remarkable conception of Destiny, sees the ultimate "salvation" of Israel (Rom. xi. 26). The reign of Christ will lead up to the establishment of God's kingdom (1 Cor. xv. 24); like the Law

in its day and the present enmity of the Jews, all are part of a majestic world-process, as it had been in the day when He let Israel go into exile.

22. **The End.**—The Messiah came and went. It was the end of a complete cycle, from the beginning of sin to the act of redemption, from Death to Life, from the First Adam to the Second. But the end of one cycle was the beginning of another; and now there is much more that awaits "fulfilment," and a new finale before the end of things. Thus, there will be an anti-Christ, the embodiment of all evil, or a Dragon (in Rev. xiii., the late Hebraized form of an old myth), and there will be a false Messiah, a false God (2 Thess. ii. cf. Matt. xxiv. 5. 11, 23 seq.)—either stark evil or the more subtle evil of what looks like Religion but is its worst enemy. There is a perplexing and mutually inconsistent medley of ideas in early Christianity, due partly to the earlier experience of conflicts, and to earlier reflection upon world history, and partly the world of thought in which the new sect was reflecting upon the significance of Jesus.

Of peculiar value is the book of Revelation (see APOCALYPSE) where, with its traces of old Babylonian, Persian and other elements, the old Hebrew religion may be said to come to an end. The unique type of experience which characterizes the best Semites has here produced a final conception of world history which looks back to the Creation (Gen. i.) and forward to a New Heaven and Earth—the influence of the Deutero-Isaiah is perspicuous (see Rev. xxi. 1-8). All history is contained within Yahweh, who is First and Last (Is. xlv. 6), or within God, who is Alpha and Omega (Rev. i. 8, xxi. 6; said of Christ in i. 17, xxii. 13). So the Jewish-Christians feel themselves one with all that has gone before, and the unity and continuity of which they are conscious covers a remarkable development of ideas of God and man, yet a development so natural that there is a "fulfilment" far more impressive than the rather mechanical and artificial examples of "fulfilment" which the less sensitive and more prosaic minds sought and found, comparing the history of Israel with Jesus of Nazareth, a rather mechanical process which tended to obscure the fact that the close of one age was the beginning of another with another process of development. All the great stages in the development of religion in Palestine are part of the larger field of history and religion in which Palestine was involved. With the sweeping changes in South-west Asia during the eighth and following centuries a new type of religion was introduced, which broke with the old national religions and nature cults. Whatever be the cause, from China to Greece there was "a maximum in the tides of religion" a "simultaneity in progress and decline comparable to geological epochs of upheaval and subsidence" (G. F. Moore, *op. cit.* pp. vi.-ix.). The Hebrew prophets make the difference between an old and dying Egypto-Semitic world and the developments under Persian, Greek and Roman rule. The most significant period extends from Jeremiah to Jesus, or rather from Amos to Paul. The essential religion of Israel broke away from the old Hebrew, and was thereby preserved, and, as the curve proceeds, Judaism flies off at a tangent and uses the Old Testament in its own characteristic way (see MIDRASH, TALMUD). Yet when Judaism had first canonised the Pentateuch with its most diverse sources, and later fixed the canon of the whole of the Old Testament with all its extraordinary range of interest, it established a working rather than a systematic synthesis; it manifested an insight not less precious than that of the Western Christian Church when it determined to retain the Apocalypse, and so enabled the western mind to gain the profoundest conceptions of the nature of religious development and human progress.

HEBREWS, EPISTLE TO THE, a book of the New Testament, which in the oldest mss. bears no other title than

"To Hebrews," i.e., Christians of Jewish extraction. It was, however, directed to a definite circle of readers with whom the author had personal relations (xiii. 19, 23). Probably, then, the original limited address, or rather salutation, fell away when this appeal in letter form passed into the wider circulation which its contents merited.

Authorship.—In the earlier mss. it is anonymous; and the Roman Church, where the first traces of the epistle occur, about A.D. 96 (1 Clement), and which was in constant connection with provincial churches, was at a later date sure only that it was not by Paul (Euseb., *Eccl. Hist.*, iii. 3). The Alexandrine tradition, on the other hand, dwells on its affinities to Paul's thought. Origen implies that "the men of old" regarded it as Paul's. But he feels that the language is un-Pauline, though the "admirable" thoughts are not second even to Paul's. Thus he is led to the view that the ideas were orally set forth by Paul, but that the written form was due to some one giving free interpretation of his mind. According to some this was Clement of Rome; others named Luke; but the truth, says Origen, is known to God alone. (Euseb. vi. 25, cf. iii. 38). From the time of Origen the theory of Paul's own authorship became prevalent in the East. The earliest north African tradition preserved by Tertullian (*De pudicitia*, c. 20), but hardly invented by him, ascribed the epistle to Barnabas. Yet it was probably only an inference, as if this "word of exhortation" (xiii. 22) must needs be by the Son of Exhortation (Acts iv. 36; see BARNABAS). On the whole, then, the earliest traditions in East and West alike agree that it was not by Paul, but by one of his associates.

This is also the result reached by modern scholarship. Following the lead of Erasmus, Luther (who suggests Apollos) and Calvin added the decisive argument that Paul, who lays such stress on the fact that his gospel was not taught him by man (Gal. i.), could not have written Heb. ii. 3. And since the revival of the historical sense, more than a century ago, opinion has set irrevocably against Pauline authorship. Its type of thought is really different. The Jewish Law is viewed not as a code of "works of righteousness," as by Paul, but as a system of religious rites (vii. 11) shadowing forth the way of access to God in worship, of which the Gospel reveals the archetypal realities (ix. 1, 11, 15, 23 seq., x. 1 sqq., 19 sqq.). The Old and the New Covenants are related to one another as imperfect (earthly) and perfect (heavenly) forms and methods of salvation—differing in point of spiritual reality—each with its own type of sacrifice and priesthood. Thus the conception of Christ as High Priest emerges, for the first time, as a central point in Christianity. The Old Testament is cited after the Alexandrian version more exclusively than by Paul, even when the Hebrew differs. Nor is this accidental. The author was, in fact, a Hellenist who lacked knowledge of the Hebrew text, and derived his metaphysic and his allegorical method from the Alexandrian rather than the Palestinian schools. Yet the epistle has Pauline affinities, and can hardly have originated beyond the Pauline circle, to which it is related, not only by the author's friendship with Timothy (xiii. 23), but by many echoes of the Pauline theology, and even, it seems, of passages in Paul's epistles (see Holtzmann, *Einleitung in das N.T.*, 1892, p. 298). Everything turns, then, on internal criticism of the epistle, together with such personal allusions as it affords.

Readers.—As to its first readers, with whom the author stood in close relations (xiii. 19, 23, cf. vi. 10, x. 32-34), it used to be agreed that they were "Hebrews" or Christians of Jewish birth. But this can not be inferred simply from the fact that the epistle approaches Christian truth through Old Testament forms. That was the common method since the Jewish scriptures were the Word of God to all Christians alike. Still the exclusive use of the argument from Mosaism, as itself implying the Gospel of Jesus the Christ as final cause (*τέλος*), does favour the view that the readers were of Jewish origin. Further, there is no allusion to the incorporation of "strangers and foreigners" (Eph. ii. 19) with the people of God. Yet the readers are not to be sought in Jerusalem (see e.g., ii. 3), nor anywhere in Judaea. The whole Hellenistic culture of the epistle (let alone its language), and the personal references, notably that to Timothy in xiii. 23, are against any such view. Caesarea, as a city of mixed population and lying just

outside Judaea proper, would satisfy many conditions of the problem. Yet these might exist among other members of the Dispersion, like "the Jews of Asia" whose zeal for the Temple and the Mosaic ritual customs led to Paul's arrest in Jerusalem (Acts xix. 27 *seq.*, cf. 20 *seq.*). The dispersed Christian Jews, who kept in touch with the Temple by annual contribution to its services, would tend to continue their reliance on those services for the forgiveness of their recurring "sins of ignorance" even after the great initial Messianic forgiveness coming with faith in Jesus. Accordingly many of them, while placing their hope for the future upon Messiah and His return in power, might seek continuous cleansing of conscience in the old mediatorial system. In particular the annual Day of Atonement might be relied on, and that in proportion as the expected Parousia tarried and the first enthusiasm of a faith that was largely eschatological died away, while ever-present temptations pressed the harder as disappointment and perplexity increased.

Its Argument.—Such was the general situation of the readers, men who rested partly on the Gospel and partly on Judaism. For lack of a true theory as to the relation between the two, they were now drifting away (ii. 1) from effective faith in the Gospel, as being mainly future in its application, while Judaism was a very present, concrete, and impressive system of religious aids—to which also their sacred scriptures gave constant witness. The points at which it chiefly touched them may be inferred from the author's counter-argument, with its emphasis on the spiritual ineffectiveness of the whole Temple-system, its high-priesthood and its supreme sacrifice on the Day of Atonement. With passionate earnestness he sets over against these his constructive theory as to the efficacy, the heavenly yet unseen reality, of the definitive "purification of sins" (i. 3) and perfected access to God's inmost presence, secured for Christians as such by Jesus the Son of God (x. 9–22); and traces their moral feebleness and slackened zeal to want of progressive insight into the essential nature of the Gospel as a "new covenant," moving on a totally different plane of religious reality from the now antiquated covenant given by Moses (viii. 13).

The following plan of the epistle may help to make apparent the writer's theory of Christianity as distinct from Judaism, which is related to it as "shadow" to reality:

Thesis: The finality of the form of religion mediated in God's Son, i. 1–4.

- i. The supreme excellence of the Son's Person (i. 5–iii. 6), as compared with (a) angels, (b) Moses.
Practical exhortation, iii. 7–iv. 13, leading up to:
- ii. The corresponding efficacy of the Son's High-priesthood (iv. 14–ix.).
 - (1) The Son has the qualifications of all priesthood, especially sympathy.
Exhortation, raising the reader's thought to the height of the topic reached (v. 11–vi. 20).
 - (2) The Son as absolute high priest, in an order transcending the Aaronic (vii.) and relative to a Tabernacle of ministry and a Covenant higher than the Mosaic in point of reality and finality (viii., ix.).
 - (3) His Sacrifice, then, is definitive in its effects (*τετελειωκε*), and supersedes all others (x. 1–18).
- iii. Appropriation of the benefits of the Son's high-priesthood, by steadfast faith, the paramount duty (x. 19–xii.). More personal epilogue (xiii.).

As lack of insight lay at the root of their troubles, it was not enough simply to enjoin the moral fidelity to conviction which is three parts of Faith to the writer, who has but little sense of the mystical side of faith, so marked in Paul. There was need of a positive theory based on real insight, to inspire faith for more strenuous conflict with the influences tending to the apostasy from Christ, and so from "the living God," which already threatened some of them (iii. 12). Such "apostasy" was not a formal abjuring of Jesus as Messiah, but the subtler lapse involved in ceasing to rely on relation to Him for daily moral and religious needs, summed up in purity of conscience and peace before God (x. 19–23, xiii. 20 *seq.*). This "falling aside" (vi. 5, cf. xii. 12 *seq.*),

rather than conscious "turning back," is what is implied in the repeated exhortations which show the intensely practical spirit of the whole argument. These exhortations are directed chiefly against the dullness of spirit which hinders progressive moral insight into the genius of the New Covenant (v. 11–vi. 8). The antidote to such "profane" negligence (ii. 1, 3, xii. 12 *seq.*, 15–17) is an earnestness animated by a fully-assured hope, and sustained by a "faith" marked by patient waiting (*μακροθυμία*) for the inheritance guaranteed by Divine promise (x. 11 *seq.*). The outward expression of such a spirit is "bold confession," and mutual encouragement therein (iii. 6, 12 *seq.*); while the sign of its decay is neglect to assemble together for mutual stimulus, as if it were not worth the odium and opposition from fellow Jews called forth by a marked Christian confession (x. 23–25, xii. 3)—a very different estimate of the new bond from that shown by readiness in days gone by to suffer for it (x. 32 *seq.*). Their special danger, then, the sin which deceived (iii. 13) the more easily that it represented the line of least resistance (perhaps the best paraphrase of "the besetting sin" in xii. 1), was the exact opposite of "faith" as the author uses it, especially in the chapter of Old Testament illustrations, and of which Jesus Himself was at once the example and the inspiration (xii. 2 *seq.*). To quicken this by awakening deeper insight into the real objects of "faith," as these bore on their actual life, he develops his high argument on the lines already indicated.

The Special Situation.—Their situation was so dangerous just because it combined inward debility and outward pressure, both tending to the same result, viz., practical disuse of the distinctively Christian means of grace, as compared with those recognized by Judaism, and such conformity to the latter as would make the reproach of the Cross to cease (xiii. 13, cf. xi. 26). But the practical surrender of what was distinctive in their new faith meant a theoretic surrender of the value once placed on that element, when it was a living religious experience far in advance of what Judaism had given them (vi. 4 *seq.*, x. 26–29). This twofold infidelity, in thought and deed, God, the "living" God of progress from the "shadow" to the substance, would yet visit (x. 30 *seq.*, xii. 22–29). For it meant turning away from an appeal that had been known as "heavenly," for something inferior and earthly (xii. 25); from a call sanctioned by the incomparable authority of a greater than Moses and all media of the Old Covenant, even the Son of God. Thus the key of the whole exhortation is struck in the opening words, which contrast the piecemeal revelation "to the fathers," in the past, with the complete and final revelation to themselves in the last stage of the existing order, in a Son of transcendent dignity (i. 1 *seq.*, cf. ii. 1 *seq.*, x. 28 *seq.*, xii. 18 *seq.*). This goes to the root of their difficulty, ambiguity as to the relations of the old and the new elements in Judaeo-Christian piety, so that there was danger of the old overshadowing the new, since national Judaism remained hostile. At a stroke the author separates the two. There is *no use*, religiously, in falling back upon the old forms, in order to avoid the social penalties of a sectarian position within Judaism, when the secret of religious "perfection" or maturity (vi. 1, cf. the frequent use of the kindred verb) lies elsewhere. Hence the moral of his whole argument as to the two covenants, though it is formulated only incidentally amid final detailed counsels (xiii. 13 *seq.*) is to leave Judaism and adopt a purely Christian standing on the same footing with their non-Jewish brethren in the local church. For this the time was now ripe; and in it lay the true path of safety—eternal safety as before God, whatever man might say or do (xiii. 5 *seq.*). The obscure section xiii. 9 *seq.*, is to be taken as "only a symptom of the general retrogression of religious energy" (Jülicher) and not as bearing directly on the main danger of these "Hebrews."

External Occasion.—In trying further to define the readers addressed one must note the stress laid on suffering as part of the divinely appointed discipline of sonship (ii. 10, v. 8, xii. 7 *seq.*), and the way in which the analogy in this respect between Jesus, as Messianic Son, and those united to Him by faith, is set in relief. He is both the inspiring example for heroic faith in the face of unbelievers (xii. 3 *seq.*) and the mediator qualified

by experience of suffering to sympathize with His tried followers, and so to afford them moral aid (ii. 17 seq., v. 8 seq., cf. iv. 15). This means that suffering for Christianity, at least in respect of possessions (xii. 5 seq., cf. x. 34), was imminent for those addressed; and it seems as if they were mostly men of wealth and position (xiii. 1-6, vi. 10 seq., x. 34). Such would also possess a mental culture (cf. v. 11 seq.) capable of appreciating the form of an epistle "far too learned for the average Christian" (Jülicher), yet for which its author apologizes as inadequate (xiii. 22). It was now long since they themselves had suffered seriously for their own faith (x. 32 seq.) and the writer's impatience to hurry to their side implies that the crisis was both sudden and urgent.

Place and Author.—Many attempts have been made to identify the home of the Hellenistic Christians addressed in this epistle. For Alexandria little can be urged. "Alexandrine" idealism and allegorism was a mode of thought diffused throughout the Eastern Mediterranean, and the divergencies from Philo's spirit are as notable as the affinities (cf. Milligan, *ut infra* 203 sqq.). For Rome there is more to be said, in view of the reference to "them of Italy" (xiii. 23 seq.); and the theory has found many supporters. It usually contemplates a special Jewish-Christian house-church, like that meeting in the house of Prisca and Aquila (Rom. xvi. 5)—a chapter which some hold to have been part of a recension sent to Ephesus (see ROMANS, EPISTLE TO). Little, however, really points to Rome and a good deal points away from it. The words in xii. 4 "Not yet unto blood have ye resisted," would ill suit Rome after the Neronian "bath of blood" in A.D. 64 (as is usually held), save at a date too late to suit the reference to Timothy. Nor does early currency in Rome count for much, any more than do the words "they of Italy salute you." Read in the light of the reference to Timothy they rather suggest that he had been in prison in Rome and was about to return, possibly in the writer's company, to the region which was apparently the headquarters of both. Now this in Timothy's case, as far as we can judge, was Ephesus; and it is natural to ask whether it will not suit all the conditions of the problem. It suits those of the readers, as analysed above, a house-church which the gospel had reached as it had also the writer himself through certain hearers of the Lord (ii. 3), not necessarily apostles (cf. the Ephesian group of Acts xix. 1 sqq.). And it has the merit of suggesting to us as author the very person of all those described in the New Testament who seems most capable of the task, Apollos, the learned Alexandrian (Acts xviii. 24 sqq.), connected with Ephesus and with Paul and his circle (cf. 1 Cor. xvi. 12), yet having his own distinctive manner of presenting the Gospel (1 Cor. iv. 6). That Apollos visited Italy during Paul's imprisonment in Rome is a reasonable inference from Titus iii. 13 (see PAUL); and if so, it is quite natural that he should be there again about the time of Paul's martyrdom. With that event it is again natural to connect Timothy's imprisonment, his release from which our author records in closing; while the news of Jewish success in Paul's case would enhance any tendency among Asian Jewish Christians to shirk "boldness" of confession in fear of further aggression from their compatriots. On the chronology adopted in the article PAUL, this would yield as date for the epistle A.D. 61-62. The place of writing would be some spot in Italy ("they of Italy salute you") outside Rome, probably a port of embarkation for Asia, such as Brundisium.

Historical Significance.—Be this as it may, the epistle is of great importance, as reflecting a crisis inevitable in the development of the Jewish-Christian consciousness, when a definite choice between the old and the new form of Israel's religion had to be made, both for internal and external reasons. It seems to follow directly on the situation implied by the appeal of James to Israel in dispersion, in view of Messiah's winning-fan in their midst (James i. 1-4, ii. 1-7, v. 1-6 and especially v. 7-11). It may well be the immediate antecedent of that revealed in 1 Peter, an epistle which perhaps shows traces of its influence (e.g., in i. 2, "sprinkling of the blood of Jesus Christ"). It is also of high interest theologically, as exhibiting, along with affinities to several types of New Testament teaching (see STEPHEN), a type all its own, and one which has had much influence on later Christian thought

(cf. Milligan, ch. ix.). Indeed, it shares with Romans the right to be styled "the first treatise of Christian theology."

BIBLIOGRAPHY.—The older literature may be seen in F. Bleek, *Der Brief an die Hebräer* (1828-40); the more recent in G. Milligan, *The Theology of the Epistle of the Hebrews* (1899), a useful summary of all bearing on the epistle, and in the large New Testament Introductions (e.g., Jülicher or Moffatt). See also Hastings's *Dict. of the Bible*, the *Encycl. Biblica*, A. S. Peake in *The Century Bible* and J. Moffatt in the *Internat. Crit. Comm.* (J. V. B.)

HEBRIDES, THE, a group of islands off the west coast of Scotland, between 55° 35' and 58° 30' N. and 5° 26' and 8° 40' W., also known as the Western Isles. They have been broadly classified into Outer and Inner Hebrides, the Minch and Little Minch dividing one group from the other. The chief islands of the Outer Hebrides are Lewis-with-Harris (or Long Island), North Uist, Benbecula, South Uist, Barra, the Shiant, St. Kilda and the Flannan Isles, or Seven Hunters, about 20 m. N.W. of Gallon Head in Lewis. Of these the Lewis portion of Long Island, the Shiant and the Flannan belong to the county of Ross and Cromarty, and the remainder to Inverness-shire. The total length of this group, from Barra Head to the Butt of Lewis, is 130 m., the breadth varying from less than 1 m. to 30 miles. The Inner Hebrides include Skye, Small Isles (Canna, Sanday, Rum, Eigg and Muck), Coll, Tyree, Lismore, Mull, Ulva, Staffa, Iona, Kerrera, the Slate Islands (Seil, Easdale, Luing, Shuna, Torsay), Colonsay, Oronsay, Scarba, Jura, Islay and Gigha. Of these Skye and Small Isles belong to Inverness-shire, and the rest to Argyllshire. The Hebridean islands exceed 500 in number, of which less than one-fifth are inhabited. Of the inhabited islands ten belong to Ross and Cromarty, 46 to Inverness-shire, and 39 to Argyllshire, but of this total of 95 islands, 33 have a population of only ten persons, or fewer, each. The population of the Hebrides in 1921 numbered 70,517, of whom 8,797 spoke Gaelic only and 51,375 Gaelic and English. The most populous island is Lewis-with-Harris (32,283), and next to it are Skye (11,031), Islay (6,496) and Mull (3,389).

Most of the surface is moorland and mountain, with many lochs, and only a small proportion is under cultivation.

A geological division sometimes made, into the Gneiss islands and the Trap islands, is appropriate as concerns the Outer Hebrides, for these, together with Coll and Tyree, consist almost wholly of the Lewisian gneiss. The rocks of the other principal islands, however, differ greatly. Basalts have a wide extension in south-western Skye, in Canna, Eigg and Muck, in Mull, and in most of the small neighbouring islands such as Staffa, though the gneiss reappears in Iona. The complex geological structure of south-eastern Skye (q.v.) is in some measure repeated in Rum, where bold elevations of gabbro rise nearly 2,700 ft. from sea-level, surrounded in great part by a lower table-land of dark red Torridonian sandstone, which reappears farthest south in Colonsay and western Islay. The greater part of Islay and of Jura, however, consists of the Dalradian quartzites, schists and (in Islay) clay slates. The scenery of the islands, exposed as they are to the Atlantic storms, and generally treeless or nearly so, is wild and beautiful.

Potatoes and turnips are the only root crops that succeed, and barley and oats are grown in some of the islands. Sheep-farming and cattle-raising are carried on very generally, and, with the fisheries, provide the main occupation of the inhabitants, who profit also from tourists in summer. Industries include distilling, slate-quarrying and manufacture of tweeds, tartans and other woollens. There are extensive deer forests in Lewis-with-Harris, Skye, Mull and Jura. On many of the islands there are prehistoric remains and antiquities within the Christian period. The larger islands are all in regular communication with certain points of the mainland by means of steamers from Glasgow, Oban and Mallaig. The United Free Church has a strong hold on the people, but in a few of the islands the Roman Catholic church is still strong. In the larger inhabited islands schools have been established. The islands unite with the counties to which they belong in returning members to parliament.

History.—The Hebrides are mentioned by Ptolemy under the name of *Ἑβριδαί* and by Pliny under that of *Hebudes*, the mod-

ern spelling having, it is said, originated in a misprint. By the Norwegians they were called *Sudreyjar* or Southern Islands. The Latinized form was *Sodoresnes*, preserved to modern times in the title of the bishop of Sodor and Man. In the 6th century Scandinavian hordes poured in but in time adopted the language and faith of the islanders. The principal immigration took place towards the end of the 9th century in the early part of the reign of Harald Fairhair, king of Norway, and consisted of persons driven to the Hebrides, as well as to Orkney and Shetland, to escape from his tyrannous rule. Soon afterwards they began to make incursions against their mother-country, and on this account Harald fitted out an expedition against them, and placed Orkney, Shetland, the Hebrides and the Isle of Man under Norwegian government. The chief seat of the Norwegian sovereignty was Colonsay. About the year 1095 Godred Crovan, king of Dublin, Man and the Hebrides, died in Islay. His third son, Olaf, succeeded to the government about 1103, and the daughter of Olaf was married to Somerled, who became the founder of the dynasty known as Lords of the Isles. Many efforts were made by the Scottish monarchs to displace the Norwegians. Alexander II. led a fleet and army to the shores of Argyllshire in 1249, but died on the island of Kerrera. On the other hand, Haakon IV., king of Norway, at once to restrain his jarls and to keep in check the Scottish kings, set sail in 1263 on a great expedition, which, however, ended disastrously at Largs. Magnus, son of Haakon, concluded in 1266 a peace with the Scots, renouncing all claim to the Hebrides and other islands except Orkney and Shetland, and Alexander III. agreed to give him a sum of 4,000 merks in four yearly payments. It was also stipulated that Margaret, daughter of Alexander, should be betrothed to Eric, the son of Magnus, whom she married in 1281. She died two years later, leaving an only daughter, the Maid of Norway.

The race of Somerled continued to rule the islands, and from a younger son sprang the lords of Lorne, who took the patronymic of MacDougall. John MacDonald of Islay, who died about 1386, was the first to adopt the title of Lord of the Isles. He was married to a daughter of the earl of Strathearn, afterwards Robert II. His son, Donald of the Isles, was memorable for his unsuccessful rebellion in support of his claim to the earldom of Ross. Alexander, son of Donald, resumed the hereditary warfare against the Scottish crown; and in 1462 a treaty was concluded between Alexander's son and successor, John and Edward IV. of England, by which John, his son John, and his cousin Donald Balloch, became bound to assist King Edward and James, earl of Douglas, in subduing the kingdom of Scotland. In the reign of James V. another John of Islay resumed the title of Lord of the Isles, but was compelled to surrender the dignity. From the time of Bruce the Campbells had been gaining the ascendancy in Argyll. The MacLeans, MacNaughtons, MacLachlans, Lamonts and others had sunk before this favoured family. The lordship of Lorne was wrested from the MacDougalls by Robert Bruce, and their extensive possessions, with Dunstaffnage Castle, bestowed on the king's relative, Stewart, and his descendants, afterwards lords of Lorne. The MacDonalds of Sleat, direct representatives of Somerled, though driven from Islay and deprived of supreme power by James V., still kept a sort of insular state in Skye. There were also the MacDonalds of Clanranald and Glengarry (descendants of Somerled), with the powerful houses of MacLeod of Dunvegan and MacLeod of Harris, McNeill of Barra and MacLean of Mull, all turbulent rivals. James VI. made an abortive endeavour to colonize Lewis. William III. and Queen Anne attempted to subsidize the chiefs in order to preserve tranquillity, but the wars of Montrose and Dundee, and the Jacobite insurrections of 1715 and 1745, showed how futile were all such efforts. In 1748 the abolition of heritable jurisdictions, and the appointment of sheriffs in the different districts brought a great change, but led to high rents and emigration of tacksmen, or large tenants, to North America.

Sheep-farming on a large scale was next introduced, and the crofters were thrust into villages or barren corners of the land. The result was that, despite the numbers who entered the army or emigrated to Canada, the standard of civilization sank lower,

and the population multiplied in the islands. The people came to subsist almost entirely on potatoes and herrings; and in 1846, when the potato blight began its ravages, nearly universal destitution ensued. Temporary relief was given by employment on roads and other works; and, an emigration fund being raised, from 4,000 to 5,000 of the people in the most crowded districts were removed to Australia. The Crofters' Holdings Act was passed in 1886, and in the course of a few years some improvement was evident and has since been sustained. In recent years large numbers have emigrated to Canada.

HEBRON, a city of Palestine about 20 m. S.W. of Jerusalem and about 3,000 ft. above sea-level (mod. *El-Khalil*); pop. 16,500 (16,000 Muslims, 400 Jews). The town, no longer walled, with its stone houses, boasting curious vaulted cupolas, and narrow, winding streets, stands on the eastern slope of a shallow valley. It possesses a great many wells and two large reservoirs, one of which is generally identified with the Pool of Hebron (2 Sam. iv. 12). The town is divided into several quarters, and its chief industries are the manufacture of glass objects (lamps, bracelets, etc.), leather water-bottles from goats' skins, cotton goods. The Jews engage in wine-making and produce an excellent wine.

History.—Reputed one of the oldest cities (Num. xiii. 22), it was closely connected with Abraham in Bible tradition and was destroyed by Joshua (x. 26). From Hebron Joseph set out to seek his brethren at Shechem. David made it his home for a period. Absalom was born there and Abner was treacherously murdered at its gates by Joab. Absalom made the town the headquarters of his revolt. It was fortified by Rehoboam, captured from the Edomites by Judas Maccabaeus, and destroyed by the Romans. It revived under the Muslims and was a substantial town when captured by the Crusaders. It was occupied by British troops on Dec. 4, 1917.

Harām.—Hebron's chief interest is its Harām, an enclosure (198 ft. by 112 ft.) built over the traditional side of the cave of Machpelah. The ancient wall which encloses it rises to a height of 40 ft. (above that rise modern walls) and in construction and masonry closely resembles that of the Harām in Jerusalem. Within the enclosure is a mosque formerly a Crusaders' church (12th century), which in its turn was built on the site of a basilica of Justinian's time. Within the mosque are the cenotaphs of Abraham, Isaac, Jacob, Sarah, Rebecca and Leah, erected above the places where their tombs are presumed to be in the rocky cavern beneath. The cave itself has not been entered for more than 600 years. The mosque is approached by two flights of steps, but Jews are not permitted to go beyond the seventh step. At the fifth step there is an aperture believed to lead to the tomb of the patriarchs.

Flinders Petrie, *The Cave of Machpelah: Ancient Egypt* (1923), 105, seq.; P. J. Baldensperger, *Pal. Expl. Fund Quart. Statement*, 1915, seq. (on characteristics of people of Hebron). (E. Ro.)

HECATAEUS OF ABDERA (or of Teos) (fl. 4th century B.C.), Greek historian and Sceptic philosopher, accompanied Ptolemy I. Soter to Syria, and sailed up the Nile to Thebes with him. His travels were described in *Αἰγυπτιακά* and *Περὶ Τριεβορέων*, which were used by Diodorus Siculus.

Fragments in C. W. Müller's *Frag. hist. Graec.* and Diels: *Fragmente der Vorsokratiker*, vol. 2 (4th ed. 1922).

HECATAEUS OF MILETUS (6th–5th century B.C.), Greek historian and traveller, son of Hegesander, flourished during the time of the Persian invasion. He tried to dissuade the Ionians from revolt against Persia, and (Herodotus v. 36, 125) in 494, when they were obliged to sue for terms, he was one of the ambassadors to the Persian satrap, whom he persuaded to restore the constitution of the Ionic cities (Diod. Sic. x. 25). He is by some credited with a geographical work entitled *Ἦς περίοδος* ("Travels round the Earth"), in two books, one on Europe, the other on Asia, the account of Egypt being especially comprehensive; the book was accompanied by a map, based upon that of Anaximander. The authenticity of the work is, however, strongly

attacked by J. Wells in the *Journal of Hellenic Studies* (1909), xxix. pt. i. The only certainly genuine work of Hecataeus was the *Γενηλογίαι* or *Ἱστορίαι*, a systematic account of the traditions and mythology of the Greeks. He was probably the first to write a serious prose history and employ critical method to distinguish myth from fact, though he accepts Homer and the other poets as trustworthy authority. Herodotus, though he once at least (vi. 137) controverts his statements, is indebted to Hecataeus not only for facts, but also in regard to method and general scheme, but the extent of the debt depends on the genuineness of the *Γῆς περίοδος*.

See fragments in C. W. Müller, *Fragmenta historicorum Graecorum*, i.; or F. Jacoby, *Fragmente der griechischen Historiker* (1923), i., where references in ancient authors are quoted. H. Berger, *Geschichte der wissenschaftlichen Erdkunde der Griechen* (1903); E. H. Bunbury, *History of Ancient Geography*, i.; W. Mure, *History of Greek Literature*, iv.; H. Diels, *Herodotus und Hekataios in Hermes*, 1887; especially J. V. Prašek, *Hekataios als Herodots Quelle zur Geschichte Vorderasiens. Beiträge zur alten Geschichte* (Klio) (1904), iv. 193 seq., and J. Wells in *Journ. Hell. Stud.*, as above, and in reply, Max Carey in *J.H.S.* xxx.

HECATE (Gr. *Ἑκάτη*, "she who works from afar"), a goddess in Greek mythology. According to the generally accepted view, she was of Hellenic origin, but Farnell regards her as a foreign importation from Thrace, the home of Bendis, with whom Hecate had many points in common. She is not mentioned in the *Iliad* or the *Odyssey*, but in Hesiod (*Theogony*, 409) she is the daughter of the Titan Perses and Asterie. She is there represented as a mighty goddess, having power over heaven, earth and sea; hence she is the bestower of wealth and all the blessings of daily life. Hecate is frequently identified with Artemis, and both occasionally with the moon.

Later, Hecate is the chief goddess who presides over magic arts and spells; hence occasionally she is referred to as the mother of Circe, and her name is very common in charms. She is said to have been worshipped at Samothrace, and is closely connected with Demeter. Alone of the gods besides Helios, she witnessed the abduction of Persephone, and, torch in hand, assisted Demeter in her search for her daughter. On moonlight nights she was seen at the cross-roads (hence her name *τριοδῖτις*, Lat. *Trivia*), accompanied by ghosts and hell-hounds. There, on the last day of the month, eggs and fish were offered to her. Black puppies and she-lambs (black victims being offered to chthonian deities) were also sacrificed (Schol. on Theocritus ii. 12), the former unusual but not quite unparalleled victims in Greece. Pillars like the *Hermæ*, called *Hecataea*, stood, especially in Athens, at cross-roads and doorways, perhaps to keep away the spirits of evil. It is to be noted that Hecate plays little or no part in mythological legend.

In older times Hecate is represented as single-formed, clad in a long robe, holding burning torches; later she becomes *triformis*, "triple-formed," with three bodies standing back to back—probably in order to look all ways at once from the cross-road. In her six hands are various emblems.

See L. R. Farnell, *Cults of the Greek States*, ii. ch. xvi., xix.; Preller-Robert i., p. 321 et seq.; O. Gruppe, *Griechische Mythologie*, ii. p. 1,288 (1906); and the classical dictionaries.

HECATOMB, originally, perhaps, the sacrifice of a hundred victims, then of any large number. Hence in modern languages, the destruction of a multitude of living, or even of inanimate, things. (Gr. *ἐκατόμβη* from *ἐκατόν*, a hundred.)

HECKER, FRIEDRICH FRANZ KARL (1811–1888), German revolutionary, was born at Eichersheim in the Palatinate on Sept. 28, 1811, the son of a revenue official. On entering the Second Chamber of Baden in 1842, he at once began to oppose the government. A speech, denouncing the projected incorporation of Schleswig and Holstein with Denmark, delivered in the chamber of Baden on Feb. 6, 1845, spread his fame beyond the limits of his own state, and his popularity was increased by his expulsion from Prussia on the occasion of a journey to Stettin. In 1847 he became president of the *Volksverein*, where, with Struve, he drew up the Radical programme carried at the Liberal meeting held at Offenburg on Sept. 12, 1847 (entitled "thirteen claims put forward by the people of Baden"). In addition to the Offenburg programme, the *Sturmpetition* of March 1, 1848 de-

manded further far-reaching concessions. New demands were made at Offenburg on March 19, and Hecker moved a resolution in the preliminary parliament of Frankfurt that Germany should be declared a republic.

On April 12, Hecker and Struve sent a proclamation to the inhabitants of the *Seekreis* and of the Black Forest "to summon the people who can bear arms to Donaueschingen at mid-day on the 14th, with arms, ammunition and provisions for six days." They expected 70,000 men, but only a few thousand appeared. The troops of Baden and Hesse marched against them, under the command of General Friedrich von Gagern, and Hecker was defeated at Kandern (April 20). Hecker escaped to Switzerland, and in Sept. 1848 retired to the United States, where he had a farm near Belleville, (Ill.). During the second rising in Baden in the spring of 1849 he returned, and had got as far as Strasbourg when he had to retreat before the victories of the Prussian troops over the Baden insurgents.

After his return to America he fought in the Civil War as colonel of a regiment which he had himself got together on the Federal side in 1861 and 1864. In a famous festival speech at St. Louis in 1871 he expressed the enthusiasm of the German Americans for their newly-united fatherland. He received a less favourable impression during a journey he made in Germany in 1873. He died at St. Louis on March 24, 1881.

Hecker was very much beloved of all the German democrats. The song and the hat named after him (the latter a broad slouch hat with a feather) became famous as the symbols of the middle-classes in revolt. In America, too, he won great esteem, not only on political grounds but also for his personal qualities.

Hecker's works are: *Die Erhebung des Volkes in Baden für die deutsche Republik* (Baden, 1848); and *Reden und Vorlesungen* (Neerstadt a. d. H., 1872). See F. v. Weech, *Badische Biographien*, iv. (1891); L. Mathy, *Aus dem Nachlasse von K. Maty, Briefe aus den Jahren 1846–1848* (Leipzig, 1898).

HECKER, ISAAC THOMAS (1819–1888), American Roman Catholic priest, the founder of the "Paulist Fathers," was born in New York city, of German immigrant parents, on Dec. 18, 1819. When barely 12 years of age, he had to go to work, but he studied at every opportunity. Isaac was deeply religious, and remained so amid all the reading and agitating in which he engaged. He joined the Brook Farm movement, and remained in the colony for six months. Shortly after leaving it (in 1844) he was baptized into the Roman Catholic Church by Bishop McCloskey, of New York. In 1845 he was entered in the novitiate of the Redemptorists in Belgium, where he cultivated that spirit of lofty mystical piety which marked him through life.

Ordained a priest in London by Cardinal Wiseman in 1849, he returned to America, and worked until 1857 as a Redemptorist missionary. With all his mysticism, Isaac Hecker had the wide-awake mind of the typical American. He perceived that the missionary activity of the Catholic Church in the United States must remain to a large extent ineffective unless it adopted methods suited to the country and the age. Acting on this idea, and with the consent of his local superiors, Hecker went to Rome to beg of the Rector Major of his Order that a Redemptorist novitiate might be opened in the United States, in order to attract American youths to the missionary life. Though he took with him the strong approval of some members of the American hierarchy, the Rector Major expelled him from the Order for having made the journey to Rome without sufficient authorization. Hecker and four other American Redemptorists, however, were permitted by Pius IX. in 1858 to form the separate religious community of the Paulists. Hecker trained and governed this community until his death in New York City, on Dec. 22, 1888. He founded and was the director of the Catholic Publication Society, and the founder, and from 1865 until his death the editor, of the *Catholic World*; and wrote *Questions of the Soul* (1855), *Aspirations of Nature* (1857), *Catholicity in the United States* (1879), and *The Church and the Age* (1888).

HECKMONDWIKE, an urban district of the West Riding of Yorkshire, England, 8 m. S.E. of Bradford, on the L.M.S. railway. Pop. (1921), 9,023. It lies in the centre of the blanket and carpet manufacturing area. Coal is extensively mined in the

neighbourhood, and there are machine works, dye works and iron foundries.

HECTOGRAPH: see OFFICE APPLIANCES.

HECTOR, son of Priam and Hecuba and husband of Andromache. In Homer he is the chief Trojan warrior. He is an especial favourite of Apollo; and later poets even describe him as son of that god. After Achilles (*q.v.*) had killed him, Aphrodite and Apollo preserved his body from corruption and mutilation. Priam, guarded by Hermes, went to Achilles and prevailed on him to give back the body, which was buried with great honour. Hector was afterwards worshipped in the Troad and also at Tanagra.

HECUBA, in Greek HEKABE, principal wife of Priam, daughter of the Phrygian king Dymas (or of Cisseus, or of the river-god Sangarius). When Troy was captured and Priam slain, she was made prisoner by the Greeks. Her fate is told in various ways, most of which connect her with the promontory Cynossema ("dog's monument") on the Hellespont. According to Euripides (in the *Hecuba*), her youngest son Polydorus had been placed during the siege of Troy under the care of Polymestor, king of Thrace. When the Greeks reached the Thracian Chersonese on their way home she discovered that her son had been murdered, and in revenge put out the eyes of Polymestor and murdered his two sons. Later, she was turned into a dog, a legend variously rationalized by later writers, and her grave became a mark for ships (Ovid, *Metam.*, xiii. 399-575; Juvenal, x. 271 and Mayor's note).

HEDA, WILLEM CLAASZ (1594-1680), Dutch painter, born at Haarlem, was one of the first Dutchmen to devote himself to the painting of still life. He showed considerable skill and taste in arranging and colouring chased cups and beakers and tankards. Nothing is so appetizing as his "luncheon," with rare comestibles set out upon rich plate, oysters—seldom without the cut lemon—bread, champagne, olives and pastry, painted in a silvery tone against a grey background. Most of Heda's pictures are on the European continent, notably in the galleries of Aix-la-Chapelle, Amsterdam, Dresden, Ghent, The Hague, Karlsruhe, Munich, Paris, Rotterdam, Schwerin and Vienna (Liechtenstein gallery). There is one picture by him in the National Gallery, London.

HEDGE BINDWEED (*Calystegia Sepium* or *Convolvulus Sepium*), a perennial vine of the morning-glory family, Convolvulaceae (*q.v.*), called also great bindweed, bracted bindweed and Rutland beauty. It is cosmopolitan in temperate regions, occurring in hedges and thickets in the British Isles and found in North America from Newfoundland to British Columbia and southward to Mexico. It is an extensively trailing or high-climbing vine, 3 ft. to 10 ft. high, with slender-stalked, spear-shaped leaves, and handsome solitary flowers, pink with white stripes or entirely white, about 2 in. long. The species varies greatly and several races have been described, some of which are cultivated for ornament. (See CALYSTEGIA.)

HEDGEBOT or **HAYBOTE**, an ancient legal term signifying the right of a tenant or copyholder to take or cut wood for specific purposes such as the repairs of fences and hedges for the upkeep of the premises as distinguished from the cutting of timber for building purposes, which constituted an infringement of the law. See HAY.

HEDGEHOG or **URCHIN**, a mammal of the order Insectivora (*q.v.*), remarkable for its armature of spines and short tail. The upper jaw is longer than the lower, the snout long and flexible, and the claws long but weak. The animal is about roin. long, the lower surface covered with hairs of the ordinary character. Its eyes are small. The brain is remarkable for its low development. The hedgehog has the power of rolling itself up into a ball, from which the spines stand out in every direction; these are sharp, hard, and elastic, and form an efficient defence. The moment it is touched, or even hears the report of a gun, it rolls itself up by the action of four muscles beneath the skin, while the same contraction effects the erection of the spines.

Though insectivorous, the hedgehog will devour mice, frogs, and toads, as well as plants and fruits. It also eats snakes, and its fondness for eggs has provoked the enmity of game-preservers; and there is no doubt it occasionally attacks leverets and game-

chicks. It does not emerge from its retreat during daylight, unless urged by hunger or by the necessities of its young. During winter it passes into a state of hibernation (*q.v.*), rolled up in a nest of dry leaves. In July or August the female brings forth four to eight young; at birth the spines, which in the adult are black in the middle, are white and soft, but soon harden, attaining their full size in the succeeding spring.

THE COMMON HEDGEHOG (ERINACEUS EUROPAEUS)

The hedgehog, known scientifically as *Erinaceus europaeus*, is the type of the family *Erinaceidae*, and extends over nearly the whole of Europe. The genus is represented by about a score of species, ranging over Europe, Asia, except the Malay countries, and Africa, being also found at 6,000 to 8,000 ft. above sea-level.

HEDGE NETTLE (*Stachys palustris*), a plant of the mint family (Labiatae), called also marsh-wound wort, marsh-betony and clown's-heal, widely distributed in Europe, Asia and North America. It is an erect, slender, sometimes slightly branched, rather stiffly hairy perennial, 1 ft. to 4 ft. high, with lance-shaped, more or less sharply toothed leaves and purplish flowers, about 3/4 in. long, borne usually in elongated clusters at the end of the stem but sometimes also in the upper axils of the leaves. This plant is typically representative of the botanical genus *Stachys*, embracing some 200 species, found (except in Australia) widely throughout the world; four others, including the wound-wort (*S. Betonica*), occur in Great Britain, and some 20 others are native to the United States and Canada.

HEDGE-SPARROW (*Prumella modularis*), a small, brown-backed European bird somewhat smaller than the house sparrow. It is a common resident and partial migrant in Great Britain and in most parts of Europe. The hedge-sparrow, or dunnoek, which has nothing in common with the house sparrow but the name, has a short, musical, high-pitched song, constantly repeated. The cuckoo often chooses the hedge-sparrow as foster-mother for its young, as recorded by Shakespeare in *King Lear*. Like many small English birds, the hedge-sparrow has been successfully introduced into New Zealand.

HEDGING, a method by which traders in commodities may partially or entirely insure themselves against loss from price fluctuations. The technique of hedging is the making at about the same time of two contracts of an opposite though corresponding nature; one a genuine trade contract in a cash or "spot" market, with a view to obtaining a dealer's ordinary trade profit, the other an insurance or protective contract in the speculative or "futures" market which counteracts loss (and profit) on the first transaction through price fluctuations. In simpler terms, hedging is the offsetting of a cash transaction in a commodity by an opposite and corresponding future transaction; one involves a purchase and the other a sale. Both involve the same amount of commodity.

The following example illustrates the execution of a simple "hedge" by a grain elevator in a local growers' market. A grain elevator operator in Walhalla, N.D., buys on Oct. 5, 5,000 bu. of No. 1 red winter wheat at \$1.33 per bushel from a farmer who has delivered the wheat to the elevator, knowing that the cash price of this grade of wheat in Minneapolis, Minn., is \$1.41, 8 cents more than he pays the farmer. This difference is represented by the elevator operator's estimate of a cost of 5 cents per bushel to pay the freight from Walhalla to Minneapolis, and by the necessary margin for handling wheat of 3 cents per bushel. The purpose of hedging is to protect the trade profit in this case, a portion of the 3 cent margin. Consequently, the elevator operator telegraphs a broker holding a membership on the Minneapolis Chamber of Commerce to execute on the exchange a sale of 5,000 bu. of wheat for delivery in December. The price of a December futures contracts on Oct. 5, in Minneapolis, is \$1.45. The difference between the cash price of \$1.41 and the December futures price of \$1.45 is theoretically what the price difference should be to cover the cost (storing, insuring, etc.) of carrying the wheat

from October to December. With the conclusion of the future sale on the Minneapolis exchange, the elevator operator has protected his cash wheat either entirely or partially from loss (and profit) because of price fluctuations. As soon, however, as the trade transaction is terminated by a cash sale, the future sale, at that moment a "short" sale, must also be terminated, *i.e.*, covered by a purchase on the exchange. Both contracts are entered into at about the same time, and both must be terminated at about the same time if the hedger wishes to avoid pure speculation.

Hedging is actually a relatively imperfect form of price insurance because of its dependency upon a parallel movement of cash (spot) and future prices. In practice, the future price often runs at a discount under the cash (spot) price for long periods and the more distant delivery months often sell at a discount under the near months. Moreover, occasionally the future price may run at a premium over the cash (spot) price, a premium higher than is necessary to cover carrying charges. In such cases speculative losses and profits are possible. Hedging has reached its highest stage in the cases of wheat and cotton. It is used, however, in trading in rubber and in many other commodities, wherever organized commodity exchanges permit future contracts under careful regulation.

HEDIN, SVEN (1865–), Swedish explorer, was born in Stockholm on Feb. 19, 1865. He was educated at Stockholm high school, and Uppsala university, and later studied in Berlin and Halle. In 1885–86 he travelled through Persia and Mesopotamia, and in 1890 was attached to King Oscar's Embassy to the shah of Persia. In the same year he visited Khurasan and Turkestan and reached Kashgar in 1891. His travels in Tibet placed him in the first rank of modern Asiatic explorers. Between 1893 and 1897 he travelled across the Asiatic continent from Orenburg by the Ural over the Pamirs and the plateau of Tibet to Peking. During two other expeditions (1899–1902, 1906–08) he made valuable additions to the scientific knowledge of these tracts and explored specially the sources of the Sutlej and the Brahmaputra. In 1902 he became a Swedish noble, and in 1909 the Indian Government invested him with the K.C.I.E. In 1923 he travelled round the world, through the United States, Mongolia and Russia. He is one of the 18 members of the Swedish Academy.

Sven Hedin's writings include: *Journey through Persia and Mesopotamia and the Caucasus* (1887); *Journey through Khorasan and Turkestan* (1892–93); *Through Asia* (1898); *Central Asia and Tibet* (1903); *Adventures in Tibet* (1904); *Scientific Results of a Journey in Central Asia 1899–1902* (8 vol., 1904–07); *Transhimalaya* (3 vol., 1909–12); *Overland to India* (2 vol., 1910); *Bagdad, Babylon, Nineveh* (1917); *To Jerusalem* (1917); *Southern Tibet* (12 vol., 1917–22); *Eine Routenaufnahme durch Ostpersien* (2 vol., 1918–24); *My Life as an Explorer* (1926).

HEDJAZ: see HEJAZ.

HEDON, a municipal borough of the East Riding of Yorkshire, England, 5½ m. E. of Hull by L.N.E. railway, and 2 m. from the river Humber. Pop. (1921), 1,321. It was formerly a considerable port. According to tradition the men of Hedon received a charter of liberties from King Aethelstan. The manor is not mentioned in Domesday, but it formed part of the lordship of Holderness which William the Conqueror granted to Odo, count of Albemarle. An undated charter of Henry II. contains the first certain evidence of settlement. By it, the king granted to William, count of Albemarle, free borough rights in Hedon so that his burgesses might hold of him as freely and quietly as the burgesses of York or Lincoln held of the king. An earlier charter, granted to the inhabitants of York, shows that these rights included a trade gild and freedom from many dues, not only in England, but also in France. In 1200, King John granted a confirmation of these liberties, and for this second charter the burgesses themselves paid 70 marks. In 1272, Henry III. granted to Edmund, earl of Lancaster, and Avelina his wife, then lord and lady of the manor, the right of holding a fair at Hedon on the eve, day, and morrow of the feast of St. Augustine and for five following days. After the countess' death the manor came to the hands of Edward I. In 1280 it was found by an inquisition that the men of Hedon "were few and poor" and that if the town were demised at a feorm rent, the town might improve. Apparently the grant was not made until 1346. Hedon was incorporated by Charles II. in

1661, and James II. in 1680 gave the burgesses and the charter, granting, among other privileges, that of holding two extra fairs. The church of St. Augustine is of Early English, Decorated and Perpendicular styles. The west front is particularly fine, and there is a lofty clerestory. Bricks are manufactured, but the population is mainly agricultural. The corporation possesses a remarkable mace of 15th century workmanship.

HEDONISM, in ethics, a general term for all theories of conduct in which the criterion is pleasure of one kind or another (Gr. *ἡδονή*, pleasure, from *ἡδύς*, sweet, pleasant). Hedonistic theories of conduct have been held from the earliest times, though they have been by no means of the same character. Moreover, hedonism has, especially by its critics, been very much misrepresented owing mainly to two simple misconceptions. In the first place hedonism may confine itself to the view that, as a matter of observed fact, all men do in practice make pleasure the criterion of action, or it may go further and assert that men ought to seek pleasure as the sole human good. The former statement takes no view as to whether or not there is any absolute good: it merely denies that men aim at anything more than pleasure. The latter statement admits an ideal, *summum bonum*—namely, pleasure. The second confusion is the tacit assumption that the pleasure of the hedonist is necessarily or characteristically of a purely physical kind; this assumption is in the case of some hedonistic theories a pure perversion of the facts. Practically all hedonists have argued that what are known as the "lower" pleasures are not only ephemeral in themselves but also productive of so great an amount of consequent pain that the wise man cannot regard them as truly pleasurable; the sane hedonist will, therefore, seek those so-called "higher" pleasures which are at once more lasting and less likely to be discounted by consequent pain. It should be observed, however, that this choice of pleasures by a hedonist is conditioned not by "moral" (absolute) but by "prudential" (relative) considerations.

The earliest and the most extreme type of hedonism is that of the Cyrenaic School as stated by Aristippus, who argued that the only good for man is the sentient pleasure of the moment. Since (following Protagoras) knowledge is solely of momentary sensations, it is useless to try, as Socrates recommended, to make calculations as to future pleasures, and to balance present enjoyment with disagreeable consequences. The true art of life is to crowd as much enjoyment as possible into every moment. This extreme or "pure" hedonism regarded as a definite philosophic theory practically died with the Cyrenaics, though the same spirit has frequently found expression in ancient and modern, especially poetical, literature.

The confusion already alluded to between "pure" and "rational" hedonism is nowhere more clearly exemplified than in the misconceptions which have arisen as to the doctrine of the Epicureans. To identify Epicureanism with Cyrenaicism is a complete misunderstanding. It is true that pleasure is the "supreme good" of Epicurus, but his conception of that pleasure is profoundly modified by the Socratic doctrine of prudence and the eudaemonism of Aristotle. The true hedonist will aim at a life of enduring rational happiness; pleasure is the end of life, but true pleasure can be obtained only under the guidance of reason. Self-control in the choice of pleasures with a view to reducing pain to a minimum is indispensable. "Of all this, the beginning, and the greatest good, is prudence." The negative side of Epicurean hedonism was developed to such an extent by some members of the school (see HECESIAS) that the ideal life is held to be rather indifference to pain than positive enjoyment. This pessimistic attitude is far removed from the positive hedonism of Aristippus.

Between the hedonism of the ancients and that of modern philosophers there lies a great gulf. Practically speaking ancient hedonism advocated the happiness of the individual: the modern hedonism of Hume, Bentham and Mill is based on a wider conception of life. The only real happiness is the happiness of the community, or at least of the majority: the criterion is society, not the individual. Thus we pass from Egoistic to Universalistic hedonism, to Utilitarianism and to Social Ethics, especially in relation to the broad theories of evolution. These theories are

confronted by the problem of reconciling and adjusting the claims of the individual with those of society. One of the most important contributions to the discussion is that of Sir Leslie Stephen (*Science of Ethics*), who elaborated a theory of the "social organism" in relation to the individual. The end of the evolution process is the production of a "social tissue" which will be "vitally efficient." Instead, therefore, of the criterion of "the greatest happiness of the greatest number," Stephen has that of the "health of the organism." Life is not "a series of detached acts, in each of which a man can calculate the sum of happiness or misery attainable by different courses." Each action must be regarded as directly bearing upon the structure of society.

See ETHICS, CYRENAICS, EPICURUS, etc. J. S. Mackenzie, *Manual of Ethics* (1924); J. Watson, *Hedonistic Theories*, 1895.

HEDRICK, ULYSSES PRENTISS (1870—), American horticulturist, was born at Independence, Ia., on Jan. 15, 1870. He graduated in 1893 at Michigan Agricultural college in which he was assistant horticulturist in 1893-95. He was professor of horticulture in Oregon Agricultural college in 1895-97, in Utah Agricultural college in 1897-99 and in Michigan Agricultural college in 1899-1905. In 1905 he became horticulturist at the New York agricultural experiment station, Geneva, where he conducted extensive researches in fruit growing, especially in pomology, in which he became a prominent American authority.

His works include *Grapes of New York* (1908); *Plums of New York* (1910); *Cherries of New York* (1915); *Peaches of New York* (1917); *Manual of American Grape Growing* (1919); *Sturdevant's Notes on Edible Plants* (1919); *Cyclopedia of Hardy Fruits* (1921); *The Pears of New York* (1922); *Systematic Pomology* (1925); and *Small Fruits of New York* (1925).

HEEL, (1) that part of the foot in man which is situated below and behind the ankle; by analogy, the calcaneal part of the tarsus in other vertebrates. The heel proper in digitigrades and ungulates is raised off the ground and is commonly known as the "knee" or "hock," while the term "heel" is applied to the hind hoofs; (2) to turn over to one side, especially of a ship.

HEEM, JAN DAVIDSZ VAN or **JOHANNES DE** (c. 1600-c. 1683), Dutch painter. He was, if not the first, certainly the greatest painter of still life in Holland. Sometimes de Heem painted alone, sometimes in company with men of his school, Madonnas or portraits surrounded by festoons of fruit or flowers. At one time he signed with initials, at others with Johannes, at others again with the name of his father joined to his own. De Heem entered the guild of Antwerp in 1635-36, and became a burgher of that city in 1637. He steadily maintained his residence till 1667, when he moved to Utrecht, where traces of his presence are preserved in records of 1668, 1669 and 1670. It is not known when he finally returned to Antwerp, but his death is recorded in the guild books of that place. A very early picture, dated 1628, in the gallery of Gotha, bearing the signature of Johannes in full, shows that de Heem at that time was familiar with the technical habits of execution peculiar to the youth of Albert Cuyp. Out of 100 pictures or more to be met with in European galleries scarcely eighteen are dated.

CORNELIUS DE HEEM, the son of Johannes, was in practice as a flower painter at Utrecht in 1658, and was still active in his profession in 1671 at The Hague. His pictures are not equal to those of his father, but they are all well authenticated, and most of them in the galleries of The Hague, Dresden, Cassel, Vienna and Berlin. In the Staedel at Frankfurt is a fruit piece, with pot-herbs and a porcelain jug, dated 1658; another, dated 1671, is in the museum of Brussels. **DAVID DE HEEM**, another member of the family, entered the guild of Utrecht in 1668 and that of Antwerp in 1693. The best piece assigned to him is a table with a lobster, fruit and glasses, in the gallery of Amsterdam; others bear his signature in the museums of Florence, Leningrad and Brunswick.

HEEMSKERK, JOHAN VAN (1597-1656), Dutch poet, born at The Hague on Feb. 27, 1597. He was educated at Bayonne, and at the university of Leyden in 1617. In 1621 he went abroad. He settled in 1640 in Amsterdam where he died on Feb. 27, 1656. For the last 12 years of his life he sat in the upper house of the States-general. Heemskerk published volumes of poems—*Minnekunst* (1622), *Minnepfligt* (1625), and *Minnekunde* (1628); but

he is famous as the author of *Batavische Arcadia* (1647), which introduced the Italian pastoral romance into Holland.

HEEMSKERK, MARTEN JACOBZ (1498-1574), Dutch painter, sometimes called Van Veen, was born at Heemskerk in Holland in 1498, and apprenticed by his father, a small farmer, to Cornelisz Willemsz, a painter at Haarlem. He worked under Jan Lucadaz at Delft and under Jan Schoreel at Haarlem, where he formed what is known as his first manner, a quaint and *gauche* imitation of the florid style brought from Italy by Mabuse and others. He then made a tour of northern and central Italy, before going to Rome, where he spent some years. With Antonio da San Gallo, Battista Franco and Francesco Salviati, he was selected to decorate the triumphal arches erected at Rome in April 1536 in honour of Charles V. On his return to the Netherlands he settled at Haarlem, where he became (1540) president of his gild, and married twice. In 1572 he left Haarlem for Amsterdam, where he died on Oct. 1, 1574.

The works of Heemskerk are very numerous. The portrait of the artist's father in the metropolitan Museum of Art at New York, "Adam and Eve," and "St. Luke painting the Likeness of the Virgin and Child" in the gallery of Haarlem, and the "Ecce Homo" in the museum of Ghent, are characteristic works of the period preceding Heemskerk's visit to Italy. An altar-piece executed for St. Laurence of Alkmaar in 1538-41, and composed of at least a dozen large panels, now in the cathedral of Linköping in Sweden, a "Crucifixion" executed for the Riches Claires at Ghent (now in the Ghent museum) in 1543, and the altar-piece of the Drapers Company at Haarlem, now in the gallery of The Hague, and finished in 1546, are representative of his style after his return from the south. Other notable works are in the galleries of Brussels, Brunswick, Cologne, Delft, Dresden, The Hague, Hampton Court, Haarlem, Petrograd, Prague, Rennes, Turin and Vienna. His self portrait is in the Fitz-William museum at Cambridge.

HEEMSKERK, THEODORE (1852—), Dutch statesman, son of Jan Heemskerk, entered the second chamber in 1888. He made a great reputation as a juriconsult, and as prime minister (1908-13) reserved for himself the portfolio of the interior. He was minister of justice (1918-25) and minister of State (1926). He was the leader in the second chamber of the Anti-Revolutionary Party.

HEER, JAKOB CHRISTOPH (1859-1925), a prolific Swiss novelist, was born at Töss (Canton Zürich) on July 17, 1859, and died on Aug. 20, 1925. After some experience as a teacher and editor, he devoted himself to writing romantic novels, chiefly dealing with Swiss life and marked by a certain old-fashioned air that enhances rather than detracts from their charm. His best work is *An Heiligen Wassern* (1898), but the most popular is *Der König der Bernina* (1900), describing an interesting phase in the history of the Grisons. His *Tobias Heider* (1923) is autobiographical in character.

See G. H. Heer, *Jakob Christoph Heer* (1927).

HEER, OSWALD (1809-1883), Swiss geologist and naturalist, was born at Nieder-Utzwyl in Canton St. Gallen on Aug. 31, 1809. He was a pioneer in palaeobotany, distinguished for his researches on the Miocene flora. In 1851 he became professor of botany in the University of Zurich, and he directed his attention to the Tertiary plants and insects of Switzerland. For some time he was director of the botanic garden at Zurich. He died at Lausanne on Sept. 27, 1883.

He published *Flora Tertiaria Helvetiae* (3 vols., 1855-59); *Die Urwelt der Schweiz* (1865), and *Flora fossilis Arctica* (1868-83).

HEEREN, ARNOLD HERMANN LUDWIG (1760-1842), German historian, was born on Oct. 25, 1760 at Arbergen, near Bremen. He studied history at Göttingen, and was appointed (1787) one of the professors of philosophy, and then of history in his university. He died at Göttingen on March 6, 1842. Heeren regarded the states of antiquity from an altogether fresh point of view; he examined their economic relations, their constitutions, their financial systems, and thus threw a new light on the development of the ancient world. He was a pioneer in the movement for the economic interpretation of history.

Heeren's chief works are: *Ideen über Politik, den Verkehr, und den Handel der vornehmsten Völker der alten Welt* (2 vols., Göttingen, 1793-96; 4th ed., 6 vols., 1824-26; Eng. trans. 1833); *Geschichte des Studiums der klassischen Literatur seit dem Wiederaufleben der Wissenschaften* (2 vols., Göttingen, 1797-1802; new ed., 1822); *Geschichte der Staaten des Altertums* (Göttingen, 1799; Eng. trans., Oxford, 1840); *Geschichte des europäischen Staatensystems* (Göttingen, 1800; 5th ed., 1830; Eng. trans., 1834); *Versuch einer Entwicklung der Folgen der Kreuzzüge* (Göttingen, 1808; French trans. 1808), a prize essay of the Institute of France. With Friedrich August Ukert (1780-1851) he founded the famous historical collection, *Geschichte der europäischen Staaten* (Gotha, 1819 seq.), which reached its 158th volume in 1925, and contributed many papers to learned periodicals.

HEERLEN, a town of Holland in the south of the province of Limburg, on the railway from the German frontier at Alsdorf westward and northward, and about 5 m. from the frontier. Pop. (1927), 40,719. The town is one of the centres of the coalfield which is now in course of development.

HEFELE, KARL JOSEF VON (1809-1893), German Catholic theologian, was born at Unterkochen, Württemberg, on March 15, 1809, and was educated at Tübingen, where, after minor appointments elsewhere, in 1840 he became professor of Church history and patristics. From 1842 to 1845 he sat in the National Assembly of Württemberg, and in 1869 was enthroned bishop of Rottenburg. Previous to this appointment, Hefele had won a reputation for scholarship by his early publications: *Patrum Apostolicorum Opera* (1839, 4th ed. 1855), *Der Kardinal Ximenes* (1844, 2nd ed. 1851), *Chrysostomuspostille* (1845, 3rd ed. 1857) and particularly the *Conciliengeschichte* (1855-74, 2nd ed. 1873-90, Eng. trans. 1871). He opposed the decrees of papal infallibility at the Vatican Council of 1870, and did not submit until 1871. Hefele died at Rottenburg on June 6, 1893.

See Herzog, *Realencyklopädie*, and *Dict. de Théol. catholique*.

HEGEL, GEORG WILHELM FRIEDRICH (1770-1831), German philosopher, was born at Stuttgart on Aug. 27, 1770. His father was a revenue officer. He learned the elements of Latin from his mother before he went to the Stuttgart grammar school, where he remained until he was 18. As a schoolboy he made a collection of extracts, alphabetically arranged, comprising annotations on classical authors, passages from newspapers, treatises on morals and mathematics from the standard works of the period. In this way he absorbed raw materials for elaboration. Yet as evidence that he was not merely receptive we have essays already breathing that admiration of the classical world which he never lost.

In the autumn of 1788 he entered at Tübingen as a student of theology; but he showed no interest in theology and his sermons were a failure. He found more congenial reading in the classics, on the advantages of studying which his first essay was written. After two years he took the degree of Ph.D., and in the autumn of 1793 received his theological certificate, stating him to be of good abilities, but of middling industry and knowledge, and especially deficient in philosophy. As a student, his elderly appearance gained him the title "Old man," but he took part in the walks, beer-drinking and love-making of his fellows. He gained most from intellectual intercourse with his contemporaries, among whom were J. C. F. Hölderlin and Schelling. With Hölderlin Hegel learned to feel for the old Greeks a love which grew stronger as the semi-Kantianized theology of his teachers more and more failed to interest him. With Schelling like sympathies bound him. They both protested against the political and ecclesiastical inertia of their native state, and adopted the doctrines of freedom and reason.

On leaving college, he became a private tutor at Bern and lived in intellectual isolation. He compiled a systematic account of the fiscal system of the canton Bern; but the main factor in his mental growth came from his study of Christianity. Under the impulse given by Lessing and Kant he turned to the original records of Christianity, and attempted to construe for himself the real significance of Christ. He wrote a life of Jesus, in which Jesus was simply the son of Joseph and Mary. He did not stop to criticize as a philologist, and ignored the miraculous. He asked for the secret contained in the conduct and sayings of this man which made him the hope of the human race. Jesus appeared as revealing the

unity with God in which the Greeks in their best days unwittingly rejoiced, and as lifting the eyes of the Jews from a lawgiver who metes out punishment on the transgressor, to the destiny which in the Greek conception falls on the just no less than on the unjust.

The interest of these ideas is twofold. In Jesus Hegel finds the expression for something higher than mere morality: he finds a noble spirit which rises above the contrasts of virtue and vice into the concrete life, seeing the infinite always embracing our finitude, and proclaiming the divine which is in man and cannot be overcome by error and evil, unless man close his eyes and ears to the godlike presence within him. In religious life, in short, he finds the principle which reconciles the opposition of the temporal mind. But, secondly, the general source of the doctrine that life is higher than all its incidents is of interest. He does not free himself from the current theology either by rational moralizing like Kant, or by bold speculative synthesis like Fichte and Schelling. He finds his panacea in the concrete life of humanity.

During these years Hegel kept up a slack correspondence with Schelling and Hölderlin. Schelling, already on the way to fame, kept Hegel abreast with German speculation. Both of them were intent on forcing the theologians into the daylight, and grudged them any aid they might expect from Kant's postulation of God and immortality to crown the edifice of ethics. Meanwhile, Hölderlin in Jena had been following Fichte's career with an enthusiasm with which he infected Hegel. Towards the close of his engagement at Bern, Hegel had received hopes from Schelling of a post at Jena. Fortunately his friend Hölderlin, now tutor in Frankfurt, secured a similar situation there for Hegel in the family of Herr Gogol, a merchant (Jan. 1797). The new post gave him more leisure and the society he needed.

About this time he turned to questions of economics and government. He had studied Gibbon, Hume and Montesquieu in Switzerland. We now find him making extracts from the English newspapers on the Poor-Law Bill of 1796; criticizing the Prussian land laws, promulgated about the same time; and writing a commentary on James Steuart's *Inquiry into the Principles of Political Economy*. Here, as in criticisms of Kant's ethical writings, Hegel aims at correcting the abstract discussion of a topic by treating it in its systematic interconnections. Church and state, law and morality, commerce and art are reduced to factors in the totality of human life, from which the specialists had isolated them. But the best evidence of Hegel's attention to contemporary politics is two unpublished essays—one of them written in 1798, "On the Internal Condition of Württemberg in Recent Times, particularly on the Defects in the Magistracy," the other a criticism on the constitution of Germany, written, probably, not long after the peace of Lunéville (1801). Both essays are critical rather than constructive.

His old interest in the religious question reappears, but in a more philosophical form. Starting with the contrast between a natural and a positive religion, he regards a positive religion as one imposed upon the mind from without, not a natural growth crowning the round of human life. A natural religion, on the other hand, was not, he thought, the one universal religion of every clime and age, but rather the spontaneous development of the national conscience varying in varying circumstances. A people's religion completes and consecrates their whole activity: in it the people rises above its finite life in limited spheres to an infinite life where it feels itself fulfilled. Even philosophy with Hegel at this epoch was subordinate to religion; for philosophy must never abandon the finite in the search for the infinite. Soon, however, Hegel adopted a view according to which philosophy is a higher mode of apprehending the infinite than even religion.

At Frankfurt, meanwhile, the philosophic ideas of Hegel first assumed proper philosophic form. In a ms. of 102 quarto sheets, of which the first three and the seventh are wanting, there is preserved the original sketch of the Hegelian system, so far as the logic and metaphysics and part of the philosophy of nature are concerned. The third part of the system—the ethical theory—seems to have been composed afterwards; it is contained in its first draft in another ms. of 30 sheets.

Circumstances soon put Hegel in the way to complete these out-

lines. His father died in January 1799; and the slender sum which Hegel received as his inheritance, 3,154 gulden (about £260), enabled him to think once more of a studious life. Hegel arrived at Jena in January 1801. An end had already come to the brilliant epoch at Jena, when the romantic poets, Tieck, Novalis and the Schlegels made it the headquarters of their fantastic mysticism, and Fichte turned the results of Kant to the service of revolutionary ideas. Schelling was the main philosophical lion of the time; and in some quarters Hegel was spoken of as a new champion summoned to help him in his struggle with the more prosaic continuators of Kant. Hegel's first performance seemed to justify the rumour. It was an essay on the difference between the philosophic systems of Fichte and Schelling, tending in the main to support the latter. Still more striking was the agreement shown in the *Critical Journal of Philosophy*, which Schelling and Hegel wrote conjointly during the years 1802-03. So latent was the difference between them at this epoch that in one or two cases it is not possible to determine by whom the essay was written. The dissertation by which Hegel qualified for the position of *Privatdozent* (*De orbitis planetarum*) was probably chosen under the influence of Schelling's philosophy of nature.

Hegel's lectures, in the winter of 1801-02, on logic and metaphysics were attended by about eleven students. Later, in 1804, we find him with a class of about thirty, lecturing on his whole system; but his average attendance was rather less. Besides philosophy, he once at least lectured on mathematics. As he taught, he was led to modify his original system, and notice after notice of his lectures promised a text-book of philosophy—which, however, failed to appear. Meanwhile, after the departure (1803) of Schelling from Jena, Hegel was left to work out his own views. Besides philosophical studies, where he now added Aristotle to Plato, he read Homer and the Greek tragedians, made extracts from books, attended lectures on physiology, and dabbled in other sciences. On his own representation at Weimar, he was in February 1805 made a professor extraordinarius, and in July 1806 drew his first and only stipend—100 thalers. At Jena, though some of his hearers became attached to him, Hegel was not a popular lecturer.

Of the lectures of that period there still remain considerable notes. The language often had a theological tinge (never entirely absent), as when the "idea" was spoken of, or "the night of the divine mystery," or the dialectic of the absolute called the "course of the divine life." Still his view was growing clearer, and his difference from Schelling more palpable. Both Schelling and Hegel stand in a relation to art, but while the aesthetic model of Schelling was found in the contemporary world where art was a special sphere and the artist a separate profession in no intimate connection with the age and nation, the model of Hegel was found rather in those works of national art in which art is not a part but an aspect of the common life, and the artist is not a mere individual but a concentration of the passion and power of beauty in the whole community.

On the 14th of October 1806 Napoleon was at Jena. Hegel, like Goethe, felt no patriotic shudder at the national disaster, and in Prussia he saw only a corrupt and conceited bureaucracy. Writing to his friend F. J. Niethammer (1766-1848) on the day before the battle, he speaks with admiration of the "world-soul," the emperor, and with satisfaction of the probable overthrow of the Prussians. Hegel's fortunes were now at the lowest ebb. Yet at this time he finished and published his first great work, the *Phänomenologie des Geistes* (1807). He was, therefore, glad to become editor of the *Bamberger Zeitung* (1807-1808). Of his editorial work there is little to tell; no leading articles appeared in his columns. It was not a suitable vocation, and he gladly accepted the rectorship of the Aegidien-gymnasium in Nuremberg, a post which he held from December 1808 to August 1816. As a teacher and master Hegel inspired confidence in his pupils, and maintained discipline without pedantic interference in their associations and sports.

In 1811 Hegel married Marie von Tucher (twenty-two years his junior) of Nuremberg. The marriage was entirely happy. His income amounted at Nuremberg to 1,500 gulden (£130) and a

house; at Heidelberg, as professor, he received about the same sum; at Berlin about 3,000 thalers (£300). Two sons were born to them; the elder, Karl, became eminent as a historian. The younger, Immanuel, was born on Sept. 24, 1816.

In 1812 appeared the first two volumes of his *Wissenschaft der Logik*, and the work was completed by a third in 1816. This work, in which his system was for the first time presented in what, with a few minor alterations, was its ultimate shape, brought him the offer of three professorships, at Erlangen, Berlin and Heidelberg. He accepted the post at Heidelberg, whence Fries had just gone to Jena (October 1816). Among his pupils was Hermann F. W. Hinrichs (*q.v.*), to whose *Religion in its Inward Relation to Science* (1822) Hegel contributed an important preface.

In 1817 he brought out the *Encyklopädie d. philos. Wissenschaften im Grundrisse* for use at his lectures. It is the only exposition of the Hegelian system as a whole which we have direct from Hegel's own hand. Besides this work he wrote two reviews for the Heidelberg *Jahrbücher*—the first on F. H. Jacobi, the other a political pamphlet entitled a *Criticism on the Transactions of the Estates of Württemberg in 1815-1816*.

In 1818 Hegel accepted the renewed offer of the chair of philosophy at Berlin, vacant since the death of Fichte. His influence upon his pupils, and his solidarity with the Prussian government, gave him a position such as few professors have held.

In 1821 Hegel published the *Grundlinien der Philosophie des Rechts*. It is a theory in which the fundamental principles of law, morality and social institutions (municipal and political) are shown to be connected stages in the logical evolution of rational will. It is animated by the idea that whatever is real is rational, and whatever is rational is real. His theory was not a mere formulation of the Prussian state. It is inspired by an overpowering sense of the value of organization—a sense that liberty can never be dis severed from order, that a vital interconnection between all the parts of the body politic is the source of all good.

During his thirteen years at Berlin Hegel's whole soul seems to have been in his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. We can form an idea of them from the shape in which they appear in his published writings. Those on *Aesthetics*, on the *Philosophy of Religion*, on the *Philosophy of History* and on the *History of Philosophy*, have been published by his editors, mainly from the notes of his students, under their separate heads; while those on logic, psychology and the philosophy of nature are appended in the form of illustrative and explanatory notes to the sections of his *Encyklopädie*. During these years hundreds of hearers from all parts of Germany, and beyond, came under his influence. His fame was carried abroad by eager or intelligent disciples.

Three courses of lectures are especially the product of his Berlin period: those on aesthetics, the philosophy of religion and the philosophy of history. In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert-rooms and picture-galleries. At these Hegel became a frequent and appreciative visitor and made extracts from the art-notes in the newspapers. In his holiday excursions, the interest in the fine arts more than once took him out of his way to see some old painting. This familiarity with the facts of art, though neither deep nor historical, gave a freshness to his lectures on aesthetics, which, as put together from the notes of 1820, 1823, 1826, are in many ways the most successful of his efforts.

The lectures on the philosophy of religion are another application of his method. Shortly before his death he had prepared for the press a course of lectures on the proofs for the existence of God. In his lectures on religion he dealt with Christianity, as in his philosophy of morals he had regarded the state. On the one hand he turned his weapons against the rationalistic school, who reduced religion to the modicum compatible with an ordinary worldly mind. On the other hand he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology. His middle way attempts to show that the dogmatic creed is the rational development of what was implicit in religious feeling. To do so, of course, philosophy becomes the

interpreter and the superior.

A Hegelian school began to gather. The flock included intelligent pupils, empty-headed imitators, and romantic natures who turned philosophy into lyric measures. Opposition and criticism only served to define more precisely the adherents of the new doctrine. Hegel himself grew more and more into a belief in his own doctrine as the one truth for the world. He was in harmony with the government, and his followers were on the winning side. Though he had soon resigned all direct official connection with the schools of Brandenburg, his real influence in Prussia was considerable, and as usual was largely exaggerated in popular estimate. In the narrower circle of his friends his birthdays were the signal for congratulatory verses. In 1831 he received a decoration from Frederick William III. In 1830 he was rector of the university.

One of the last literary undertakings in which he took part was the establishment of the Berlin *Jahrbücher für wissenschaftliche Kritik*, in which he assisted Edward Gans and Varnhagen von Ense. The aim of this review was to give a critical account, certified by the names of the contributors, of the literary and philosophical productions of the time, in relation to the general progress of knowledge. The journal was not solely in the Hegelian interest; and more than once, when Hegel attempted to domineer over the other editors, he was met by vehement and vigorous opposition.

The revolution of 1830 was a great blow to him, and the prospect of democratic advances almost made him ill. His last literary work, the first part of which appeared in the *Preussische Staatszeitung*, was an essay on the English Reform Bill of 1831. It contains primarily a consideration of its probable effects on the character of the new members of parliament, and the measures which they may introduce. In the latter connection he enlarged on several points in which England had done less than many continental states for the abolition of monopolies and abuses.

In 1831 cholera first entered Europe. Hegel and his family retired for the summer to the suburbs, and there he finished the revision of the first part of his *Science of Logic*. At the beginning of the winter session he returned to his house in the Kupfergraben. On Nov. 14, after one day's illness, he died of cholera and was buried, as he had wished, between Fichte and Solger.

Hegel in his class-room was neither imposing nor fascinating. You saw a plain, old-fashioned face, without life or lustre—a figure which had never looked young, and was now prematurely aged; the furrowed face bore witness to concentrated thought. Sitting with his snuff-box before him, and his head bent down, he looked ill at ease, and kept turning the folios of his notes. His utterance was interrupted by frequent coughing; every sentence came out with a struggle. The style was no less irregular. Sometimes in plain narrative the lecturer would be specially awkward, while in abstruse passages he seemed specially at home, rose into a natural eloquence, and carried away the hearer by the grandeur of his diction. (For bibliography see s.v. HEGELIAN PHILOSOPHY.)

HEGELIAN PHILOSOPHY. Hegelianism is confessedly one of the most difficult of all philosophies. Every one has heard the legend which makes Hegel say, "One man has understood me, and even he has not." He abruptly hurls us into a world where old habits of thought fail us. In three places, indeed, he has attempted to exhibit the transition to his own system from other levels of thought; but in none with much success. In the introductory lectures on the philosophy of religion he gives a rationale of the difference between the modes of consciousness in religion and philosophy (between *Vorstellung* and *Begriff*). In the beginning of the *Encyklopädie* he discusses the defects of dogmatism, empiricism, the philosophies of Kant and Jacobi. In the first case he treats the psychological aspect of the difference; in the latter he presents his doctrine less in its essential character than in special relations to the prominent systems of his time. The *Phenomenology of Spirit*, called "the first part" of his system, suffers from a different fault. It is not an introduction—for the philosophy which it was to introduce was not then fully elaborated. Even to the last Hegel had not so externalized his system as to treat it as something to be led up to by gradual steps. His philosophy

was not one aspect of his intellectual life, to be contemplated from others; it was the ripe fruit of concentrated reflection, and had become the one all-embracing form and principle of his thinking. More than most thinkers, his thought was moulded by the influences of his time and the lessons of history.

The Phenomenology.—The *Phenomenology* is the picture of the Hegelian philosophy in the making—at the stage before the scaffolding has been removed from the building. For this reason the book is at once the most brilliant and the most difficult of Hegel's works—the most brilliant as a speculative effort constructed to combine the abstract record of a logical evolution with the real history of an intellectual growth; the most difficult because, instead of treating the rise of intelligence (from its first appearance in contrast with the real world to its final recognition of its presence in, and rule over, all things) as a purely subjective process, it exhibits this rise as wrought out in historical epochs, national characteristics, forms of culture and faith, and philosophical systems. The theme is identical with the introduction to the *Encyklopädie*; but it is treated in a very different style. From all periods of the world—from mediæval piety and stoical pride, Kant and Sophocles, science and art, religion and philosophy—regardless of mere chronology, Hegel gathers in the vineyards of the human spirit the grapes from which he crushes the wine of thought. The mind coming through a thousand phases of mistake and disappointment to a sense and realization of its true position in the universe—such is the drama which is subjectively Hegel's own history, but is represented objectively as the process of the spiritual history of humanity reproduced in himself. The *Phenomenology* stands to the *Encyklopädie* somewhat as the dialogues of Plato stand to the Aristotelian treatises. It contains almost all his philosophy—but irregularly and without due proportion.

The *Phenomenology* treats of the attitudes of consciousness towards reality under the six heads of consciousness, self-consciousness, reason (*Vernunft*), spirit (*Geist*), religion and absolute knowledge. The native attitude of consciousness towards existence is reliance on the evidence of the senses; but a little reflection is sufficient to show that the reality attributed to the external world is as much due to intellectual conceptions as to the senses, and that these conceptions elude us when we try to fix them. If consciousness cannot detect a permanent object outside it, so self-consciousness cannot find a permanent subject in itself. It may, like the Stoic, assert freedom by holding aloof from the entanglements of real life, or like the sceptic regard the world as a delusion, or finally, as the "unhappy consciousness" (*Unglückliches Bewusstsein*), may be a recurrent falling short of a perfection which it has placed above it in the heavens. But in this isolation from the world, self-consciousness has closed its gates against the stream of life. The perception of this is reason. Reason convinced that the world and the soul are alike rational observes the external world, mental phenomena, and specially the nervous organism, as the meeting ground of body and mind. But reason finds much in the world recognizing no kindred with her, and so turning to practical activity seeks in the world the realization of her own aims. Reason abandons her efforts to mould the world, and is content to let the aims of individuals work out their results independently, only stepping in to lay down precepts for the cases where individual actions conflict, and to test these precepts by the rules of formal logic.

So far we have seen consciousness on one hand and the real world on the other. The stage of *Geist* reveals the consciousness no longer as critical and antagonistic but as the indwelling spirit of a community, as no longer isolated from its surroundings but the union of the single and real consciousness with the vital feeling that animates the community. This is the lowest stage of concrete consciousness—life, and not knowledge; the spirit inspires, but does not reflect. It is the age of unconscious morality, when the individual's life is lost in the society of which he is an organic member. But increasing culture presents new ideals, and the mind, absorbing the ethical spirit of its environment, gradually emancipates itself from conventions and superstitions. This *Aufklärung* prepares the way for the rule of conscience, for the moral view of the world as subject of a moral law. From the moral

world the next step is religion; the moral law gives place to God. But the idea of Godhead, too, as it first appears, is imperfect, and has to pass through the forms of nature-worship and of art before it reaches a full utterance in Christianity. Religion in this shape is the nearest step to the stage of absolute knowledge; and this absolute knowledge—"the spirit knowing itself as spirit"—is not something which leaves these other forms behind but the full comprehension of them as the organic constituents of its empire; "they are the memory and the sepulchre of its history, and at the same time the actuality, truth and certainty of its throne." Here, according to Hegel, is the field of philosophy.

The preface to the *Phenomenology* signalled the separation from Schelling—the adieu to romance. Philosophy is to be the science of the actual world—it is the spirit comprehending itself in its own externalizations and manifestations. The philosophy of Hegel is idealism, but it is an idealism in which every idealistic unification has its other face in the multiplicity of existence. It is realism as well as idealism, and never quits its hold on facts. Nature and mind in the Hegelian system—the external and the spiritual world—have the same origin, but are not co-equal branches. The natural world proceeds from the "idea," the spiritual from the idea and nature. Reality, independent of the individual consciousness, there must be; reality, independent of all mind, is an impossibility. At the basis of all reality, whether material or mental, there is thought. Thought in its primary form, when in all its parts completed, is what Hegel calls the "idea." But the idea, though fundamental, is in another sense final, in the process of the world. It only appears in consciousness as the crowning development of the mind. Only with philosophy does thought become fully conscious of itself in its origin and development. Accordingly the history of philosophy is the presupposition of logic, or the three branches of philosophy form a circle.

Logic.—The exposition or constitution of the "idea" is the work of the Logic. As the total system falls into three parts, so every part of the system follows the triadic law. Every truth, every reality, has three aspects or stages; it is the unification of two contradictory elements, of two partial aspects of truth which are not merely contrary, like black and white, but contradictory, like same and different. The first step is a preliminary affirmation and unification, the second a negation and differentiation, the third a final synthesis. For example, the seed of the plant is an initial unity of life, which when placed in its proper soil suffers disintegration into its constituents, and yet in virtue of its vital unity keeps these divergent elements together, and reappears as the plant with its members in organic union. Or again, the process of scientific induction is a threefold chain; the original hypothesis (the first unification of the fact) seems to melt away when confronted with opposite facts, and yet no scientific progress is possible unless the stimulus of the original unification is strong enough to clasp the discordant facts and establish a reunification. Thesis, antithesis and synthesis, a Fichtean formula, is generalized by Hegel into the essential law of thought.

In what we may call their psychological aspect these three stages are known as the abstract stage, or that of understanding (*Verstand*), the dialectical stage, or that of negative reason, and the speculative stage, or that of positive reason (*Vernunft*). The first of these attitudes taken alone is dogmatism; the second, when similarly isolated, is scepticism; the third, when detached from its elements, is mysticism. Thus Hegelianism reduces dogmatism, scepticism and mysticism to factors in philosophy. The abstract or dogmatic thinker believes his object to be one, simple and stationary, and intelligible apart from its surroundings. The dialectic of negative reason rudely dispels these views. Appealing to reality it shows that the identity and permanence of forms are contradicted by history; instead of unity it exhibits multiplicity, instead of identity difference, instead of a whole, only parts. Dialectic is, therefore, a dislocating power; it shakes the solid structures of material thought, and exhibits the instability latent in such conceptions of the world. In the realm of abstract thought these transitions take place lightly. In the worlds of nature and mind they are more palpable and violent. But reason is not negative only; while it disintegrates the mass

or unconscious unity, it builds up a new unity with higher organization. What is required is to readjust our original thesis in such a way as to include and give expression to both the elements in the process.

The universe, then, is a process or development, to the eye of philosophy. It is the process of the absolute—in religious language, the manifestation of God. In the background of all, the absolute is eternally present; the rhythmic movement of thought is the self-unfolding of the absolute. God reveals Himself in the logical idea, in nature and in mind; but mind is not alike conscious of its absoluteness in every stage of development. Philosophy alone sees God revealing Himself in the ideal system of thought, as it were "in his eternal being prior to the creation of nature and a finite mind"; in the natural world, as a series of materialized forces and forms of life; and in the spiritual world as the human soul, the legal and moral order of society, and the creations of art, religion and philosophy.

The logic of Hegel is the only rival to the logic of Aristotle. What Aristotle did for the theory of demonstrative reasoning, Hegel attempted to do for the whole of human knowledge. His logic is an enumeration of the forms or categories by which our experience exists. It carried out Kant's doctrine of the categories as *a priori* synthetic principles, but removed the limitation by which Kant denied them any constitutive value except in alliance with experience. According to Hegel the terms in which thought exhibits itself are a system of their own, with laws and relations which reappear in a less obvious shape in the theories of nature and mind. Nor are they restricted to the small number which Kant obtained by manipulating the current subdivision of judgments. But all forms by which thought holds sensations in unity (the formative or synthetic elements of language) had their place assigned in a system where one leads up to and passes over into another.

The fact which ordinary thought ignores, and of which ordinary logic therefore provides no account, is the presence of gradation and continuity in the world. The general terms of language simplify the universe by reducing its variety of individuals to a few forms, none of which exists simply and perfectly. The method of the understanding is to divide and then to give a separate reality to what it has thus distinguished. It is part of Hegel's plan to remedy this one-sided character of thought, by laying bare the gradations of ideas. He lays special stress on the point that abstract ideas when held in their abstraction are almost interchangeable with their opposites—that extremes meet, and that in every true and concrete idea there is a coincidence of opposites.

The beginning of the Logic is an illustration of this. The logical idea is treated under the three heads of being (*Sein*), essence (*Wesen*) and notion (*Begriff*). The simplest term of thought is being; we cannot think less about anything than when we merely say that it is. Being—the abstract "is"—is *nothing* definite, and nothing at least *is*. Being and not being are thus declared identical—a proposition which in this unqualified shape was to most people a stumbling-block at the very door of the system. Instead of the mere "is" which is as yet nothing, we should rather say "becomes," and as "becomes" always implies "something," we have determinate being—"a being" which in the next stage of definiteness becomes "one." And in this way we pass on to the quantitative aspects of being.

The terms treated under the first head, in addition to those already mentioned, are the abstract principles of quantity and number, and their application in measure to determine the limits of being. Under the title of essence are discussed those pairs of correlative terms which are habitually employed in the explanation of the world—such as law and phenomenon, cause and effect, reason and consequence, substance and attribute. Under the head of notion are considered, firstly, the subjective forms of conception, judgment and syllogism; secondly, their realization in objects as mechanically, chemically or teleologically constituted; and thirdly, the idea first of life, and next of science, as the complete interpenetration of thought and objectivity. The third part of logic evidently is what contains the topics usually treated in logic-books, though even here the province of logic in the ordinary

sense is exceeded. The first two divisions—the “objective logic”—are what is usually called metaphysics.

The characteristic of the system is the gradual way in which idea is linked to idea so as to make the division into chapters only an arrangement of convenience. The merit of Hegel is to have indicated and to a large extent displayed the filiation and mutual limitation of our forms of thought; to have arranged them in the order of their comparative capacity to give a satisfactory expression to truth in the totality of its relations; and to have broken down the partition which in Kant separated the formal logic from the transcendental analytic, as well as the general disruption between logic and metaphysics.

Philosophy of Nature.—The Philosophy of Nature starts with the result of the logical development, with the full scientific “idea.” But the relations of pure thought, losing their inwardness, appear as relations of space and time; the abstract development of thought appears as matter and movement. Instead of thought, we have perception; instead of dialectic, gravitation; instead of causation, sequence in time. The whole falls under the three heads of mechanics, physics and “organic”—the content under each varying somewhat in the three editions of the *Encyklopädie*. The charges of superficial analogies, so freely urged against the “Natur-philosophie” by critics who forget the impulse it gave to physical research by the identification of forces then believed to be radically distinct, do not particularly affect Hegel. But in general it may be said that he looked down upon the mere natural world. The meanest of the fancies of the mind and the most casual of its whims he regarded as a better warrant for the being of God than any single object of nature.

His point of view was essentially opposed to the current views of science. To metamorphosis he only allowed a logical value, as explaining the natural classification; the only real, existent metamorphosis he saw in the development of the individual from its embryonic stage. Still more distinctly did he contravene the general tendency of scientific explanation. “It is held the triumph of science to recognize in the general process of the earth the same categories as are exhibited in the processes of isolated bodies. This is, however, an application of categories from a field where the conditions are finite to a sphere in which the circumstances are infinite.” In astronomy he depreciates Newton and elevates Kepler, accusing Newton particularly, à propos of the distinction of centrifugal and centripetal forces, of leading to a confusion between what is mathematically to be distinguished and what is physically separate.

Philosophy of Mind. 1. Psychology.—The third part of the system is the Philosophy of Mind. Its three divisions are the “subjective mind” (psychology), the “objective mind” (philosophic jurisprudence, moral and political philosophy) and the “absolute mind” (the philosophy of art, religion and philosophy). The subjects of the second and third divisions have been treated by Hegel with great detail. The “objective mind” is the topic of the *Rechts-Philosophie*, and of the lectures on the Philosophy of History; while on the “absolute mind” we have the lectures of Aesthetic, on the Philosophy of Religion and on the History of Philosophy—in short, more than one-third of his works.

The purely psychological branch of the subject takes up half of the space allotted to *Geist* in the *Encyklopädie*. It falls under the three heads of anthropology, phenomenology and psychology proper. Anthropology treats of the mind in union with the body—of the natural soul—and discusses the relations of the soul with the planets, the races of mankind, the differences of age, dreams, animal magnetism, insanity and phrenology. In the Phenomenology consciousness, self-consciousness and reason are dealt with. The title of the section and the contents recall, though with some important variations, the earlier half of his first work; but here the historical background on which the stages in the development of the ego were represented has disappeared. Psychology, in the stricter sense, deals with the various forms of theoretical and practical intellect, such as attention, memory, desire and will. In this account of the development of an independent, active and intelligent being from the stage where man like the Dryad is a portion of the natural life around him, Hegel has combined what may be

termed a physiology and pathology of the mind—a subject far wider than that of ordinary psychologies. It is a great merit to have even attempted some system in the dark anomalies which lie under the normal consciousness, and to have traced the genesis of the intellectual faculties from animal sensitivity.

2. Law and History.—The theory of the mind as objectified in the institutions of law, the family and the state is discussed in the “Philosophy of Right.” Beginning with the antithesis of a legal system and morality, Hegel, carrying out the work of Kant, presents the synthesis of these elements in the ethical life (*Sittlichkeit*) of the family and the state. Treating the family as an instinctive realization of the moral life, and not as the result of contract, he shows how by the means of wider associations due to private interests the state issues as the full home of the moral spirit, where intimacy of interdependence is combined with freedom of independent growth. The state is the consummation of man as finite; it is the necessary starting-point whence the spirit rises to an absolute existence in the spheres of art, religion and philosophy. In the finite world or temporal state, religion, as the finite organization of a church, is, like other societies, subordinate to the state. But on another side, as absolute spirit, religion, like art and philosophy, is not subject to the state, but belongs to a higher region.

The political state is always an individual, and the relations of these states with each other and the “world-spirit” of which they are the manifestations constitute the material of history. The *Lectures on the Philosophy of History*, edited by Gans and subsequently by Karl Hegel, is the most popular of Hegel’s works. The history of the world is a scene of judgment where one people and one alone holds for awhile the sceptre, as the unconscious instrument of the universal spirit, till another rises in its place, with a fuller measure of liberty—a larger superiority to the bonds of natural and artificial circumstance. Three main periods—the Oriental, the Classical and the Germanic—in which respectively the single despot, the dominant order, and the man as man possess freedom—constitute the history of the world. Inaccuracy in detail and artifice in the arrangement of isolated peoples are inevitable in such a scheme. A graver mistake, according to some critics, is that Hegel, far from giving a law of progress, seems to suggest that the history of the world is nearing an end, and has merely reduced the past to a logical formula. The answer to this charge is partly that such a law seems unattainable, and partly that the idealistic content of the present which philosophy extracts is always an advance upon actual fact, and so does throw a light into the future. And at any rate the method is greater than Hegel’s employment of it.

3. Art, Religion and Philosophy.—As with Aristotle so with Hegel—beyond the ethical and political sphere rises the world of absolute spirit in art, religion and philosophy. The psychological distinction between the three forms is that sensuous perception (*Anschauung*) is the organon of the first, presentative conception (*Vorstellung*) of the second and free thought of the third. The work of art, the first embodiment of absolute mind, shows a sensuous conformity between the idea and the reality in which it is expressed. The so-called beauty of nature is for Hegel an adventitious beauty. The beauty of art is a beauty born in the spirit of the artist and born again in the spectator; it is not like the beauty of natural things, an incident of their existence, but is “essentially a question, an address to a responding breast, a call to the heart and spirit.” The perfection of art depends on the degree of intimacy in which idea and form appear worked into each other. From the different proportion between the idea and the shape in which it is realized arise three different forms of art. When the idea, itself indefinite, gets no further than a struggle and endeavour for its appropriate expression, we have the symbolic, which is the Oriental, form of art, which seeks to compensate its imperfect expression by colossal and enigmatic structures. In the second or classical form of art the idea of humanity finds an adequate sensuous representation. But this form disappears with the decease of Greek national life, and on its collapse follows the romantic, the third form of art, where the harmony of form and content again grows defective, because the object of Christian art—the

infinite spirit—is a theme too high for art. Corresponding to this division is the classification of the single arts. First comes architecture—in the main, symbolic art; then sculpture, the classical art *par excellence*; they are found, however, in all three forms. Painting and music are the specially romantic arts. Lastly, as a union of painting and music comes poetry, where the sensuous element is more than ever subordinate to the spirit.

The lectures on the Philosophy of Art stray largely into the next sphere and dwell with zest on the close connection of art and religion; and the discussion of the decadence and rise of religions, of the aesthetic qualities of Christian legend, of the age of chivalry, etc., make the *Ästhetik* a book of varied interest.

The lectures on the Philosophy of Religion, though unequal in their composition and belonging to different dates, serve to exhibit the vital connection of the system with Christianity. Religion, like art, is inferior to philosophy as an exponent of the harmony between man and the absolute. In it the absolute exists as the poetry and music of the heart, in the inwardness of feeling. Hegel after expounding the nature of religion passes on to discuss its historical phases, but in the immature state of religious science falls into several mistakes. At the bottom of the scale of nature-worships he places the religion of sorcery. The gradations which follow are apportioned with some uncertainty amongst the religions of the East. With the Persian religion of light and the Egyptian of enigmas we pass to those faiths where Godhead takes the form of a spiritual individuality, *i.e.*, to the Hebrew religion (of sublimity), the Greek (of beauty) and the Roman (of adaptation). Last comes absolute religion, in which the mystery of the reconciliation between God and man is an open doctrine. This is Christianity, in which God is a Trinity, because He is a spirit. The revelation of this truth is the subject of the Christian Scriptures. For the Son of God, in the immediate aspect, is the finite world of nature and man, which far from being at one with its Father is originally in an attitude of estrangement. The history of Christ is the visible reconciliation between man and the eternal. With the death of Christ this union, ceasing to be a mere fact, becomes a vital idea—the Spirit of God which dwells in the Christian community.

The lectures on the History of Philosophy deal disproportionately with the various epochs, and in some parts date from the beginning of Hegel's career. In trying to subject history to the order of logic they sometimes misconceive the filiation of ideas. But they created the history of philosophy as a scientific study. They showed that a philosophical theory is not an accident or whim, but an exponent of its age determined by its antecedents and environments, and handing on its results to the future.

Hegelianism in England.—On the continent of Europe the direct influence of Hegelianism was comparatively short-lived. This was due among other causes to the direction of attention to the rising science of psychology, partly to the reaction against the speculative method. In England and Scotland it had another fate. It supplied a reasoned corrective to prevailing tendencies towards naturalism and ethical individualism, and it offered a speculative vindication of religion, more particularly of the Christian religion. This explains the hold which it obtained upon both English and Scottish thought soon after the middle of the 19th century. The first impulse came from J. F. Ferrier and J. H. Stirling in Scotland, and B. Jowett in Oxford. In the seventies there was a powerful school of English thinkers under the lead of Edward Caird and T. H. Green devoted to the study and exposition of the Hegelian system. With the general acceptance of its main principle that the real is the rational, there came in the eighties a more critical examination of the precise meaning to be attached to it and its bearing on the problems of religion. The earlier Hegelians had interpreted it in the sense that the world in its ultimate essence was not only spiritual but self-conscious intelligence whose nature was reflected inadequately but truly in the finite mind. As time went on it became obvious that without departure from the spirit of idealism Hegel's principle was susceptible of a different interpretation. Granted that rationality taken in the sense of inner coherence and self-consistency is the ultimate standard of truth and reality, does self-consciousness it-

self answer to the demands of this criterion? The question was definitely raised in F. H. Bradley's *Appearance and Reality* (1893; 2nd ed., 1897) and answered in the negative. The completeness and self-consistency which our ideal requires can be realized only in a form of being in which subject and object, will and desire, no longer stand as exclusive opposites, from which it seemed at once to follow that the finite self could not be a reality nor the infinite reality a self. On this basis Bradley developed a theory of the Absolute which, while not denying that it must be conceived of spiritually, insisted that its spirituality is of a kind that finds no analogy in our self-conscious experience. J. M. E. McTaggart's *Studies in Hegelian Dialectic* (1896), *Studies in Hegelian Cosmology* (1901) and *Some Dogmas of Religion* (1906) and *Commentary on Hegel's Logic* (1910) opened a new chapter in the critical interpretation of Hegelianism. More valuable and reliable as an exposition of Hegel thought are the writings of W. Wallace, especially his *Prolegomena to Hegel's Logic* (2nd ed., 1892). The writer who has perhaps done more than any other to commend with persuasive logic to English readers the essential spirit of Hegelianism is Bernard Bosanquet. While carrying forward the thought of Bradley on independent lines, and owing much to Greek idealisms, he was profoundly influenced by Hegel. His works *The Principle of Individuality and Value* (1911), and *The Value of Destiny of the Individual* (1912) may be said to be the finest and the final efflorescence of English idealism of the second half of the 19th century.

Among Italian Hegelians are A. Vera, Raffaele Mariano and B. Spaventa (1817–1883); see V. de Lucia, *L'Hegel in Italia* (1891). In Sweden, J. J. Borelius of Lund; in Norway, G. V. Lyng (d. 1884), M. J. Monrad (1816–1897) and G. Kent (d. 1892) have adopted Hegelianism; in France, P. Leroux and P. Prévost.

Works and Life.—Hegel's collected *Werke* appeared in 18 vols. (1832–40); vols. i.–viii. containing works previously published. New edition by G. Lasson (pub. Meiner, Leipzig); begun 1907; 10 vols. published in 1928. English translations are: J. Sibree, *Philosophy of History* (1857); B. Bosanquet, *Philosophy of Fine Art; Introduction* (1886); W. Hastie, *Philosophy of Art* (1886); W. Wallace, *Logic of Hegel* (1892); and *Philosophy of Mind* (1894); E. S. Haldane and F. H. Simson, *History of Philosophy* (1892); E. B. Spiers and J. B. Sanderson, *Philosophy of Religion* (1895); W. Dyde, *Philosophy of Right* (1896); J. B. Baillie, *Phenomenology of Mind* (1910).

HEGEMON OF THASOS, Greek writer of the old comedy, flourished during the Peloponnesian War. According to Aristotle (*Poetics*, ii. 5) he was the inventor of a kind of parody; by slightly altering the wording in well-known poems he transformed the sublime into the ridiculous.

Fragments in T. Kock, *Comicorum Atticorum fragmenta*, i. (1880); B. J. Peltzer, *De parodica Graecorum poesi* (1855).

HEGEMONY, the leadership especially of one particular state in a group of federated or loosely united states. The term was first applied in Greek history to the position claimed by different individual city-states, e.g., by Athens and Sparta, at different times to a position of predominance among other equal states, coupled with individual autonomy. The reversion of this position was claimed by Macedon (see GREECE: *Ancient History*, and DELIAN LEAGUE).

HEGESIAS OF MAGNESIA (in Lydia), Greek rhetorician and historian, flourished about 300 B.C. Strabo (xiv. 648) speaks of him as the founder of the florid "Asiatic" style (see TIMAEUS). Agatharchides, Dionysius of Halicarnassus and Cicero all speak of him in disparaging terms, although Varro seems to have approved of his work. He professed to imitate the simple style of Lysias, avoiding long periods and expressing himself in short, jerky sentences, but his vulgar affectation and bombast made his writings a mere caricature of the old Attic.

See C. W. Müller, *Scriptores rerum Alexandri Magni*, p. 138 (appendix to Didot ed. of Arrian, 1846); Norden, *Die antike Kunstprosa* (1898); J. B. Bury, *Ancient Greek Historians* (1909), pp. 169-172, on origin and development of "Asiatic" style, with example from Hegesias. Fragments and references in ancient authorities in F. Jacoby, *Fragmente der griechischen Historiker* (1927), vol. ii.

HEGESIPPUS, Athenian orator and statesman, nicknamed Κρόβυλος ("knot"), probably from the way in which he wore his hair. He lived in the time of Demosthenes, whose anti-Macedonian policy he supported. In 343 B.C. he was one of the ambassadors sent to Philip to discuss the restoration of the island of Halonnesus. Soon afterwards Philip wrote to Athens, offering to resign the island or to submit to arbitration the question of ownership. In reply to this letter the oration *De Halonneso* was delivered, which, although included among the speeches of Demosthenes, is generally considered to be by Hegesippus. Dionysius of Halicarnassus and Plutarch, however, favour the authorship of Demosthenes.

See Demosthenes, *De falsa legatione* 364, 447, *De corona* 250, *Philippica* iii. 129; Plutarch, *Demosthenes* 17, *Apophthegmata*, 187D; Dionysius Halic., *ad. Ammaeum*, i.; see also Grote, *History of Greece*, ch. 90.

HEGESIPPUS (fl. A.D. 150-180), early Christian writer, was of Palestinian origin, and lived under the Emperors Antoninus Pius, Marcus Aurelius and Commodus. He belonged to that group of Judaistic Christians which, while keeping the law themselves, did not attempt to impose on others the requirements of circumcision and Sabbath observance. He was the author of a treatise (*ὑπομνήματα*) in five books dealing with various aspects of the Christian Religion, fragments of which are found in Eusebius. Hegesippus was also a great traveller, and like many other leaders of his time came to Rome about the middle of the 2nd century. His journeyings impressed him with the idea that the continuity of the church in the cities he visited was a guarantee of its fidelity to apostolic orthodoxy: "in each succession and in every city, the doctrine is in accordance with that which the Law and the Prophets and the Lord (i.e., the Old Testament and the evangelical tradition) proclaim." To illustrate this opinion he drew up a list of the Roman bishops.

HEGESIPPUS, the supposed author of a free Latin adaptation of the *Jewish War* of Josephus under the title *De bello Judaico et excidio urbis Hierosolymitanæ*. The seven books of Josephus are compressed into five, but much has been added from

the *Antiquities* and from the works of Roman historians, while several entirely new speeches are introduced to suit the occasion. Internal evidence shows that the work could not have been written before the 4th century A.D. The author, who is undoubtedly a Christian, describes it in his preface as a kind of revised edition of Josephus. Some authorities attribute it to Ambrose, bishop of Milan (340-397), but there is nothing to settle the authorship definitely. The name Hegesippus itself appears to be a corruption of Josephus, through the stages Ἰώσηπος, Iosippus, Egesippus, Hegesippus, unless it was purposely adopted as reminiscent of Hegesippus, the father of ecclesiastical history (2nd century).

Best edition by C. F. Weber and J. Caesar (1864); authorities in E. Schürer, *History of the Jewish People* (Eng. trans.), i. 99 seq.; F. Vogel, *De Hegesippo, qui dicitur, Josephi interprete* (Erlangen, 1881).

HEGIUS (VON HEEK), ALEXANDER (c. 1433-1498), German humanist, so called from his birthplace Heek in Westphalia. In his youth he was a pupil of Thomas à Kempis, at that time canon of the convent of St. Agnes at Zwolle. In 1474 he settled down at Deventer in Holland, where he either founded or succeeded to the headship of a school, which had many famous pupils, chief of whom was Erasmus. Hegius died at Deventer on Dec. 7, 1498. His writings were published after his death by his pupil Jacob Faber, but his fame rests not on these, but upon his services in the cause of humanism. He succeeded in abolishing the old-fashioned mediaeval textbooks and methods of instruction, and led his pupils to the study of the classical authors themselves.

See D. Reichling, "Beiträge zur Charakteristik des Alex. Hegius," in the *Monatsschrift für Westdeutschland* (1877); H. Hamelmann, *Opera genealogico-historica* (1711); H. A. Erhard, *Geschichte des Wiederaufblühens wissenschaftlicher Bildung* (1826); C. Kraft and W. Creelius, "Alexander Hegius und seine Schüler," from the works of Johannes Butzbach, one of Hegius's pupils, in *Zeitschrift des bergischen Geschichtsvereins*, vii. (Bonn, 1871).

HEHE, a Bantu tribe inhabiting the Tanganyika plateau, combining agriculture with animal husbandry. Sheep, goats and fowls are kept in addition to cattle, the care of which is almost exclusively man's province, while women are responsible for agricultural economics, raising millet, yams, maize and a variety of leguminous and other vegetable crops. While their characteristics are chiefly Eastern they display certain lacustrine contacts and Southern influences can be traced in their internal organization.

The most characteristic feature is the *tembe*, a long building partitioned into separate chambers for families. Each chamber is subdivided into two rooms, the outer one for boys, the inner for women and the head of the family. A *tembe* varies in size from one sufficient for a few families to the length of a kilometre, and a village may consist of anything from one small *tembe* to a number of large ones adjoining. The houses are made of palings neatly plastered with clay, with a slightly curved roof also constructed with palings covered with rushes and caulked with clay.

Kinship is mainly reckoned in the paternal line and the maternal kinship imposes obligations for one generation only, whereas any paternal relationship that can be proved in the remotest degree is important and is a bar to marriage. Marriage is arranged between a man and the bride's father and involves the payment of a dowry by the former. Polygyny is practised, but the first wife must be the mother's brother's daughter, and only after this statutory marriage may a man exercise his own choice. On marriage a boy or girl leaves the family chamber and builds anew. A peculiar system of totemism prevails, as every one possesses one or two totems inherited paternally. The totem may be an animal or part of an animal or a part of all animals, for instance a sheep's head or the heart of all animals. But though there is no prohibition against killing the totem, a dispensatory ceremony is required before it may be eaten. The possession of the same totem is no bar to marriage unless a common paternal ancestor can also be determined.

The weapons employed are the heavy-bladed thrusting spear, light throwing spears with barbed blades and a battle axe, showing an influence which is probably traceable to the Angoni. A large oval shield of ox-hide is carried.

The Hehe believe in a vague deity *Nguruhe*, who controls things

in general but to whom neither prayers nor sacrifices are offered. Their religion consists mainly of the worship of ancestor-spirits (*masoka*), to whom prayers are made for success and prosperity and the avoidance of evils. Offerings of grain, milk or flesh are made at the grave of an ancestor by the head of the family.

See E. Nigmann, *Die Waheke* (1908).

(J. H. D.)

HEIBERG, JOHAN LUDVIG (1791–1860), Danish poet and critic, son of the political writer Peter Andreas Heiberg (1758–1841), and of the novelist, afterwards the Baroness Gyllembourg-Ehrensvärd (*q.v.*), was born at Copenhagen on Dec. 14, 1791. In 1800 his father was exiled and settled in Paris, where he was employed in the French foreign office, retiring in 1817 with a pension. His political and satirical writings continued to exercise great influence over his fellow-countrymen. Johan Ludvig Heiberg was taken by K. L. Rahbek and his wife into their house at Bakkehuset. He was educated at the University of Copenhagen, and his first publication, entitled *The Theatre for Marionettes* (1814), included two romantic dramas. This was followed by *Christmas Jokes and New Year's Tricks* (1816), *The Initiation of Psyche* (1817), and *The Prophecy of Tycho Brahe*, a satire on the eccentricities of the Romantic writers, especially on the sentimentality of Ingemann. In 1817 Heiberg took his degree, and in 1819 went abroad with a grant from Government. He spent the next three years abroad with his father. In 1822 he published his drama of *Nina*, and was made professor of the Danish language at the University of Kiel, where he delivered a course of lectures, comparing the Scandinavian mythology as found in the *Edda* with the poems of Öhlenschläger. These lectures were published in German in 1827.

In 1825 Heiberg came back to Copenhagen with the intention of introducing the vaudeville on the Danish stage. He composed a great number of these vaudevilles; he took his models from the French theatre but the subjects and the humour were essentially Danish and even topical. Meanwhile he was producing dramatic work of a more serious kind; in 1828 he brought out the national drama of *Elverhöi*; in 1830 *The Inseparables*; in 1835 the fairy comedy of *The Elves*, a dramatic version of *Tieck's Elfin*; and in 1838 *Fata Morgana*. In 1841 Heiberg published a volume of *New Poems* containing "A Soul after Death," a comedy which is perhaps his masterpiece, "The Newly Wedded Pair," and other pieces. He edited from 1827 to 1830 the famous weekly, the *Flyvende Post*, and subsequently the *Interimsblade* (1834–37) and the *Intelligensblade* (1842–43). In his journalism he combated the excessive pretensions of the Romantics, and produced much valuable and penetrating criticism of art and literature. In 1831 he married the actress Johanne Louise Paetges (1812–90), herself the author of some popular vaudevilles.

Heiberg's scathing satires made him very unpopular; and this antagonism reached its height when, in 1845, he published his malicious little drama of *The Nut Crackers*. Nevertheless he became in 1847 director of the national theatre. He filled the post for seven years, working with great zeal and conscientiousness, but was forced by intrigues from without to resign it in 1854. Heiberg died at Bonderup Aug. 25, 1860.

The poetical works of Heiberg were collected, in 11 vols., in 1861–62, and his prose writings (11 vols.) in the same year. The last volume of his prose works contains some fragments of autobiography. For the elder Heiberg see monographs by Thaarup (1883) and by Schwanenflügel (1891). For the younger Heiberg see P. Hansen, *Om J. L. Heiberg* (1867), and J. Clausen, *Kulturhistoriske studier over Heibergs Vaudeviller* (1891).

HEIDE, a town in the Prussian province of Schleswig-Holstein, on a small plateau between the marshes and moors bordering the North Sea, 35 m. N.N.W. of Glückstadt. Pop. (1925) 10,656. In 1447 it became the capital of the Dithmarsh peasant republic, but on June 13, 1559 it was the scene of the complete defeat of the peasant forces by the Danes.

HEIDEGGER, JOHANN HEINRICH (1633–1698), Swiss theologian, was born at Bärentschweil, in the canton of Zürich, Switzerland, on July 1, 1633. After studying in Germany he settled in 1665 in Zürich, where he was successively professor of moral philosophy and of theology. He died there on Jan. 18, 1698. Heidegger was the principal author of the *Formula Con-*

sensus Helvetica in 1675, which was designed to unite the Swiss Reformed churches, but had an opposite effect.

His writings include: *De historia sacra patriarcharum exercitationes selectae* (1667–71); *De ratione studiorum, opuscula aurea*, etc. (1670); *Historia papatus* (1684; under the name Nicander von Hohenegg); *Manuductio in viam concordiae Protestantium ecclesiasticae* (1686); *Tumulus concilii Tridentini* (1690); *Exercitationes biblicae* (1700), with a life of the author prefixed; *Corpus theologiae Christianae* (1700, edited by J. H. Schweizer); *Ethicae Christianae elementa* (1711); and lives of his friends J. H. Hottinger (1667) and J. L. Fabricius (1698). His autobiography appeared in 1698, under the title *Historia vitae J. H. Heideggeri*.

See the articles in Herzog-Hauck's *Realencyklopädie* and the *Allgemeine deutsche Biographie*; and cf. W. Gass, *Geschichte der protestantischen Dogmatik*, ii. 353 ff.

HEIDELBERG, the name of two towns in South Africa: (a) 26° 31' S., 28° 22' E. Altitude, 5,026 feet. Pop. (1921), 2,084 white and about 1,500 natives. The town is built on the Blesbok spruit, just on the south-eastern side of the Witwatersrand gold-fields. It is situated in the Transvaal, 42 m. S.E. of Johannesburg, and 450 m. from Durban. The town possesses five schools and a training college. The District of Heidelberg extends southward to the Vaal river, and is part of the great maize triangle of South Africa. (b) 34° 5' S., 20° 59' E., situated on the Duivenhoeke river in the Cape Province, 100 ft. above sea-level. It is a small town with a white population of 994 (1926), and about an equal number of coloured people. The principal productions of the district are wool and aloes.

HEIDELBERG, a town of Germany, on the south bank of the Neckar, 12 m. above its confluence with the Rhine, 13 m. S.E. from Mannheim and 54 m. from Frankfurt-on-Main by rail. The town lies between lofty hills covered with vineyards and forests, at the spot where the rapid Neckar leaves the gorge and enters the plain of the Rhine. The town itself consists practically of one long, narrow street—the Hauptstrasse—running parallel to the river. A number of smaller streets intersect the Hauptstrasse at right angles and run down to the river. Heidelberg is an important railway centre, and is connected by trunk lines with Frankfurt, Mannheim, Karlsruhe, Spire and Würzburg. Of the churches the chief are the Protestant Peterskirche dating from the 15th century and restored in 1873, to the door of which Jerome of Prague in 1460 nailed his theses; the Heilige Geist Kirche (Church of the Holy Ghost), an imposing Gothic edifice of the 15th century; and the Jesuitenkirche (Roman Catholic), with a decorated interior.

Heidelberg castle, overhanging the east of the town, stands on the Jettenbühl, a spur of the Königsstuhl (1,800 ft.), 330 ft. above the Neckar. It is one of the chief monuments of Germany, begun in the 13th century and extended by addition of a wing, Ruprechtsbau, under the elector palatine and the German king Rupert III. (d. 1410). Otto Henry "the Magnanimous" (d. 1559), built the beautiful early Renaissance wing (1556–59); the fine late Renaissance wing called the Friedrichsbau was added (1601–07) under Frederick IV.; and, on the west side, the Elisabethenbau or Englischebau (1618), named after his wife, the daughter of James I. of Great Britain, built under Frederick V. At the peace of Westphalia, Heidelberg was given back to Frederick V.'s son, Charles Louis, who restored the castle. At the end of the 17th century it was despoiled by the French and finally, in 1764, it was struck by lightning and reduced to ruin. Apart from outworks, the castle is an irregular square with round towers at the angles, the principal buildings being grouped round a central courtyard containing the Alte Bau and the Bandhaus with the entrance from the south through a series of gateways. In this courtyard, besides the buildings already mentioned, are the oldest parts of the castle, the so-called Alte Bau (old building) and the Bandhaus. The Friedrichsbau was elaborately restored and rendered habitable between 1897 and 1903. The fountain in the courtyard is decorated with four granite columns from Charlemagne's palace at Ingelheim; the Elisabethentor is a beautiful gateway named after the English princess, there is a beautiful octagonal bell-tower at the north-east angle; and the castle chapel and the museum of antiquities are in the Friedrichsbau. In a cellar entered from the courtyard is the famous vat built in 1751, which has been used only occasionally. Its capacity is 49,000 gal., and it is 20 ft.

high and 31 ft. long. Behind the Friedrichsbau is the Altan (1610), or castle balcony with a magnificent view.

The university of Heidelberg was founded by the elector Rupert I., the bull of foundation being issued by Pope Urban VI. in 1385. It was constructed after the type of Paris, and had four faculties; Otto Henry gave it a new organization, further endowed it and founded the library, first kept in the choir of the Heilige Geist Kirche, and consisting of 3500 mss. In 1623 it was sent to Rome by Maximilian I. of Bavaria, and stored as the Bibliotheca Palatina in the Vatican. It was afterwards taken to Paris, and in 1815 was restored to Heidelberg. At the Reformation it became a stronghold of Protestant learning. Damaged by the Thirty Years' War, it led a struggling existence for a century and a half and many of its endowments were cut off by the peace of Lunéville (1801). In 1803, however, Charles Frederick, grand-duke of Baden, raised it anew and reconstituted it.

Heidelberg makes metalware, pianos, cigars, leather, cement, surgical instruments and beer, but is largely concerned with catering for tourists and students. Pop. (1925) 73,034.

HEIDELBERG CATECHISM, THE, the most attractive of all the catechisms of the Reformation, was drawn up at the bidding of Frederick III., elector of the Palatinate, and published on Tuesday the 19th of January 1563. The task was entrusted to two young men who have won deserved remembrance alike by their learning and their character: Zacharias Ursinus (1536–1583), a man of modest and gentle spirit, unwearied in study and well fitted to impart his learning to others; and Caspar Olevianus (1536–1587), whose ardour and enthusiasm made him the happy complement of Ursinus. The elector could have chosen no better men, young as they were, for the task in hand. As a first step each drew up a catechism of his own composition, that of Ursinus being naturally of a more grave and academic turn than the freer production of Olevianus, while each made full use of the earlier catechisms already in use. But when the union was effected it was found that the spirits of the two authors were most happily and harmoniously wedded, the exactness and erudition of the one being blended with the fervency and grace of the other. Thus the Heidelberg Catechism, which was completed within a year of its inception, has an individuality that marks it out from all its predecessors and successors. The Heidelberg synod unanimously approved of it; it was published in January 1563, and in the same year officially turned into Latin. The Heidelberg book, in spite of violent attacks on it by the extreme Lutherans, rapidly passed beyond the bounds of the Palatinate and gained an abundant success not only in Germany but also in the Netherlands and in the Reformed churches of Hungary, Transylvania and Poland. It was officially recognized by the synod of Dort in 1619, passed into France, Britain and America, and probably shares with the *De imitatione Christi* and *The Pilgrim's Progress* the honour of coming next to the Bible in the number of tongues into which it has been translated.

This wide acceptance and high esteem are due largely to an avoidance of polemical and controversial subjects, and even more to an absence of the controversial spirit. There is no mistake about its Protestantism, even when we omit the unhappy addition made to answer 80 by Frederick himself (in indignant reply to the ban pronounced by the Council of Trent), in which the Mass is described as "nothing else than a denial of the one sacrifice and passion of Jesus Christ, and an accursed idolatry"—an addition which is the one blot on the *ἐπιτομή* of the catechism. The work is the product of the best qualities of head and heart, and its prose is frequently marked by all the beauty of a lyric. It follows the plan of the epistle to the Romans (excepting chapters ix.–xi.) and falls into three parts: Sin, Redemption and the New Life. This arrangement alone would mark it out from the normal Reformation catechism, which runs along the stereotyped lines of Decalogue, Creed, Lord's Prayer, Church and Sacraments. These themes are included, but are shown as organically related.

Smellie (London, 1900), and *The Heidelberg Catechism* (New York, 1863), with introduction and German, Latin and English text; also Schaff, *Creeds of Christendom*, vols. i. 529 ff. and iii. 307 ff., and Müller,

Die Bekenntnisschriften der Reformierten Kirche (Leipzig, 1903).

HEIDENHEIM, a town of Germany, in the republic of Württemberg, 31 m. by rail N. by E. of Ulm. Pop. (1925) 19,363. The town, which received municipal privileges in 1356, is overlooked by the ruins of the castle of Hellenstein, standing on a hill 1,985 ft. high. Its industrial establishments include cotton, tobacco, machinery, metal and rubber factories, bleach-works, dye-works and breweries. Heidenheim is also the name of a small place in Bavaria famous on account of the Benedictine abbey, founded in 748 by the bishop of Eichstätt, which formerly stood therein. It was plundered by the peasantry in 1525 and was closed in 1537.

HEIDENSTAM, VERNER VON (1859–), Swedish writer, was born on July 6, 1859, in Olshammar. He lived for several years in the south of Europe, Egypt and the East. On his return home, he published a collection of poems, *Vallfart och Vandringsaar* (Pilgrimage and Years of Wandering) (1888), based on oriental life, which formed a protest against the naturalism then prevalent in Swedish literature. This book marked the beginning of the great literary renaissance of the '90s in Sweden. In 1889 he published *Endymion*, an oriental story, and in 1892 his great work, *Hans Alienus*, a fanciful epic concerning a pilgrimage in search of beauty through various ages and countries. His other collection of *Poems* (1895) indicates the author's transition to national ideas. This national tendency attained its zenith in his great prose work, *Karolinerna* (2 vols., 1897–98; Eng. trans. *The Carlists*, 1902), dealing with the time of Charles XII. Then followed *Den Hellige Birgittas Pilegrimsfärd* (St. Bridget's Pilgrimage) in 1901; descriptions of Sweden in ancient times and in the Middle Ages in *Folkungaträdet* (2 vol., 1905, 1920), and *Svenskarna og deres hövdingar* (Swedes and Their Chieftains, 2 vol., 1908, 1909). In 1915 Heidenstam published *Nya Dikter*, which established him as the greatest of contemporary Swedish lyricists, and in 1916 he was awarded the Nobel prize for literature.

See F. Böök, *Sveriges moderna litteratur* (2nd ed., 1921).

HEIFER, a young cow that has not calved.

HEIJERMANS, HERMANN (1864–1924), Dutch writer, of Jewish origin, was born on Dec. 3, 1864, at Rotterdam. In the Amsterdam *Handelsblad* he published a series of realistic sketches of Jewish family life under the pseudonym of "Samuel Falkland," which were collected in volume form. His novels and tales include *Trinette* (1892), *Fles* (1893), *Kamertjeszonde* (2 vols., 1896), *Intérieurs* (1897), *Diamantstadt* (2 vols., 1903). He created great interest by his play *Op Hoop van Zegen* (1900), represented at the Théâtre Antoine in Paris, and in English by the Stage Society as *The Good Hope*. His other plays include: *Dora Kremer* (1893), *Ghetto* (1898), *Ora et labora* (1901), *De Groote Vlucht* (1908), *Eva Bonheur* (1919). A *Case of Arson*, an English version of the one-act play *Brand in de Jonge Jan*, was notable for the impersonation (1904 and 1905) by Henri de Vries of all the seven witnesses who appear as characters. Heijermans lived for a few years in Berlin, but returned to Holland in 1912 in order to manage a society of players. He died at Zantvoort on Nov. 22, 1924.

HEILBRONN, a town of Germany, in the republic of Württemberg, on the Neckar, 33 m. by rail N. of Stuttgart, and at the junction of lines to Crailsheim and Eppingen. Pop. (1925) 45,520. Heilbronn occupies the site of an old Roman settlement; it is first mentioned in 741, and the Carolingian princes had a palace here. It owes its name—originally Heiligbronn, or holy spring—to a spring of water which used to be seen issuing from under the high altar of the church of St. Kilian.

The older streets are narrow, and contain a number of high turreted houses with quaint gables. The principal public buildings are the church of St. Kilian (restored 1886–1895) in the Gothic and Renaissance styles, begun about 1019 and completed in 1529, with a tower 210 ft. high, a beautiful choir, and a finely carved altar; the town hall (Rathaus), founded in 1540, and possessing a curious clock made in 1580; the house of the Teutonic knights (Deutsches Haus); the Roman Catholic church of St. Joseph, formerly the church of the Teutonic Order; and the tower (Diebsturm or Götzens Turm) on the Neckar. The town is commer-

cially the most important in Württemberg, and possesses an immense variety of manufactures, of which the principal are gold, silver, steel and iron wares, machines, motor cars, sugar of lead, white lead, vinegar, beer, sugar, tobacco, soap, oil, chemicals, artificial manure, glue, soda, paper and leather.

HEILSBERG, a town in the province of East Prussia, at the junction of the Simser and Alle, 38 m. S. of Königsberg. Pop. (1925) 7,033. It has an old castle, founded by the Teutonic order in 1240, which was from 1306–c. 1800 the seat of the bishops of Ermeland. In 1807 the French fought the Russians and Prussians nearby. The principal industries are tanning, dyeing and brewing, and there is considerable trade in grain.

HEILSBRONN or **KLOSTER-HEILSBRONN**, a village of Germany, in the Bavarian province of Middle Franconia, on the railway between Nürnberg and Ansbach, has 1,500 inhabitants. In the middle ages it possessed one of the great monasteries of Germany, which belonged to the Cistercian order and owed its origin to Bishop Otto of Bamberg in 1132, existing till 1555. Its sepulchral monuments are of exceptionally high artistic interest. It was the hereditary burial-place of the Hohenzollern family. The buildings of the monastery have mostly disappeared, with the exception of the fine church, a Romanesque basilica, restored between 1851 and 1866, and possessing paintings by Albert Dürer.

HEIM, ALBERT VON ST. GALLEN (1849–), Swiss geologist, was born at Zürich on April 12, 1849. He was educated at Zürich and Berlin universities, and became professor of geology at Zürich, and director of the geological survey of Switzerland. With E. Schmidt he prepared the geological map of Switzerland (2nd ed. 1912). His researches on the structure of the Alps threw light on the structure of mountain masses in general. He traced the plications from minor to major stages, and illustrated the remarkable foldings and overthrust faultings in numerous sections with the aid of pictorial drawings. His *Mechanismus der Gebirgsbildung* (1878) is a classic.

HEIMDAL or **HEIMDALL**, in Scandinavian mythology, keeper of the gates of Heaven, guardian of the rainbow bridge Bifrost, used by the gods between heaven and earth, son of Odin by nine virgins. He lives in the fort of Himinsbiorg at the end of Bifrost. Nothing can escape his vigilance, for he sleeps less than a bird, sees at night and in his sleep, can hear grass and the wool on a lamb's back grow. With Gjallar (*q.v.*) he will summon the gods on the day of judgment.

HEINE, HEINRICH (1797–1856), German poet and journalist, was born at Düsseldorf, of Jewish parents, on the 13th of December 1797. He was the eldest of four children, and received his education, first in private schools, then in the Lyceum of his native town. When he left school in 1815, an attempt was made to engage him in business in Frankfort, but without success. In the following year his uncle, Solomon Heine, a wealthy banker in Hamburg, took him into his office. A passion for his cousin Amalie Heine seems to have made the young man more contented with his lot in Hamburg, and his success was such that his uncle decided to set him up in business for himself. But in a very few months the firm of "Harry Heine & Co." was insolvent. His uncle now generously provided him with money to enable him to study at a university, with the view to entering the legal profession, and in the spring of 1819 Heine became a student at Bonn. During his stay there he devoted himself rather to the study of literature and history than to that of law. In the autumn of 1820 Heine left Bonn for Göttingen, where he proposed to devote himself more assiduously to professional studies, but in February of the following year he challenged to a pistol duel a fellow-student who had insulted him, and was, in consequence, rusticated for six months. The pedantic atmosphere of the university of Göttingen was, however, little to his taste; the news of his cousin's marriage unsettled him still more; and he was glad of the opportunity to seek distraction in Berlin.

In the Prussian capital a new world opened up to him; a very different life from that of Göttingen was stirring in the new university there. He was also fortunate in having access to the chief literary circles of the capital; he was on terms of intimacy with Varnhagen von Ense and his wife, the celebrated Rahel, and

made the acquaintance of leading men of letters like Fouqué and Chamisso. Under such favourable circumstances his own gifts were soon displayed. He contributed poems to the *Berliner Gesellschafter*, some of which were subsequently incorporated in the *Buch der Lieder*, and in December 1821 a little volume came from the press entitled *Gedichte*. He was also employed at this time as correspondent of a Rhenish newspaper, as well as in completing his tragedies *Almansor* and *William Ratcliff*, which were published in 1823. Heine had plans of settling in Paris, but as he was still dependent on his uncle, the latter's consent had to be obtained. As was to be expected, Solomon Heine did not favour the new plan, but promised to continue his support on the condition that Harry completed his course of legal study. He sent the young student for a six weeks' holiday at Cuxhaven, which opened the poet's eyes to the wonders of the sea; and three weeks spent subsequently at his uncle's county seat near Hamburg were sufficient to awaken a new passion—this time for Amalie's sister, Therese. In January 1824 Heine returned to Göttingen, where, with the exception of a visit to Berlin and the excursion to the Hartz mountains in the autumn of 1824, which is immortalized in the first volume of the *Reisebilder*, he remained until his graduation in the summer of the following year. A few weeks before obtaining his degree, he took a step which he had long meditated: he formally embraced Christianity. This "act of apostasy," was actuated by practical considerations. The summer months which followed his examination Heine spent by his beloved sea in the island of Norderney. The question of his future now became pressing, and for a time he seriously considered the plan of settling as a solicitor in Hamburg, and hoped to marry his cousin Therese. Meanwhile he had made arrangements for the publication of *Die Harzreise*, which appeared in May 1826. The success of the book was instantaneous. Its lyric outbursts and flashes of wit; its rapid changes from grave to gay; its flexibility of thought and style, came as a revelation to its generation. It was followed in 1827 by the most famous of all Heine's works, the *Buch der Lieder*.

In the spring of the following year Heine paid a long planned visit to England, where he was impressed by the free and vigorous public life, by the size and bustle of London; above all, he was filled with admiration for Canning. But the picture had also its reverse; the sordidly commercial spirit of English life and brutal egotism of the ordinary Englishman, grated on Heine's sensitive nature; he missed the finer literary and artistic tastes of the continent and was repelled by the austerity of English religious sentiment and observance. Unfortunately the latter aspects of English life left a deeper mark on his memory than the bright side. In October Cotta, the well-known publisher, offered Heine—the second volume of whose *Reisebilder* and the *Buch der Lieder* had meanwhile appeared—the joint-editorship of the *Neue allgemeine politische Annalen*. He gladly accepted the offer and betook himself to Munich. Heine did his best to adapt himself to the new surroundings. But the stings of the *Reisebilder* were not so easily forgotten; the clerical party in particular did not leave him long in peace. In July 1828, he left Munich for Italy, where he remained until the following November, a holiday which provided material for the third and part of the fourth volumes of the *Reisebilder*. In the beginning of 1829 Heine took up his abode in Berlin, where he resumed old acquaintanceships; in summer he was again at the sea, and in autumn he returned to Hamburg, where he virtually remained until May 1831. These years were not a happy period of the poet's life; his efforts to obtain a position, apart from that which he owed to his literary work, met with rebuffs on every side; his relations with his uncle were unsatisfactory, and for a time he was seriously ill. When in 1830 the news of the July Revolution in the streets of Paris reached him, Heine hailed it as the beginning of a new era of freedom, and his thoughts reverted once more to his early plan of settling in Paris. All through the following winter the plan ripened, and in May 1831 he finally said farewell to his native land.

Heine's first impressions of Paris were jubilantly favourable. He was soon on friendly terms with many of the notabilities of the capital; and there was every prospect of a congenial and

lucrative journalistic activity as correspondent for German newspapers. Two series of his articles were subsequently collected and published under the titles *Französische Zustände* (1832) and *Lutezia* (written 1840–1843, published in the *Vermischte Schriften*, 1854). In December 1835, however, the German Bund, incited by W. Menzel's attacks on "Young Germany," issued its notorious decree, forbidding the publication of any writings by the members of that coterie; the name of Heine headed the list. This was the beginning of a series of literary feuds in which Heine was, from now on, involved; and they curtailed considerably his sources of income. His uncle, it is true, had allowed him 4,000 francs a year when he settled in Paris, but at this moment he was not on the best of terms with his Hamburg relatives. In these circumstances he was induced to apply to the French government for support from a fund formed for the benefit of "political refugees" who were willing to place themselves at the service of France. From 1836 or 1837 until the Revolution of 1848 Heine was in receipt of 4,800 francs annually from this source.

In October 1834 Heine made the acquaintance of a young Frenchwoman, Eugénie Mirat, a saleswoman in a boot-shop in Paris. Although ill-educated, vain and extravagant, she inspired the poet with a deep and lasting affection, and in 1841, on the eve of a duel in which he was involved, he made her his wife. Her death occurred in 1883. His relations with her helped to weaken his ties with Germany; he only revisited it twice, in the autumn of 1843 and the summer of 1847. In 1845 appeared the first unmistakable signs of the terrible spinal disease, which, for eight years, from the spring of 1848 till his death, condemned him to a "mattress grave." These years of suffering—suffering which left his intellect as clear and vivacious as ever—seem to have effected a spiritual purification in Heine's nature, and to have brought out the better sides of his character. The lyrics of the *Romanzero* (1851) and the collection of *Neueste Gedichte* (1853–54) surpass in sincerity at least the poetry of the *Buch der Lieder*. Most wonderful of all are the poems inspired by Heine's strange mystic passion for the lady he called *Die Mouche*, a countrywoman of his own—her real name was Elise von Krientz, but she had written in French under the *nom de plume* of Camille Selden—who helped to brighten the last months of the poet's life. He died on Feb. 17, 1856, and lies buried in Montmartre.

Between 1833 and 1839 Heine published a collection of prose writings under the title *Der Salon* (1834–1840). It includes, besides papers on French art and the French stage, *Zur Geschichte der Religion und Philosophie in Deutschland*, *Aus den Memoiren des Herrn von Schnabelewopski*, *Der Rabbi von Bacherach* and *Florentinische Nächte*. *Die romantische Schule* (1836) is disfigured by an unpardonable personal attack on the elder Schlegel. In 1839 appeared *Shakespeares Mädchen und Frauen*, the text to a series of illustrations; and in 1840, the witty and trenchant satire on a writer, who, in spite of many personal disagreements, had been Heine's fellow-fighter in the liberal cause, Ludwig Börne. Of Heine's poetical work in these years, his most important publications were, besides the *Romanzero*, the two satirical poems, *Deutschland, ein Wintermärchen* (1844), the result of his visit to Germany, and *Atta Troll, ein Sommernachtstraum* (1847), an attack on the politically inspired literature of the 'forties.

In the case of no other of the greater German poets is it so hard to arrive at a final judgment as in that of Heinrich Heine. In his *Buch der Lieder* he unquestionably struck a new lyric note, not merely for Germany but for Europe. No singer before him had been so daring in the use of nature-symbolism as he, none had given such concrete expression to the spiritual forces of heart and soul. At times, it is true, his imagery is exaggerated to the degree of absurdity, but it exercised, none the less, a fascination over his generation. His lyric appealed with particular force to foreign peoples, who had less understanding for the intangible, undefinable spirituality which the German people regard as an indispensable element in their national lyric poetry. Thus his fame has always stood higher in England and France than in Germany itself, where his lyric method, his self-consciousness, his cynicism in season and out of season, were less in

harmony with the literary traditions. As far as the development of the German lyric is concerned, it was Heine's particular achievement to introduce a new and invigorating element, the poetry of the sea.

As a prose writer, Heine's merits were very great. His work, it may be, was journalism, but it was journalism of a high order. His light fancy, his agile intellect, his straightforward, clear style stood him here in excellent stead. The prose writings of his French period mark, together with Börne's *Briefe aus Paris*, the beginning of a new era in German prose. Above all things, Heine was great as a wit and a satirist; here his powers were of the highest order. He combined the holy zeal and passionate earnestness of the "soldier of humanity" with the withering scorn and ineradicable sense of justice common to the leaders of the Jewish race. Heine felt that his real mission was to be a reformer, to restore, with instruments of war rather than of peace, "the interrupted order of the world." The more's the pity that his magnificent Aristophanic genius should have had so little room for its exercise, and have been frittered away in the petty squabbles of an exiled journalist.

BIBLIOGRAPHY.—The first collected edition of Heine's works was edited by A. Strodtmann in 21 vols. (1861–1866) good modern editions are edited by E. Elster (7 vols., 1887–1890), and O. Walzel, 10 vols., 1911 ff. His works have been translated into English by C. G. Leland and others (13 vols., 1892–1905), and the attempts to render the *Buch der Lieder* have been very numerous. See A. Strodtmann, *Heines Leben und Werke* (3rd ed., 1884); H. Hueffer, *Aus dem Leben H. Heines* (1878); and by the same author, *H. Heine: Gesammelte Aufsätze* (1906); W. Bölsche, *H. Heine: Versuch einer ästhetisch-kritischen Analyse seiner Werke und seiner Weltanschauung* (1888); G. Brandes, *Det unge Tyskland* (1890; Eng. trans., 1905); G. Karpeles, *H. Heine: aus seinem Leben und aus seiner Zeit* (1900); J. Legras, *H. Heine, poète* (1897); H. Lichtenberger, *H. Heine, penseur* (1905); M. J. Wolff, *Heinrich Heine*, Munich, 1923; *Heines Gespräche*, ed. by H. H. Houben, Frankfurt, 1926. An English biography by W. Stigand, *Life, Works and Opinions of Heinrich Heine*, appeared in 1875, but it has little value; there is also a short life by W. Sharp (1888). The essays on Heine by George Eliot and Matthew Arnold are well known. (J. W. FE.; J. G. R.)

HEINECCIUS, JOHANN GOTTLIEB (1681–1741), German jurist, was born on Sept. 11, 1681, at Eisenberg, Altenburg, and died at Halle, where he was professor of law, on Aug. 31, 1741. Heineccius endeavoured to treat law as a rational science, and not merely as an empirical art whose rules had no deeper source than expediency. Thus he continually refers to first principles, and he develops his legal doctrines as a system of philosophy. His most important work was *Elementa juris naturae et gentium* (1737; Eng. trans. by Turnbull, 2 vols., 1763).

His *Opera omnia* (9 vols., Geneva, 1771, etc.) were edited by his son J. C. G. Heineccius (1718–91).

HEINECKEN, CHRISTIAN HEINRICH (1721–1725), a child prodigy, was born on Feb. 6, 1721, at Lübeck. Able to speak at the age of ten months, by the time he was one year old he knew by heart the principal incidents in the Pentateuch. At two years of age he is said to have mastered sacred history; at three he was intimately acquainted with history and geography, ancient and modern, sacred and profane, besides being able to speak French and Latin; and in his fourth year he began the study of religion and church history. Crowds of people flocked to Lübeck to see the wonderful child, who was able to discuss what he had learnt. He began to learn writing, but died on June 22, 1725, at the age of four.

The Life, Deeds, Travels and Death of the Child of Lübeck were published in the following year by his tutor Schöneich. See also *Deutsche Bibliothek*, xvii., and *Mémoires de Trévoux* (Jan. 1731).

HEINEMANN, WILLIAM (1863–1920), British publisher, was born on May 18, 1863, at Surbiton and educated privately. He first studied music but, realizing that he could not hope to be in the front rank of musicians, started a publishing business. Amongst his earliest publications were Whistler's *Gentle Art of Making Enemies* (1890) and *Heinemann's International Library*, edited by Edmund Gosse. In 1897 he opened the series of *Short Histories of the Literatures of the World* with Gilbert Murray's *Ancient Greek Literature*. Heinemann's most conspicuous service to literature probably lies in his introduction to the English read-

ing public of Maeterlinck, Ibsen, Björnson, Tolstoy, Couperus and others. He died in London on Oct. 5, 1920.

See William Heinemann: *A Memoir*, ed. F. W. Whyte (1928).

HEINICKE, SAMUEL (1727-1790), the originator in Germany of systematic education for the deaf and dumb, was born on April 10, 1727, at Nautschütz, Germany, and died at Leipzig on April 30, 1790. In 1768, when living in Hamburg, he successfully taught a deaf and dumb boy to talk, following the methods prescribed by Amman in his book *Surdus loquens*, but improving on them. Recalled to his own country by the elector of Saxony, he opened in Leipzig, in 1778, the first deaf and dumb institution in Germany.

HEINRICH VON VELDEKE (fl. 12th century), German poet, was born near Maestricht, Holland, of a noble family. He served at the court of Cleves, where his poem *Eneit* (ed. by Behaghel, 1882) was begun. *Eneit* is modelled on a French version of the famous tale of the *Roman d'Enéas*, commonly attributed to Benoît de Ste. Mox (*q.v.*). Heinrich was in the service of Hermann, landgrave of Thuringia, and was present at the famous tournament at Mainz in 1184. He wrote his poem in Flemish, but the extant version is in the Thuringian dialect. It was begun some time after 1173, and completed in 1186, when he recovered it from a Count of Schwarzburg, by whom it had been stolen. The work is the first really important example of the courtly epic in German. Heinrich probably also wrote the *Legende von San Servaes* (St. Servatius). Gottfried of Strasbourg looked back to him as the father of German verse.

See C. Kraus, *Heinrich von Veldeke und die mhd. Dichtersprache*; F. Wilhelm, *Sanct Servatius* (1910); Jan van Dam, *Das Veldeke Problem* (1924).

HEINSE, JOHANN JAKOB WILHELM (1749-1803), German author, was born near Ilmenau in Thuringia on Feb. 16, 1749. As a law-student at Erfurt he became acquainted with Wieland and through him with "Father" Gleim, who in 1772 procured him the post of tutor in a family at Quedlinburg. In 1774 he went to Düsseldorf, where he helped J. G. Jacobi in editing the periodical *Iris*. He spent the years 1780-83 in Italy, and after his return to Germany became librarian to the archbishop of Mainz at Aschaffenburg, where he died on June 22, 1803. Both as novelist and art critic, Heinse had considerable influence on the romantic school.

Heinse's complete works (*Sämtliche Schriften*) were published by H. Laube in 10 vols. (Leipzig, 1838) and by C. Schüddekopf (Leipzig, 10 vols. 1902-13). See H. Pröhle, *Lessing, Wieland, Heinse* (1877), and J. Schober, *Johann Jacob Wilhelm Heinse, sein Leben und seine Werke* (Leipzig, 1882); K. D. Jessen, *Heinse's Stellung zur bildenden Kunst* (1903) and A. Jolivet, *W. Heinse, sa vie et son oeuvre jusqu'en 1787* (1922).

HEINSIUS or HEINS, DANIEL (1580-1655), one of the most famous scholars of the Dutch Renaissance, was born at Ghent on June 9, 1580, and died at The Hague on Feb. 25, 1655. The troubles of the Spanish war drove his parents to settle first at Veere in Zeeland, then in England, next at Ryswick and lastly at Flushing. In 1594 he was sent to the University of Franeker; six months later he went to Leyden, where he remained for the rest of his life, becoming professor and then librarian. There he studied under Joseph Scaliger, and there he found Marnix de St. Aldegonde, Janus Douza, Paulus Merula and others, and was soon taken into the society of these celebrated men as their equal. His proficiency in the classic languages won the praise of all the best scholars of Europe, and offers were made to him, but in vain, to accept honourable positions outside Holland. The remainder of his life is recorded in a list of his productions. He published his original Latin poems in three volumes—*Iambi* (1602), *Elegiae* (1603) and *Poëmata* (1605); his *Emblemata amatoria*, poems in Dutch and Latin, were first printed in 1604. In the same year he edited Theocritus, Bion and Moschus, having edited Hesiod in 1603. In 1609 he printed his Latin *Orations*. In 1610 he edited Horace, and in 1611 Aristotle and Seneca. In 1613 appeared in Dutch his tragedy of *The Massacre of the Innocents*; and in 1614 his treatise *De politica sapientia*. In 1616 he collected his original Dutch poems into a volume. He edited Terence in 1618, Livy in 1620, published his oration *De contemptu mortis* in 1621, and brought

out the *Epistles* of Joseph Scaliger in 1627.

HEINSIUS, NIKOLAES (1620-1681), Dutch scholar, son of Daniel Heinsius, was born at Leyden on July 20, 1620. His boyish Latin poem of *Breda expugnata* was printed in 1637, and attracted much attention. In 1642 he began his wanderings with a visit to England in search of mss. of the classics. From 1644 to 1653 he travelled without cessation between the principal libraries of Europe, everywhere collating mss. and taking philological and textual notes. He collected his Latin poems into a volume in 1653. His latest labours were the editing of Velleius Paterculus in 1678, and of Valerius Flaccus in 1680. He died at The Hague on Oct. 7, 1681. Nikolaes Heinsius was one of the purest and most elegant of Latinists, and if his scholarship was not quite so perfect as that of his father, he displayed higher gifts as an original writer.

HEINZE, RUDOLF (1865-1928), German politician, son of Max Heinze, the philosopher and the editor of Überweg's *Grundriss der Geschichte der Philosophie*, was born at Oldenburg on July 22, 1865. He served in the Saxon department of justice. He sat in the *Reichstag* (1907-11) with the National Liberals. For two years during the war (1916-18) he was under-secretary of State in the Turkish ministry of justice. After the revolution he joined the new German People's party, founded by Stresemann and other former National Liberals. In June 1920 he was asked to form a Government, but gave up the attempt since he could not secure the co-operation of the Social Democrats. He was minister of justice and vice-chancellor in the Fehrenbach (June 1920-May 1921) and Cuno (Nov. 1922-Aug. 1923) cabinets. He was nominated commissioner of the Reich in Saxony during the troubles of 1923, and in this capacity, supported by armed force, dismissed the Socialist-Communist Government. In 1926 he presided over the consular court in Egypt. Heinze died at Dresden on May 16, 1928.

HEIR, in law, technically one who succeeds, by descent, to an estate of inheritance, in contradistinction to one who succeeds to personal property, *i.e.*, next of kin. The rules regulating the descent of property to an heir will be found in the articles INHERITANCE; INTESTACY; SUCCESSION, etc.

An *heir apparent* is he whose right of inheritance is indefeasible, provided he outlives the ancestor, *e.g.*, an eldest or only son.

Heir general, or heir at law, he who after the death of his ancestor has, by law, the right to the inheritance.

Heir presumptive, one who is next in succession, but whose right is defeasible by the birth of a nearer heir.

Ultimate heir, he to whom lands come by escheat on failure of proper heirs. In Scots law the technical use of the word "heir" is not confined to the succession to real property, but includes succession to personal property as well, and this meaning is usual in many Continental codes which in this respect derive from the Roman law.

HEIRLOOM, strictly so called in English law, a chattel which by immemorial usage is regarded as annexed by inheritance to a family estate. Any owner of such heirloom may dispose of it during his lifetime, but he cannot bequeath it by will away from the estate. If he dies intestate it goes to his heir-at-law, and if he devises the estate it goes to the devisee. At the present time such heirlooms are almost unknown, and the word has acquired a secondary and popular meaning and is applied to furniture, pictures, etc., vested in trustees to hold on trust for the person for the time being entitled to the possession of a settled house. Such things are more properly called settled chattels. An heirloom in the strict sense is made by family custom, not by settlement. A settled chattel may, under the Settled Land Act, 1882, be sold under the direction of the court, and the money arising under such sale is capital money. By the Law of Property Act, 1925, pt. iv., settlements of realty and personal property are assimilated.

HEJAZ, THE, part of the independent kingdom of the Nejd and the Hejaz, and formerly under the old Ottoman empire a vilayet, which extended from Ma'an and 'Aqaba in the north to Hali Point on the Red sea coast on the south, and had its headquarters under a *Wali* at Mecca. The northern part of this territory is now included in Transjordan, the present northern bound-

dary running east from the Gulf of 'Aqaba in approximately 29° 35' N. as far as the 38° E. An indeterminate frontier with the Yemen forms its southern boundary. It is about 800 miles long and forms a narrow strip varying in depth from about 100 to 200 miles broad. The frontiers are indeterminate but the area probably does not exceed 150,000 sq.m. The population is under a million, some estimates giving the figure as low as 800,000. The majority of the inhabitants are Beduin, but the Muslim Holy Places of Mecca (70,000), the birthplace of the Prophet, Medina (15,000), the tomb of the Prophet, and Jidda (25,000) the port of Mecca, form considerable urban areas, greatly swollen by the annual influx of pilgrims, whose presence, much interrupted by the troublous events of the World War and post-war years, formed one of the most important parts of the commercial activities of the Hejaz. Medina produces dates, and Taif and the mountain oases fruit and honey; otherwise the products of the Hejaz are limited to such desert commodities as camels, horses, sheep and donkeys, and hides and wool.

Geography.—The Hejaz is divided into two zones, a coastal and an inland, by a range of mountains whose highest peaks probably reach 7,000 feet. Along the coastal strip there are a few settlements where the wadis (stony valleys) run from the hills on to the coastal plains, the most important of these wadis being the Wadi Hamd, which has three main sources, a northern, a central, on which Kheibar stands, and a southern, which supplies Medina. The valley of Medina can also be approached from the coast, either from Yenbo or Jidda by the Wadi es Safra. The wadis though liable to heavy floods are not permanent water supplies, but in places permanent springs are to be found, accompanied by the luxuriant vegetation of palm groves. Along the desolate coast of the Red sea there are a series of ports, of which Jidda, the port for Mecca, and Yenbo' (for Medina), are the most important. The others include Muwaila, Wejh, Rabigh, Lith and Qunfida. Wejh was formerly of importance as a port for Egyptian pilgrims, while in Roman times it was a post and the port of the Nabatean town of El Hajr.

The inland region consists of a series of basins, mostly with internal drainage, but in one or two cases, through the wadis mentioned above, the valleys communicate with the coastal region. Over this barren mountain country runs the old pilgrim way and the track of the Hejaz railway. North of Tebuk there is a large arid sandstone plateau, much eroded and carved into fantastic forms, whence it has been suggested the sands of the interior are derived, while along the western boundary of the Nejd plateau stretches the desolate volcanic lava bed of the Harrat. There are few settlements, apart from the oasis of Tebuk, and Al 'Ela (Egra of Ptolemy). The southern Hejaz is more fortunate in its water supplies. The city of Medina lies in the broad plain between the coastal range and the Nejd plateau. Here at an altitude of 2,500 feet there is an abundance of water, and dates, wheat and barley flourish. There is also a string of small settlements down to the port of Yenbo' along the Wadi es Safra. Mecca (*q.v.*) the chief town of the Hejaz lies to the south, about 48 m. from Jidda. From the hot lowland in which Mecca is situated the country rises up steeply to the Taif plateau, which owing to its altitude, about 6,000 ft., possesses a climate closely resembling the southern part of Arabia. On the northern edge of the plateau lies Jabal al Kura, a fertile well watered region, producing grain and fruit as well as dates. Taif itself lies in a sandy plain, surrounded by low mountains.

History.—The Hejaz, together with the other provinces of Arabia, which on the overthrow of the Baghdad Caliphate in 1258, by the Mongol invaders, had fallen under Egyptian domination, became, after the conquest of Egypt by the Turks in 1517, a dependency of the Ottoman empire. Although the title Caliph passed to Constantinople, the Government remained for the most part in the hands of the Sharifs of Mecca, until, in the religious upheavals at the beginning of the 19th century, the holy cities were pillaged by Wahhabis. The sultan accordingly entrusted to Mohammed Ali, viceroy of Egypt, the task of restoring peace. Eventually in 1817 the Wahhabis were defeated but not destroyed and their capital Deraiya, in Nejd, was taken by

Ibrahim Pasha. Egypt continued to administer the Hejaz until 1845, when the administration, under a wali was taken over by Constantinople directly. Owing to bad communications however it was difficult to control these distant and unruly parts of the Ottoman dominions and in 1900 Abdul Hamid decided to build a railway which should both improve communications and also avoid the Suez canal route. The first part of the line from Damascus to Ma'an was opened in 1904 and four years later the last section, terminating at Medina, was finished, and the Turkish control of the whole region considerably strengthened. It was however in this year (1908) that Husain ibn 'Ali was appointed Amir of Mecca, and this ambitious man at once began to oppose the Turkish plans, particularly in regard to the further extension of the railway to Mecca itself. The outbreak of the World War gave him further opportunities to satisfy his aspirations. So long as the railway was in the hands of the Turks, who had proclaimed a *Jihad*, the sea route to the east was exposed to attack; Great Britain therefore negotiated with Husain, Jidda was bombarded by British ships and that town and Mecca, and later Taif were taken from the Turks. Medina however held out and was defended by Fakhri Pasha till Jan. 1919, when he surrendered on receiving explicit orders from Constantinople. Meanwhile Col. T. E. Lawrence and Husain's third son, Amir Feisul, organized a brilliant guerrilla warfare against the railway and the northern positions of the Turks. Yenbo, Wejh and 'Aqaba (1917) fell and after the capture of Ma'an, Shaubak and Hejaz they reached a northern frontier which was kept until 1925. Husain assumed the title of king in 1916. He was represented by the Amir Feisul at the Peace Conference in Paris in 1919, and the Hejaz was admitted as an original member of the League of Nations, but eventually he refused to ratify the Peace Treaties. In the summer of 1921 Lawrence visited Jidda on behalf of the British Government to negotiate a treaty with King Husain, but as the latter would not accept the *de facto* position in Palestine negotiations broke down.

Meanwhile other factors were clouding the horizon. During the War Husain's reign had been mild, but he gradually became more and more autocratic and alienated the sympathies both of his neighbours and of his own people. He had undertaken, by the terms of the Peace Treaties to maintain the annual pilgrimage but his administration of the arrangements for the reception of the pilgrims was very unsatisfactory. Government departments were corrupt, even the army was not properly cared for and the Air Force which had been organized lapsed more than once until revived once more by his successor. On the other hand his transport fleet and system of wireless communication were satisfactory and proved of value. It was under such conditions that the Hashimite dynasty faced its new perils. Early in 1919 King Husain's relations with Ibn Sa'ud became strained owing to a dispute over Khurma oasis. His forces were defeated by the Wahhabis at Turaba and in 1922 Ibn Sa'ud occupied Khaibar and Taima. Meanwhile negotiations with the British Government were kept alive by Dr. Naji al Asil, the Hashimite representative in London and were not finally abandoned till the outbreak of war between Nejd and Hejaz in 1924. King Husain, however, refused until it was too late to send a representative to the conference summoned by the British Government at Kuwait, but at the beginning of 1924 visited Transjordan where he assumed the title of Khalifa and returned to Mecca to attempt to obtain recognition of his new position by the Muslim world. This brought matters to a head and Ibn Sa'ud declared war on the Hejaz. Taif fell without any resistance and Husain abdicated in favour of his son 'Ali. The latter evacuated Mecca and attempted to raise an army. Jidda was organized for defence. Ibn Sa'ud occupied Mecca in Dec. 1924 and at the beginning of the year attacked Jidda without any success. The siege was temporarily raised in June. In the meantime however considerable success attended his arms, the ports fell one by one, and at the beginning of December Medina, and shortly afterwards Wejh surrendered. The end was not far off. King Ali abdicated a fortnight later. Jidda and Yenbo' surrendered and Ibn Sa'ud was master of the Hejaz. He was crowned king at Mecca in Jan. 1926. Certain changes have taken

place in the actual political boundaries. Asir, the coastal strip south of Hali Point, was in a difficult position between her two powerful neighbours, Ibn Sa'ud and the Imam of the Yeman. In Oct. 1926 the former was definitely recognized as paramount sovereign. The annexation on the other hand by the British Government, in July 1925, of the 'Aqaba-Ma'an region to the Palestine mandated territory deprived the Hejaz territory won during the war. In this region alone is the Hejaz railway, which made this land so important during the World War, in working order. The southern section was put out of order during the Wahhabi siege of Medina and has never been repaired. In May 1927 a treaty was signed between Great Britain and Ibn Sa'ud at Jidda. Great Britain agreed to recognize Ibn Sa'ud's independence. He therefore occupies a dominant position in Arabia from his headquarters at Riyadh, holding the crown of Nejd and of the Hejaz. In Jan. 1928 the old currency was superseded by a silver currency of Riyals (10=£1). (For bibliography see ARABIA.)

HEJIRA or **HEGIRA**, the name of the Mohammedan era (Arab, *hijra*, flight). It dates from 622, the year in which Mohammed "fled" from Mecca to Medina to escape the persecution of his kinsmen of the Koreish tribe. The years of this era are distinguished by the initials "A.H." (*anno hegirae*). The Mohammedan year is a lunar one, about 11 days shorter than the Christian. Although Mohammed himself appears to have dated events by his flight, it was not till later that the actual era was systematized by Omar, the second caliph (see CALIPHATE), as beginning from the first day of Muharram (the first lunar month of the year) which in that year (639) corresponded to July 16. The term *hejira* is also applied in its more general sense to other "emigrations" of the faithful, e.g., to that to Abyssinia (see MOHAMMED), and to that of Mohammed's followers to Medina before the capture of Mecca. These latter are known as *Muhajirun*.

BIBLIOGRAPHY.—See the article MOHAMMED, and also cf. Wüstenfeld, *Vergleichungstabellen der muhammedanischen und christlichen Zeitrechnung* (2nd ed., Leipzig, 1903); D. Nielson, *Die altarabische Mondreligion* (Strassburg, 1904); Hughes, *Dictionary of Islam*, s.v. "Hijrah."

HEL or **HELA**, in Scandinavian mythology, goddess of the dead, a child of Loki and the giantess Angurboda, dwelt beneath the roots of the sacred ash, Yggdrasil (*q.v.*), and ruled the nine worlds of Helheim. In early myth all the dead went to her: in later legend only those who died of old age or sickness; she then became synonymous with suffering and horror.

HELDENBUCH, DAS, the title under which a large body of German epic poetry of the 13th century has come down to us. The subjects of the individual poems are taken from national German sagas which originated in the epoch of the Migrations (*Völkerwanderung*), although doubtless here, as in all purely popular sagas, motives borrowed from the forces and phenomena of nature were, in course of time, woven into events originally historical. The poems of the *Heldenbuch* belong to two cycles, (1) the Ostrogothic saga of Ermannich, Dietrich of Bern (*i.e.*, Dietrich of Verona, Theodoric the Great) and Etzel (Attila), and (2) the cycle of Hugdietrich, Wolfdietrich and Ortnit, which was probably of Franconian origin. Dietrich of Bern (*q.v.*) the central figure of the more important group, was the ideal type of German mediaeval hero. Of the romances of this group, the chief are *Biterolf und Dietlieb*, evidently the work of an Austrian poet. *Der Rosengarten* tells of the conflicts round Kriemhild's "rose garden" in Worms—conflicts from which Dietrich always emerges victor, even when he is confronted by Siegfried himself. *Laurin und der kleine Rosengarten* deals with the adventures of Dietrich and his henchman Witege with the wily dwarf Laurin, who watches over another rose garden, that of Tyrol. Other elements of the Dietrich saga are represented by *Alpharts Tod*, *Dietrichs Flucht*, and *Die Rabenschlacht* ("Battle of Ravenna"). Of these, the first is much the finest poem of the entire cycle. The other two Dietrich epics belong to the end of the 13th century—the author being an Austrian, Heinrich der Vogler—and show the decay that had by this time set in in Middle High German poetry.

The second cycle of sagas is represented by several long ro-

mances, all of them unmistakably "popular" in tone. The epics of this group are *Ortnit (q.v.)*, *Hugdietrich*, *Wolfdietrich (q.v.)*. Although many of the incidents and motives of this cycle are drawn from the best traditions of the Heldensage, its literary value is not very high.

BIBLIOGRAPHY.—This collection of romances was one of the first German books printed. The date of the first edition is unknown, but the second edition appeared in the year 1491 and was followed by later reprints in 1509, 1545, 1560 and 1590. The last of these forms the basis of the text edited by A. von Keller for the Stuttgart *Literarische Verein* in 1867. In 1472 the *Heldenbuch* was remodelled in rough *Knittelvers* or doggerel; this version was printed by F. von der Hagen and S. Prümmer in their *Heldenbuch* (1820–25). *Das Heldenbuch*, which F. von der Hagen published in 2 vols. in 1855, was the first attempt to reproduce the original text by collating the mss. A critical edition, was published in 5 vols. by O. Jänicke, E. Martin, A. Amelung and J. Zupitza at Berlin (1866–73). A selection, edited by E. Henrici, will be found in Kürschner's *Deutsche Nationalliteratur*, vol. 7 (1887). Recent editions have appeared of *Der Rosengarten* and *Laurin*, by G. Holz (1893 and 1897). All the poems have been translated into modern German by K. Simrock and others. See F. E. Sandbach, *The Heroic Saga-Cycle of Dietrich of Bern* (1906). The literature of the *Heldensage* is very extensive. See especially W. Grimm, *Die deutsche Heldensage*, 3rd ed. (1889); L. Uhland, "Geschichte der deutschen Poesie im Mittelalter," *Schriften*, vol. i. (1866); O. L. Jiriczek, *Deutsche Heldensage*, vol. i. (1898); and especially B. Symons, "Germanische Heldensage," in Paul's *Grundriss der germanischen Philologie*, 2nd ed. (1898).

HELDER, seaport in province of North Holland, 51 m. by rail N.N.W. of Amsterdam. Pop. (1926) 29,897. It is situated on the Marsdiep, the channel separating the island of Texel from the mainland and the main entrance to the Zuider Zee. It is the terminus of the North Holland canal from Amsterdam, and an important naval and military station. On the east side of the town is the harbour with naval wharves and magazines, wet and dry docks. The great sea-dike stretches from Nieuwe Diep to Fort Erprins, a distance of about 5 m. It descends at an angle of 40° for 200 ft. into the sea. The town is fortified and there is a permanent garrison, while the province can be flooded from this point. It has a meteorological observatory, a zoological station and a lighthouse.

HELEN, in Greek mythology, daughter of Zeus by Leda (wife of Tyndareus, King of Sparta) or by Nemesis: sister of Polydeuces and Clytaemnestra, and wife of Menelaus (Gr. Ἑλένη). She was the most beautiful woman in Greece, and indirectly the cause of the Trojan war. When a child she was carried off from Sparta by Theseus to Attica, but was recovered and taken back by her brothers. When she grew up, the most famous of the princes of Greece sought her hand in marriage and her father's choice fell upon Menelaus. During her husband's absence she was induced by Paris, son of Priam, with the connivance of Aphrodite, to flee with him to Troy. After the death of Paris she married his brother Deiphobus, whom she is said to have betrayed into the hands of Menelaus at the capture of the city (Aeneid vi. 517ff). Menelaus thereupon took her back, and they returned together to Sparta, where they lived happily till their death and were buried at Therapnae in Laconia. According to another story, Helen survived her husband, and was driven out by her stepsons. She fled to Rhodes, where she was hanged on a tree by her former friend Polyxo, to avenge the loss of her husband Tlepolemus in the Trojan War (Pausanias iii. 19). After death, Helen was said to have married Achilles in his home in the island of Leukē. According to Stesichorus, Paris, on his voyage to Troy with Helen, was driven ashore on the coast of Egypt, where King Proteus detained the real Helen in Egypt, while a phantom Helen was carried off to Troy; the real one was recovered by her husband after the war. (Herodotus ii. 112–120; Euripides, *Helena*). Helen was worshipped as the goddess of beauty at Therapnae in Laconia, where a festival was held in her honour. At Rhodes she was worshipped under the name of Dendritis (the tree goddess), where the inhabitants built a temple in her honour. We have thus an epic heroine Helen and a goddess Helen; the relations between the two are a problem as yet unsolved. Like her brothers, the Dioscuri, she was a patron deity of sailors.

See R. Englemann in Roscher's *Lexikon*; O. Gruppe, *Griechische Mythologie*, i. 163.

HELENA, ST. (c. 247–c. 327) the wife of the emperor Constantius I. Chlorus, and mother of Constantine the Great. She was a woman of humble origin, born probably at Drepanum, a town on the Gulf of Nicomedia, which Constantine named Helenopolis in her honour. Very little is known of her history. It is certain that, at an advanced age, she undertook a pilgrimage to Palestine, visited the holy places, and founded several churches. She was still living at the time of the murder of Crispus (326). Constantine had coins struck with the effigy of his mother. The name of Helena is intimately connected with the commonly received story of the discovery of the Cross. But the accounts which connect her with the discovery are much later than the date of the event. The Pilgrim of Bordeaux (333), Eusebius, and Cyril of Jerusalem were unaware of this important episode in the life of the empress. It was only at the end of the 4th century and in the West that the legend appeared.

The principal centre of the cult of St. Helena in the West seems to be the abbey of Hautvilliers, near Reims, where since the 9th century they have claimed to be in possession of her body. In England legends arose representing her as the daughter of a prince of Britain. Following these Geoffrey of Monmouth makes her the daughter of Coel, the king who is supposed to have given his name to the town of Colchester. These legends have doubtless not been without influence on the cult of the saint in England, where a great number of churches are dedicated either to St. Helena alone, or to St. Cross and St. Helena. Her festival is celebrated in the Latin Church on the 18th of August. The Greeks make no distinction between her festival and that of Constantine, the 21st of May.

See *Acta sanctorum*, Augusti iii. 548–580; Tixeront, *Les Origines de l'église d'Édesse* (Paris, 1888); F. Arnold-Foster, *Studies in Church Dedications or England's Patron Saints*, i. 181–189, iii. 16, 365–366 (1899). (H. DE.)

HELENA, a city of Arkansas, U.S.A., on the Mississippi river, 55m. (in a bee-line) below Memphis; the county seat of Phillips county. It is served by the Illinois Central, the Missouri and Northern Arkansas, and the Missouri Pacific railways, and is at the head of navigation for ocean-going steamers. The population was 9,112 in 1920 (53% negroes). The city is built partly on a ridge 150ft. above sea-level, and is well protected by levees. It is an important shipping point for cotton, cotton-seed products, lumber and lumber products from its own plants. Helena was founded about 1821. During the Civil War it was of considerable strategic importance. It was occupied and strongly fortified by Union troops in July, 1862, and on July 4, 1863, when attacked by the Confederates, was the scene of hot fighting, resulting in the loss of a fifth of the Confederate force.

HELENA (hēl'-ē-na), the capital city of Montana, U.S.A., the county seat of Lewis and Clark county; near the centre of the

BY COURTESY OF THE CHAMBER OF COMMERCE, HELENA, MONTANA
THE STATE CAPITOL OF MONTANA, AT HELENA

western part of the State, at the eastern foot of the Continental Divide. It is on Federal highway 91; is served by the Great Northern and the Northern Pacific railways; and has a municipal airport. The population was 12,037 in 1920 and was estimated locally at 13,500 in 1928.

Helena is delightfully situated, at an altitude of 3,955ft. in the hollow of the Prickly Pear valley, a rich agricultural region surrounded by rolling hills and lofty mountains. It is an important touring centre. Mt. Helena forms a background for the city. The

State capitol has a fine site, with open country in two directions. In the State library are files of scarce old newspapers and other valuable material on the early history of the region. Mt. St. Charles college for men (Roman Catholic) was established in 1909. Intermountain Union college was formed in 1923 by the consolidation of the College of Montana (Presbyterian; established in 1878 at Deer Lodge) and Montana Wesleyan college (Methodist; established at Helena in 1889). There is a U.S. assay office in Helena. At East Helena (pop. 1920, 1,109) are quartz crushers and smelters and a large zinc reduction plant of the Anaconda Mining company (built in 1927).

Gold was discovered in Last Chance Gulch, now the main street of Helena, in July 1864. About the same time silver-bearing lead ores were found 20m. S.E., and a little later gold-bearing quartz veins were found 5m. S. On Oct. 30, 1864, a town was organized, which within two years had a population of 7,500. Gold to the value of \$16,000,000 was taken from the gravel of Last Chance Gulch, mostly before 1868. By 1870 the placers were exhausted, and a period of stagnation set in, lasting until the Northern Pacific railway reached this point. On July 4, 1883, the first regular train left the city, carrying 1,000,000lb. of silver bullion. The total yield of gold, silver, lead and copper has totalled between \$150,000,000 and \$200,000,000. Helena was burned down in 1869 and in 1874. It was made the capital of the Territory in 1874 and in 1881 was chartered as a city.

HELENSBURGH, a burgh of barony and police burgh and watering-place in Dumbartonshire, Scotland, on the north shore of the Firth of Clyde, opposite Greenock, 24 m. N.W. of Glasgow by the L.N.E.R., with another station at Upper Helensburgh. Pop. (1921) 9,701. There is steamer communication with Gareloch-head, Dunoon and other pleasure resorts on the western coast, and with Greenock, Glasgow, etc., from the old pier at Helensburgh. In 1776 the site began to be built upon, and in 1802 the town, named after Lady Helen, wife of Sir James Colquhoun of Luss, the ground landlord, was erected into a burgh of barony.

HELENUS, in Greek legend, son of Priam and Hecuba, and twin brother of Cassandra. In Homer, he appears as a seer and warrior. In later writers it is related that he and his sister fell asleep in the temple of Apollo Thymbraeus and that snakes came and cleansed their ears, whereby they obtained the gift of prophecy, and were able to understand the language of birds. After the death of Paris, because Helen rejected him for Deiphobus, Helenus withdrew in indignation to Mt. Ida, where he was captured by the Greeks; in other accounts he was captured by a stratagem of Odysseus, or surrendered voluntarily in disgust at the treacherous murder of Achilles (*q.v.*). He informed the Greeks of the "fates" of Troy, (Palladium, arrows of Heracles, arrival of Neoptolemus, *see* Troy) and advised the building of the Wooden Horse.

After the capture of Troy he and his sister-in-law Andromache accompanied Neoptolemus (Pyrrhus) as captives to Epirus, where Helenus persuaded him to settle. After the death of Neoptolemus, Helenus married Andromache and became ruler of the country. He was the reputed founder of Buthrotum and Chaonia, named after a brother or a companion, whom he had accidentally slain while hunting. He was said to have been buried at Argos, where his tomb was shown.

See Homer, *Iliad*, vi. 76, vii. 44, xii. 94, xiii. 576; Sophocles, *Philoctetes*, 604, who probably follows the *Little Iliad* of Lesches; Pausanias i. 11, ii. 23; Conon, *Narrationes* 34; Dictys Cretensis, iv. 18; Virgil, *Aeneid* iii. 294–490; Servius on *Aeneid* ii. 166, iii. 334.

HELFFERICH, KARL (1872–1924), German financier and politician, was born in Neustadt-on-the-Havel on July 22, 1872. In 1901 he became a professor of political science in Berlin, and in 1906 went to Constantinople as manager of the Anatolian Railway. He returned to Berlin in 1908 to take up the chairmanship of the Deutsche Bank. In 1913 he was the chief German delegate at the Paris conference for the settlement of Balkan financial affairs. In 1915 Helfferich was appointed secretary of state for the Imperial treasury, where he followed the principle of defraying the cost of the War by borrowing rather than by fresh taxation, relying on a final German victory. In June 1916

he left the treasury for the home office. In June 1918 he was appointed to succeed Count Mirbach, who had been assassinated, as Germany's representative in Moscow. He remained in Moscow for three months, returning to Berlin in August to conduct the economic and industrial demobilization of Germany after the Armistice. He devoted himself thenceforward principally to financial questions. In 1923 he secured the currency of the Renten mark, and then fought against the Government policy of fulfilment of treaty obligations. He was fatally injured April 23, 1924.

His publications include: *Das Geld* (1903, 6th ed. 1923); *Deutschlands Volkswohlstand 1888-1913* (1913, 7th ed. 1917, trs. 1913); *Der Weltkrieg* (3 vols. 1919); *Die Politik der Erfüllung* (1922); *Die deutsche Türkenpolitik* (1921), *Georg von Siemens, ein Lebensbild* (3 vols., 1922-23). See K. von Lumm, *Helferich als Währungspolitiker und Gelehrter* (1926).

HELGAUD or **HELGAUDUS** (d. c. 1048), French chronicler, was a monk of the Benedictine abbey of Fleury. Little else is known about him save that he was chaplain to the French king, Robert II. the Pious, whose life he wrote. The only extant ms. of this *Epitoma vitae Roberti regis* is in the Vatican. Editions have been printed by J. P. Migne in the *Patrologia Latina*, tome cxli. (Paris, 1844); and by M. Bouquet in the *Recueil des historiens des Gaules*, tome x. (Paris, 1760).

See *Histoire littéraire de la France*, tome vii. (1865-1869); and A. Molinier, *Les Sources de l'histoire de France*, tome ii. (1902).

HELGESEN, POVL¹, Danish humanist, was born at Varberg in Halland about 1480, of a Danish father and a Swedish mother. Helgesen was educated first at the Carmelite monastery of his native place and afterwards at another monastery at Elsinore, where he devoted himself to humanistic studies and adopted Erasmus as his model. As lector at the university of Copenhagen, gathered round him a band of young enthusiasts, the future leaders of the Danish Reformation. But Helgesen desired an orderly, methodical, rational reformation, and denounced Luther, whose ablest opponent in Denmark he became, as a hot-headed revolutionist. Helgesen's denunciation of Christian II. made it necessary for him to leave the capital. Under Frederick I. (1523-1533) he returned to Copenhagen and resumed his chair at the university, becoming soon afterwards provincial of the Carmelite Order for Scandinavia. Helgesen was attacked as bitterly by the Catholics as by the Protestants. In October 1534, however, Helgesen issued an eirenicon in which he attempted to reconcile the two contending confessions. After that every trace of him is lost. Helgesen was indisputably the greatest master of style of his age in Denmark. His historical works, *Danmark's Kongers Historie* and *Skibby Kröniken*, have some importance.

See Ludwig Schmitt, *Der Karmeliter Paulus Helä* (Freiburg, 1893); *Danmarks Riges Historie* (Copenhagen, 1897-1905), vol. iii.

HELIACAL, relating to the sun ($\eta\lambda\iota\omicron\varsigma$), a term applied in the ancient astronomy to the first rising of a star which could be seen after it emerged from the rays of the sun, or the last setting that could be seen before it was lost from sight by proximity to the sun.

HELIAND. The 9th-century poem on the Gospel history, to which its first editor, J. A. Schmeller, gave the appropriate name of *Heliand* (the word used in the text for "Saviour"), is, with the fragments of a version of the story of Genesis believed to be by the same author, all that remains of the poetical literature of the Old Saxons, i.e., the Saxons who continued in their original home. It contained when entire about 6,000 lines, and portions of it are preserved in four mss. The poem is based on the pseudo-Tatian's harmony of the Gospels, and shows acquaintance with the commentaries of Alcuin, Baeda and Rabanus Maurus (whose commentary on the gospel of Matthew was finished about 820).

A part of the Genesis poem, as is mentioned in the article CAEDMON, is extant only in an Old English translation, but portions have been preserved in the original language in the same Vatican ms. that includes a fragment of the *Heliand*. In the one language or the other, there are in existence the following three fragments: (1) The passage which appears as

¹He wrote his name Heliae or Eliae.

lines 235-851 in the so-called "Caedmon's *Genesis*," on the revolt of the angels and the temptation and fall of Adam and Eve. Of this the part corresponding to lines 790-820 exists also in the original Old Saxon. (2) The story of Cain and Abel, in 124 lines. (3) The account of the destruction of Sodom, in 187 lines. The main source of the *Genesis* is the Bible, but considerable use was made of two Latin poems by Alcimius Avitus, *De initio mundi* and *De peccato originali*.

The two poems give evidence of genius and trained skill. Within the limits imposed by the nature of his task, the poet's treatment of his sources is remarkably free, the details unsuited for poetic handling being passed over, or, in some instances, boldly altered. In the *Heliand* the Saviour and His Apostles are conceived as a king and his faithful warriors, and the use of the traditional epic phrases appears to be the spontaneous mode of expression of one accustomed to sing of heroic themes. The *Genesis* fragments have less of the heroic tone, except in the splendid passage describing the rebellion of Satan and his host. It is noteworthy that the poet, like Milton, sees in Satan no mere personification of evil, but the fallen archangel, whose guilt could not obliterate all traces of his native majesty.

Such external evidence as exists bearing on the origin of the *Heliand* and the companion poem is contained in a Latin document printed by Flacius Illyricus in 1562. This is in two parts; the one in prose, entitled (perhaps only by Flacius himself) "*Praefatio ad librum antiquum in lingua Saxonica conscriptum*"; the other in verse, headed "*Versus de poeta et Interpreta hujus codicis*." The *Praefatio* begins by stating that the emperor, Ludwig the Pious, commanded a certain Saxon, who was esteemed as an eminent poet, to translate the Old and New Testaments. The poet rendered into verse all the most important parts of the Bible with admirable skill, dividing his work into *vitteas*, a term which, the writer says, may be rendered by "*lectiones*" or "*sententias*." The *Praefatio* goes on to say that it was reported that the poet, till then knowing nothing of the art of poetry, had been admonished in a dream to turn into verse the precepts of the divine law, which he did with so much skill that his work surpasses in beauty all other German poetry. The *Versus* practically reproduces in outline Baeda's account of Caedmon's dream, without mentioning the dream, but describing the poet as a herdsman, and adding that his poems, beginning with the creation, relate the history of the five ages of the world down to the coming of Christ.

As the *Praefatio* speaks of the emperor Ludwig in the present tense, the former part of it at least was probably written in his reign, i.e., not later than A.D. 840. The general opinion of scholars is that the latter part, which represents the poet as having received his vocation in a dream, is by a later hand, and that the sentences in the earlier part which refer to the dream are interpolations. The date of these additions, and of the *Versus*, is of no importance, as their statements are incredible. That the author of the *Heliand* was, so to speak, another Caedmon—an unlearned man who turned into poetry what was read to him from the sacred writings—is impossible, because in many passages the text of the sources is so closely followed that it is clear that the poet wrote with the Latin books before him. On the other hand, there is no reason for rejecting the almost contemporary testimony of the first part of the *Praefatio* that the author of the *Heliand* had won renown as a poet before he undertook his great task at the emperor's command.

BIBLIOGRAPHY.—The first complete edition of the *Heliand* was published by J. A. Schmeller in 1830; the second volume, containing the glossary and grammar, appeared in 1840. The standard edition is that of E. Sievers (1877), in which the texts of the Cotton and Munich mss. are printed side by side. Other useful editions are those of M. Heyne (3rd ed., 1903), O. Behaghel (1882) and P. Piper (1897, containing also the Genesis fragments). The fragments of the *Heliand* and the *Genesis* contained in the Vatican ms. were edited in 1894 by K. Zangemeister and W. Braune under the title *Bruchstücke der altsächsischen Bibeldichtung*. See also E. Windisch, *Der Heliand und seine Quellen* (1868); E. Sievers, *Der Heliand und die angelsächsische Genesis* (1875); R. Kögel, *Deutsche Literaturgeschichte*, Bd. i. (1894) and *Die altsächsische Genesis* (1895); R. Kögel and W. Bruckner, "Althoch- und altniederdeutsche Literatur," in

Paul's *Grundriss der germanischen Philologie*, Bd. ii. (2nd ed., 1901), which contains references to many other works; Hermann Collitz, *Zum Dialekte des Heliand* (1907). (H. Br.; X.)

HELICON, a mountain range in Greece, celebrated in classical literature as an abode of the Muses, is situated between Lake Copais and the Gulf of Corinth. The highest summit, the present Palaeovouni (old hill), rises to the height of about 5,000 ft. On the fertile eastern slopes stood a temple and grove sacred to the Muses, and adorned with statues, which, taken by Constantine the Great to beautify his new city, were consumed there by a fire in A.D. 404. Hard by were the fountains Aganippe and Hippocrene, the latter created by the tread of the winged horse Pegasus. At the neighbouring Ascrea dwelt the poet Hesiod, a fact which probably enhanced the poetic fame of the region. Pausanias describes Helicon as the most fertile mountain in Greece; neither poisonous plant nor serpent was to be found on it, while many of its herbs possessed miraculous virtue. His description makes it possible to reconstruct the classical topography and French excavators have discovered the temple of the Muses and a theatre.

See W. M. Leake, *Travels in Northern Greece* (vol. ii., 1835); J. G. Frazer, *Pausanias*, v. 150.

HELICON, the circular form of the B flat contrabass tuba used in military bands, worn round the body, with the enormous bell resting on the left shoulder and towering above the head of the performer, (Fr. *hélicon*, *bombardon circulaire*; Ger. *Helikon*). The pitch of the helicon is an octave below that of the euphonium.

HELICOPTER. A flying machine whose supporting surfaces are rotated mechanically, being equivalent to an air-screw (or air-screws) so arranged as to give an approximately vertical thrust. Since such a system does not derive its lift from a motion of the whole machine through the air (contrast both the ordinary aeroplane and the GYROPLANE, *q.v.*) it is in principle capable of hovering, and of rising or descending vertically. Schemes for helicopters are found throughout the literature of flying, from the earliest times, but there are few records of actual construction, and none of successful flight. The device is in fact extravagant of power. In the light of modern knowledge one horse-power cannot be expected to lift more than about 15 lb. The whole of the power of a modern commercial aeroplane arranged as a helicopter would be needed merely to sustain it, leaving nothing to raise or propel it.

The most hopeful line of development for the helicopter is along the lines of the gyroplane. A mechanical drive to the rotating wings will enable the gyroplane to rise from the ground after a shorter run than is necessary for the "autogiro," though it is unlikely that, for a given expenditure of power the rate of climb will be thereby improved. It may be possible to dispense with the driving air-screw of the gyroplane, devoting the whole power to rotating wings and obtaining the thrust required for forward motion by inclining their axis. The essential difficulty is in the control, and as with the aeroplane success will not be attained until the problem of control has been solved. Failure of the power plant will force a helicopter to descend, but need not result in a catastrophe. Given effective control over the inclination of the axis of the wings, all the ordinary manoeuvres of a normal aeroplane about to land may be regarded as within its powers, with the additional possibility of a steep final descent at a slow speed.

It is unlikely that the helicopter, even as visualized above, will equal the aeroplane in performance, or in the proportion of its total weight available for load. If it ultimately displaces the aeroplane for certain purposes, it will be entirely on account of the gain in safety in which the practical realization of its essential feature—lift not dependent on forward speed—will result.

(W. S. F.)

HELIGOLAND (Ger. *Helgoland*), an island of Germany, in the North Sea, lying off the mouths of the Elbe and the Weser, 28 m. from the nearest point in the mainland. Pop. (1925) 2,588. The generally accepted derivation of Heligoland (or Helgoland) from *Heiligeland*, *i.e.*, "Holy Land," seems doubtful. According to northern mythology, Forseti, a son of Balder and Nanna, the god of justice, had on the island a temple subsequently destroyed by St. Ludger. This legend may have given rise to the derivation

"Holy Land." The more probable etymology, however, is that of Hallaglun, or Halligland, *i.e.*, "land of banks, which cover and uncover." Here Hertha, according to tradition, had her great temple, and hither came from the mainland the Angles to worship at her shrine, and on this isle St. Willibrord in the 7th century first preached Christianity. For its ownership, before and after that date, many sea-rovers have fought until it finally became a fief of the dukes of Schleswig-Holstein. The island was a Danish possession in 1807, when the English seized and held it until it was formally ceded to them in 1814. A British possession until 1890, it was ceded in that year to Germany, and since 1892 has formed part of the Prussian province of Schleswig-Holstein. It consists of two islets, the main, or Rock island, and the small Dünen-Insel, a quarter of a mile to the east, connected by a neck of land until 1720, when they were severed by a violent irruption of the sea. The former is nearly triangular in shape and is surrounded by steep red cliffs, the only beach being the sandy spit near the south-east point, with the landing-stage. The cliffs are worn into caves, arches and columns. The impression made by the red cliffs, fringed by a white beach and supporting the green Oberland, is commonly believed to have suggested the national colours, red, white and green, or, as the old Frisian rhyme goes:—

"Grön is dat Land,
Rood is de Kant,
Witt is de Sand,
Dat is de Flagge vun't hillige Land."

The lower town of Unterland, on the spit, and the upper town, or Oberland, situated on the cliff above, are connected by a wooden stair and a lift. There is a powerful lighthouse, and after cession by Great Britain to Germany, the main island was strongly fortified, but the fortifications were demolished according to the terms of the Treaty of Versailles. Inside the Dünen-Insel the largest ships can ride safely at anchor, and take in coal and other supplies. The greatest length of the main island, which slopes somewhat from west to east, is just a mile, and the greatest breadth less than a third of a mile, its average height 198 ft., and the highest point, crowned by the church, 216 feet. The Dünen-Insel is a sand-bank protected by groynes, and here the numerous visitors bathe. Most of the houses are built of brick, but some are of wood. In 1892 a biological institute, with marine museum and aquarium (1900) attached, was opened.

German is the official language, though among themselves the natives speak a dialect of Frisian, barely intelligible to the other islands of the group. There is regular communication with Bremen and Hamburg.

The winters are stormy. May and the early part of June are wet and foggy, so that few visitors arrive before the middle of the latter month.

HELIGOLAND BIGHT. On Aug. 28, 1914, a sweep by the British light naval forces into the Heligoland Bight brought about the first serious contact between the opposing naval forces during the World War. The action began at daylight, developed into a series of confused fights, in misty weather upon a glassy-smooth sea, and lasted until 1.30 P.M., when, the sweep having been completed, Vice-Admiral Sir David Beatty withdrew his forces. The day ended to the distinct advantage of the British, who had one cruiser ("Arethusa") and three destroyers damaged with a total casualty list of 35 killed and 40 wounded. The Germans lost 1,242 officers and men, killed, wounded, and prisoners; three cruisers ("Mainz," "Cöln," and "Ariadne") and one destroyer (V. 187) were sunk; one cruiser ("Frauenlob") was badly crippled, and there was unreported damage to other cruisers and torpedo craft.

THE PLAN OF OPERATIONS

From the first days of the war a watching patrol, maintained by British submarines off the entrance to the German ports, had obtained an accurate knowledge of the routine movements of the German patrols. Against these patrols the sweep was planned, to be carried out by light forces, upon a day when the German heavy ships would be tide-bound until afternoon, inside the Jade river bar. In the original plan of the operation, Comm. Roger Keyes, commanding the submarine flotilla (eight submarines of the "D"

and "E" class and the destroyers "Lurcher" and "Firedrake") was to place an inner line of three submarines close to Heligoland, with orders to remain submerged until after a certain hour. An outer line of three submarines was stationed 40m. to the westward, instructed to try and draw the enemy destroyers to sea. Two other submarines were to watch the entrance to the Ems river.

The destroyer force, under Comm. Reginald Tyrwhitt, consisted of the "Arethusa" with the 3rd flotilla (16 t.b.d.'s) and the "Fearless" (Capt. Blunt) with the 1st flotilla (15 t.b.d.'s). The battle-cruisers "Invincible" (Rear-Admiral Sir Archibald Moore) and "New Zealand" were to act in support and were to meet the destroyer force to the south-east of the Dogger Bank on the evening of the 27th. Whilst the submarines were taking up their positions the cruisers and destroyers were to steer for a point 75m. N.N.W. from Heligoland, so as to arrive there by daylight on the 28th. The flotillas were then to sweep south and west through the Bight to cut off the German destroyers on their return from their nightly patrol. The two battle-cruisers would be in support to seaward and, away to the west, off the Terschilling light, an armoured cruiser force under Rear-Admiral Christian was held in reserve.

Such was the original plan. It was modified at the last moment on account of the diversion at Ostende. A brigade of Royal Marines was landing at that place on the 26th, under cover of the ships of the channel squadron, and a countermove by the German high sea fleet seemed likely. Therefore, support from the grand fleet was arranged and Admiral Jellicoe sent Vice-Admiral Beatty south in command of a force consisting of the battle-cruisers "Lion," "Queen Mary," and "Princess Royal" and Comm. Goodenough's squadron of six light cruisers ("Southampton," "Falmouth," "Birmingham," "Nottingham," "Lowestoft," and "Liverpool"). Beatty joined the "Invincible" off the Dogger Bank on the evening of the 27th and Goodenough's cruisers were sent on towards the destroyers' daylight position. Unfortunately, a wireless message, informing Tyrwhitt and Keyes of the change of plan, miscarried and neither commodore was aware of the presence of the northern forces until after the operation had commenced.

At about 3.30 A.M. Goodenough's cruisers came into contact with Tyrwhitt's destroyers and were at first mistaken for an enemy: recognition signals, however, averted the danger of an attack and at 4.0 A.M. Tyrwhitt, with his destroyers, began his run to the south. Goodenough's six cruisers were eight miles astern of him, and 30m. away on his starboard quarter was Beatty with five battle-cruisers. Keyes, in the "Lurcher," had stationed his submarines, but was still unaware of the presence of the cruisers, a fact which, as will be seen later, complicated the situation during the forenoon, when, owing to the mist, the course of events was by no means clear. Meanwhile, intercepted wireless signals had warned the Germans that a considerable force was approaching the Bight and they altered their normal dispositions. Their patrol force was ordered to retire before the British destroyers and to try and entice them into the Bight, where the light cruisers would be ready to cut them off. Thus, at daylight, the position was an interesting one, the destroyer forces being each intent upon leading its opponent into the arms of its supporting cruisers.

THE FIRST PHASES

The morning broke dull and overcast, with a smooth sea. To seaward the horizon was clear, but inshore it was misty, with the visibility never exceeding three to four miles and sometimes much less. At 4.45 A.M. E.7 fired a torpedo at one of the German outer patrol (G. 194), and this brought the German 5th flotilla out from Heligoland to hunt the submarine. At this time Tyrwhitt, in the "Arethusa," with the 3rd flotilla, was steering S.S.E. into the Bight, followed by "Fearless" with the 1st flotilla. Shortly before 7.0 A.M. a German t.b.d. was sighted on the port bow, about 3½m. off, and "Laurel," with the 4th division, was sent in chase (see fig. 1). The enemy turned S.E. and "Laurel" soon sighted ten more destroyers; shots were exchanged at long range as the Germans made off towards Heligoland. Tyrwhitt turned to the eastward to support his chasing division and, just before 8 A.M., the

"Stettin" came in sight to the N.E. Her arrival was opportune, for the German destroyer "V.1" had been hit and was dropping astern. A few minutes later "Frauenlob" was seen to the eastward and "Arethusa" for a short time came under a heavy fire from both German cruisers. "Stettin," which had not yet got steam for full speed, on sighting "Fearless" with her flotilla, turned away and disappeared into the mist. "Frauenlob" turned to the south-west-

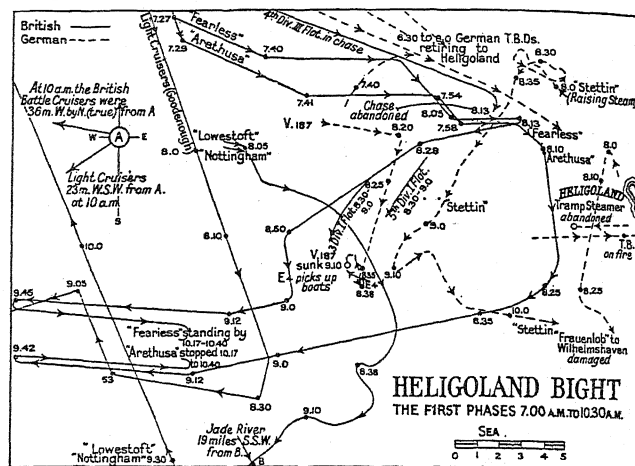

FIG. 1.—INITIAL MOVEMENTS IN BATTLE OF HELIGOLAND BIGHT, DURING WHICH ONE GERMAN CRUISER WAS DAMAGED, ONE DESTROYER SUNK AND H.M.S. "ARETHUSA" RECEIVED DAMAGE TO HER ENGINES

ward, and "Arethusa," turning to a converging course, a sharp fight ensued. "Arethusa," which had been commissioned only the day before, suffered heavily. She came under the fire of the forts of Heligoland and by 8.20 A.M. had only one 6in. gun remaining in action; but she continued her fight with "Frauenlob." At 8.25 A.M. the latter, heavily hit on her forebridge, broke off the action and retired. She reached Wilhelmshaven at noon with 50 killed and wounded on board. A tramp steamer, attempting to cross the bows of "Arethusa," was turned back by the British destroyers, who also chased and smashed up the torpedo boats D.8 and T. 33. After "Frauenlob" had retired S.E. Tyrwhitt turned W. He had, at 8.13 A.M., made the signal "Course W½S" (the course for the sweep), but delayed turning himself until he had finished with "Frauenlob." "Fearless," having lost sight of "Stettin," turned to the new course and recalled the chasing destroyers. The first phase thus closed at 8.30 A.M. with the British flotillas steering to the westward as planned, "Fearless" being about six m. to the north of "Arethusa."

THE SINKING OF "V.187"

The mist had now thickened, and soon after turning, "Fearless" sighted a destroyer coming in from seaward. At first she was mistaken for the "Lurcher," but soon identified as an enemy. "Goshawk" with the 5th and "Ferret" with the 3rd divisions were sent in chase. The enemy was "V.187," the leader of the German flotillas, and she attempted to escape to the southward. At 8.0 A.M. Goodenough had detached "Nottingham" and "Lowestoft" to Tyrwhitt's assistance and "V.187," sighting these two cruisers ahead at 8.38 A.M., was turned back by their 6in. guns into the arms of "Fearless" and eight destroyers. She was soon reduced to a wreck and she sank at 9.10 A.M. "Fearless," leaving the destroyers to deal with "V.187," rejoined Tyrwhitt and together they resumed the westerly course by 9.0 A.M.

The survivors of the sinking German were rescued by boats from the British destroyers. Whilst the rescue work was in progress "Stettin" appeared from the north and, opening fire upon the destroyers, scattered them, herself receiving a few hits whilst doing so. In the confusion, five boats, full of German wounded and prisoners, were left behind. Submarine "E.4" (Lt.-Com. Leir), made an unsuccessful attack upon "Stettin," which caused that ship to withdraw; then, appearing suddenly on the surface, she went to the rescue of the British boat's crews. One German officer and three men were kept as prisoners; the remainder were left in the British boats, were supplied with bread and water, and given the course to Heligoland. "E.4" then submerged as dramat-

ically as she had appeared.

Goodenough, with four cruisers, turned westward at 8.30 A.M., being at that time ten m. ahead of the flotillas. "Nottingham" and "Lowestoft," after heading off "V.187," tried to rejoin Goodenough, but failing to regain touch, they steered N.W. for the battle-cruiser position. Keyes in "Lurcher," still unaware of the presence of the northern force, sighted and shadowed them, under the impression they were enemy ships. Through the mist, just before 9.0 A.M., Keyes sighted Goodenough's four other ships astern. He informed "Invincible" that he was being chased by four cruisers and was trying to lead them towards her. Goodenough followed "Lurcher" for about ten minutes and then turned back to the westerly course. This took his ships over the outer line of British submarines, who were still unaware of his presence. At 9.30 A.M. "Southampton" sighted "E.6" and promptly attempted to ram; the submarine escaped only by making a rapid dive. Towards 10.0 A.M., the weather to seaward becoming clearer, mutual recognition took place between Keyes and Goodenough and the latter went on to the westward, in order to give the submarines freedom of action.

Tyrwhitt had intercepted Keyes's message to "Invincible," and at 9.45 A.M. he gallantly turned back to his assistance with the crippled "Arethusa." "Fearless" turned back at the same time, and by 10.0 A.M. the 3rd and 5th divisions, having rejoined after sinking "V.187," the re-united flotillas turned once more to the westward. But by this time "Arethusa" could only steam at ten knots, and at 10.17 she was forced to stop to repair her engines. "Fearless" stood by her, and by 10.45 A.M. the two ships were under way again, steaming slowly W., with the destroyers spread out ahead of them.

THE MAIN ACTION

The German command, in the Jade river, had by now realized the situation and was endeavouring to concentrate the light cruisers to attack the British flotillas (see fig. 2). "Mainz" left the Ems river at 9.0 A.M. and was coming up from S.W., hoping to cut off the destroyers and to join "Strassburg." That ship left the Jade river at 9.30 A.M., followed at intervals by "Cöln," "Ariadne," "Stralsund," and "Kolberg," while the "Stettin" was on her way W. from Heligoland. Thus six light cruisers were endeavouring to encompass the British flotillas, whose position

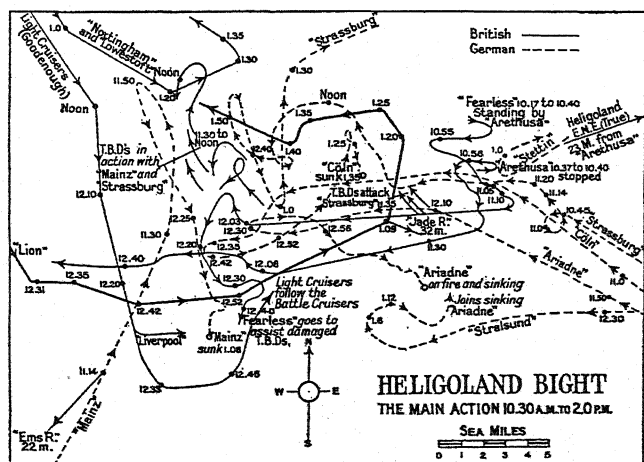

FIG. 2.—CHART SHOWING THE ATTEMPT OF GERMAN CRUISERS TO SURROUND BRITISH FLOTILLAS. THE MOVE WAS UNSUCCESSFUL. BRITISH BATTLE CRUISERS DASHING IN AND SINKING THREE GERMAN CRUISERS

from 11.0 A.M. onwards was precarious. Soon after "Arethusa" resumed her westerly course at 10.45 A.M. "Strassburg" appeared from S.E., and after firing a few salvos at long range disappeared in the mist to the northward. She was followed at 11.5 A.M. by "Cöln," which also passed on after exchanging a few salvos. When "Cöln" appeared Tyrwhitt asked Beatty for support. At 11.16 A.M. "Strassburg" reappeared to the northward and opened a heavy fire upon "Arethusa." A determined attack by the 1st and 2nd divisions of the 3rd and the 1st division of the 1st flotillas drove her off, and the stricken "Arethusa" continued her course

to W., supported by "Fearless" and the destroyers. When "Strassburg" reappeared "Fearless" sent out an urgent call for help, and Beatty, at 11.20 A.M., ordered Goodenough to turn back to the assistance of the flotillas.

To Beatty, who had been steaming at high speed around a position about 50m. to the N. and W. of Heligoland, the course of events had by no means been clear. The urgent call from "Fearless," however, made it evident that she and the "Arethusa" were in action with two or more cruisers. The flotillas were still within 30m. of Heligoland, and at any time after noon there was a possibility of heavy enemy ships appearing from the Jade river. Goodenough was turned back, and Beatty, accepting the risk of mines and submarines, determined to take his whole force into the Bight to clear matters up and to extricate "Arethusa" and the flotillas. By 11.30 A.M. the battle-cruisers were forming single line ahead on a S.E. course and were working up to full speed.

The Sinking of the "Mainz."—At 11.30 A.M. the 2nd, 3rd, and 5th divisions of the 1st flotilla were about six m. to the westward of "Arethusa" when the "Mainz" appeared right ahead and chased them away to the north. At 11.50, after a 20 min. chase, "Mainz" sighted Goodenough's four cruisers coming out of the haze from N.W. and the whole aspect of affairs was at once changed. "Mainz" turned S., followed by the destroyers she had been chasing, and was hit twice by the cruisers before she could draw away in the mist. At 12.08, she met "Fearless" with the remainder of the 3rd flotilla, and in the sharp fight that followed her rudder and port engine were damaged and she was hit by a torpedo from one of the destroyers. Goodenough's cruisers were now closing up and the fate of "Mainz" was sealed. She turned and dealt savagely with the 4th division when they attacked. "Laurel" had her after-funnel blown away and her captain severely wounded, "Laertes" was stopped dead by four hits from the same salvo, and "Liberty's" mast was shot away and her captain killed. But "Mainz," under the concentrated fire of the cruisers and destroyers, soon became a helpless wreck. She struck at 12.50, and 18 minutes later she rolled over and sank. Keyes, in the "Lurcher," went alongside and rescued 348 of her crew, narrowly escaping damage from her propellers as she sank.

The Battle-Cruisers in Action.—During the half-hour after noon the two British flotilla leaders were in grave danger of being overwhelmed. "Mainz" had appeared ahead, "Cöln" and "Ariadne" were fast coming up astern, followed by "Stralsund" and "Stettin," and "Strassburg" was in action with the destroyers about five m. to the N.E. Goodenough's arrival and the sinking of the "Mainz" relieved the pressure and Tyrwhitt continued to limp slowly to the westward. At 12.30 "Arethusa" sighted a large ship in the mist ahead, and after a moment of breathless suspense recognized her as the "Lion," followed by the battle-cruiser squadron. Steaming at high speed, Beatty left the "Arethusa" to port and the sinking "Mainz" to starboard and swept on. Goodenough's cruisers joined in astern and "Fearless" turned away to the assistance of "Laurel" and her damaged consorts. The German cruisers fled. "Strassburg" turned N., disappeared into the mist, and was no more seen. "Cöln," sighted on the port bow of the "Lion," made a desperate attempt to escape to N.E. but a few salvos disabled her engines. "Ariadne" tried to pass ahead of "Lion" on a S.E. course, but, hit by the first two salvos fired at her, she disappeared to the southward, badly on fire and sinking. "Stralsund" and "Stettin" turned eastward and escaped. At 1.09 P.M. Beatty, being only 32m. from the mouth of the Jade river, made the general signal to retire. The battle-cruisers turned in a wide circle to the N. and W. and at 1.25 P.M. the "Cöln" was seen again, steaming slowly to the S.E. Three salvos caused her to list to port and at 1.35 P.M. she sank, taking with her the German cruiser admiral and all her ship's company.

Thus, in a brief hour, Beatty's bold stroke with the battle-cruisers had turned an awkward situation into a brilliant success. The British force withdrew homewards and all ships arrived safely at their ports. Two only, the "Arethusa" and "Laurel," had to be towed home. The German battle-cruisers were slow in getting to sea and did not leave the Jade river until 2.0 P.M. By 4.0 P.M., accompanied by destroyers and the remnants of the light cruiser

squadron, they reached a position close to where the "Cöln" had sunk, and, seeing no enemy, returned to the shelter of their base.

The success achieved in this operation exceeded all expectations and its effects were far-reaching. It came at a time when the British nation needed a success to dispel the dismay caused by the overwhelming advance of the German armies. Upon the British navy the effect was exhilarating. The command of the North Sea had been asserted right up to the gates of the enemy and the young destroyer commanders had acquired a sense of superiority over their enemy and a trust in their leaders. Serious as was the material loss to the German fleet, it was not comparable to the effect upon its morale. Admiral Tirpitz stated that "August 28 was a day fateful, both in after effects and in incidental results, to the work of the German navy." Certainly, the marked disinclination shown by the German fleet throughout the war to be drawn from the protection of its bases is attributable to this early British success in the Bight of Heligoland.

(S. T. H. W.)

HELIOCENTRIC, *i.e.*, referred to the centre of the sun ($\eta\lambda\iota\omicron\varsigma$) as an origin, a term designating especially co-ordinates of heavenly bodies referred to that origin.

HELIODORUS, of Emesa in Syria, Greek writer of romance. He was the author of the *Aethiopica*, the oldest and best of the Greek romances that have come down to us. It was first brought to light in modern times in a ms. from the library of Matthias Corvinus, found at the sack of Buda (Ofen) in 1526, and printed at Basle in 1534. Other codices have since been discovered. The story is that the daughter of Persine, wife of Hydaspes, king of Aethiopia, was born white. Fearing an accusation of adultery, the mother gives the babe to the care of a gymnosophist. The child is finally taken to Delphi, and made a priestess of Apollo under the name of Charicleia. Theagenes, a noble Thessalian, comes to Delphi and the two fall in love with each other. He carries off the priestess with the help of an Egyptian, employed by Persine to seek for her daughter. After many adventures the chief personages meet at Meroë at the very moment when Charicleia is about to be sacrificed to the gods by her own father. Her birth is made known, and the lovers are married. The rapid succession of events, the variety of the characters, the graphic descriptions of manners and of natural scenery, the simplicity and elegance of the style, give the *Aethiopica* great charm. As a whole it offends less good taste and moral decency than other romances of its class. Homer and Euripides were the favourite authors of Heliodorus, who in his turn was imitated by French, Italian and Spanish writers. The early life of Clorinda in Tasso's *Jerusalem Delivered* (canto xii. 21 sqq.) is almost identical with that of Charicleia; Racine meditated a drama on the same subject; and it formed the model of the *Persiles y Sigismunda* of Cervantes. According to the ecclesiastical historian Socrates (*Hist. eccles.* v. 22), the author of the *Aethiopica* was a certain Heliodorus, bishop of Tricca in Thessaly. But it is now generally agreed that the real author was a sophist of the 3rd century A.D.

The best editions are: A. Coraës (1804), G. A. Hirschig (1856); see also M. Oeftering, *H. und seine Bedeutung für die Literatur*, with full bibliographies (1901); J. C. Dunlop, *History of Prose Fiction* (1888); and especially E. Rohde, *Der griechische Roman* (1900). There are translations in almost all European languages.

HELIOGABALUS (ELAGABALUS), Roman emperor (A.D. 218–222), was born at Emesa about 205. His real name was Varius Avitus. On the murder of Caracalla (217), Iulia Maesa, Varius's grandmother and Caracalla's aunt, left Rome and retired to Emesa, accompanied by her grandsons (Varius and Alexander Severus). Varius, though still only a boy, was appointed high priest of the Syrian sun-god Elagabalus, one of the chief seats of whose worship was Emesa (Homs). His beauty, and the splendid ceremonials at which he presided, made him a great favourite with the troops stationed in that part of Syria, and Maesa increased his popularity by spreading reports that he was in reality the illegitimate son of Caracalla. An insurrection was set on foot, and on May 16, 218 Varius was proclaimed emperor as Marcus Aurelius Antoninus. The troops sent to quell the revolt went over to him, and Macrinus was defeated near Antioch on June 8. Helioabalus was at once recognized by the senate as emperor.

After spending the winter in Nicomedia, he proceeded in 219 to Rome, where he made it his business to exalt the deity whose priest he was and whose name he assumed. The shameless profligacy of the emperor's life was such as to shock even a Roman public. His popularity with the army declined, and Maesa, perceiving that the soldiers were in favour of Alexander Severus, persuaded Helioabalus to raise his cousin to the dignity of Caesar (221), a step of which he soon repented. An attempt to murder Alexander was frustrated by Maesa. Another attempt in 222 produced a mutiny among the praetorians, in which Helioabalus and his mother Soemias (Soaemias) were slain (probably in the first half of March).

HELIOMETER, an instrument originally designed for measuring the variation of the sun's diameter at different seasons of the year (named from Gr. $\eta\lambda\iota\omicron\varsigma$, sun, and $\mu\epsilon\tau\rho\nu$, a measure). By subsequent improvements it became one of the most accurate astronomical instruments for measuring angular distances between stars, but its work is now done by photography and the heliometer is rarely used.

In the standard heliometer the object-glass is cut into two semi-circular segments. In the zero position the two halves form practically a single object-glass; they can be displaced by sliding their straight edges over one another, the amount of displacement being measured by a screw; a double image of each star is thus formed, *i.e.*, one by each half-lens. If the distance between two stars is being measured, the observation consists in turning the screw until the image from one star coincides with that from the other. For greater precision it is found desirable to move both segments an equal amount in opposite directions, so that the centre of the field of view where the observations of coincidence are made remains a centre of symmetry. Distances up to 2° are measured with these instruments.

The first use of a divided object-glass to give a double image is due to Servington Savary in 1743, but his segments were not movable. Pierre Bouguer (1748) invented an instrument used in the manner of a modern heliometer but employing two complete lenses instead of half-lenses to give the double image. In 1754 John Dollond combined Savary's idea of the divided object-glass with Bouguer's method and constructed the first really practical heliometer. The heliometer acquired a great reputation through the work of Bessel at Königsberg, who used it to measure the parallax of 61 Cygni. Many instruments were made for the transit of Venus expeditions in 1874. The last great heliometer observer was Sir David Gill; his measurements of the parallax of southern stars remained for a long while unsurpassed; he used it also for his important determinations of the solar parallax by observations of Mars and certain minor planets.

See Bessel, *Astronomische Untersuchungen*, vol. i.; Gill, *Annals of Cape Observatory*, vol. vii., pp. 1–71.

HELIOPOLIS, an ancient city of Egypt (the Biblical *On*). It stood 5 m. E. of the Nile at the apex of the Delta. It was the principal seat of sun-worship, and in historic times its importance was entirely religious. There appear to have been two forms of the sun-god at Heliopolis in the New Kingdom—namely, Ra-Harakht, or Rē-Harmakhis, falcon-headed, and Etōm, human-headed; the former was the sun in his mid-day strength, the latter the evening sun. A sacred bull was worshipped here under the name Mnevis (Egyp., *Mreu*), and was especially connected with Etōm. The sun-god Rē' (see EGYPT: *Religion*) was especially the royal god, the ancestor of all the Pharaohs, who therefore held the temple of Heliopolis in great honour. Each dynasty might give the first place to the god of its residence—Ptah of Memphis, Ammon of Thebes, Neith of Sais, Bubastis of Bubastis, but all alike honoured Rē'. His temple became in a special degree a

depository for royal records, and Herodotus states that the priests of Heliopolis were well informed in matters of history. The schools of philosophy and astronomy are said to have been frequented by Plato and other Greek philosophers; Strabo, however, found them deserted, and the town itself almost uninhabited, although priests were still there. The Ptolemies probably took little interest in their "father" Rē, and Alexandria had eclipsed the learning of Heliopolis; thus with the withdrawal of royal favour Heliopolis quickly dwindled.

In Roman times obelisks were taken from its temples to adorn Rome and the northern cities of the Delta. Finally the growth of Fostat and Cairo, only 6 m. to the S.W., caused the ruins to be ransacked for building materials. The site was known to the Arabs as *'Ayin esh shems*, "the fountain of the sun," more recently as Tel Hisn. It has now been brought for the most part under cultivation, but the ancient city walls are to be seen in the fields on all sides, and the position of the great temple is marked by an obelisk, and a few granite blocks bearing the name of Rameses II.

HELIOSTAT, an instrument containing a mirror driven by clockwork so as to reflect sunlight in a fixed direction; e.g., on to the slit of a fixed spectroscope. It is of more complicated design than the coelostat (*q.v.*). It has the advantage over the coelostat that the instrument fed by it need not be moved from day to day as the declination of the sun changes; the disadvantage is that only one point of the image remains fixed, the remainder rotating around it, so that unlike the coelostat it cannot be used for photographing an extended region.

HELIO THERAPY (*see* PUBLIC HEALTH; THERAPEUTICS). Heliotherapy, or treatment by sunlight, has been intermittently practised since the dawn of history, but its scientific use dates from the time of Finsen, who developed light treatment by employing artificial light, notably the carbon arc. It owes much to the work of Bernhard and Rollier, who commenced treatment with natural sunlight early in the present century. The latter has done much to popularize its use, especially in non-pulmonary tuberculosis.

Essential Conditions.—The most obvious benefits are seen in patients suitably exposed to solar rays. Certain essentials are necessary to obtain good results. The patient exposed to the sunlight should first be acclimatised; he must never be too hot nor too cold; in brilliant sunshine his head should be protected, and if there is much glare his eyes should be shielded by dark goggles. Exposure should be gradual: first the feet are sunned for short periods daily, the length of exposure and the area exposed being increased slowly, so that at the end of a fortnight exposure of the whole body may be generally tolerated with safety. Periods of exposure are gradually lengthened, until eventually the patients are often able to tolerate and benefit by exposure of the nude skin for from three to four hours daily.

There are great variations in the optimum exposure of different individuals. Generally speaking, brunettes tolerate exposure better than blondes; individuals who freckle but whose skins do not brown must be exposed with great caution, while albinos can barely tolerate exposure at all. On the normal skin an erythema develops within six hours of exposure; care should be taken not to exceed this erythema, and blistering is to be avoided. Gradually the skin becomes bronzed, and as this bronzing deepens so may exposure be prolonged, the pigment protecting the patient from the harmful effects of the actinic rays.

Insolation necessarily involves exposure of the body to the cold air, and the latter has been shown to increase the metabolic activity of the subject treated. The rays of greatest therapeutic value are the ultra-violet or actinic rays, the light waves of shortest wave-length in the solar spectrum. These are most intense at the seaside or on the mountains. Excess of heat rays is to be avoided, and insolation for its therapeutic value is thus better carried out in temperate than in tropic regions. Properly timed exposure on the individual responding to treatment is associated with a tonic and exhilarating effect; exposure unduly prolonged results in fatigue and exhaustion.

Effects of Insolation.—While properly applied insolation exer-

cises a tonic effect on the body, it is equally stimulating to the mind. The exposed subject is more cheerful and exhilarated, mental responses are brisker and mental activities more pronounced. On the body the effect of insolation may be described as local or direct and remote or indirect. Light exercises a beneficial effect on superficial lesions by reason of the direct bactericidal action of the actinic rays, assisted by the favourable inflammatory response which carefully timed exposure elicits.

The remote beneficial effects are more marked but less easy to explain. Eidenow has shown that the haemobactericidal power is often raised after an erythema dose. This enhanced power of the blood to destroy pathogenic organisms is obtainable equally when a portion or the whole of the skin is exposed, and, if increased haemobactericidal power is alone sought, fractional exposures of different portions of the skin at consecutive sessions is the method of treatment of choice. Sonne has demonstrated that the visible rays of the solar spectrum have great penetrative power, pass through the skin, and are absorbed in the subjacent blood, their physical being transformed into thermal energy. He has suggested that this local heating effect is of value in destroying deleterious circulating toxins. Investigations have shown that the calcium, phosphorus and iron content of the blood may be raised by insolation.

Sunlight treatment has its greatest therapeutic value in increasing and maintaining bodily tone and energy, in the treatment of the various manifestations of surgical tuberculosis, in the treatment of rickets and the relief of nervous asthma. It is of proved value in certain affections of the skin, notably psoriasis. It is of great assistance in a variety of conditions, accelerating and consolidating the cure, particularly in convalescence from debilitating diseases such as infectious fevers. Its stimulating effect is seen in increasing fecundity and in the treatment of certain defects of the endocrine glands. The range of its usefulness is being rapidly extended, in the main, as an aid to cure rather than as a specific treatment.

See A. Rollier and others, *Heliotherapy* (1923).

(H. J. G.)

FLOWERING BRANCH OF HELIOTROPE (*HELIOTROPIMUM SUAVEOLENS*), A SPECIES FOUND CHIEFLY IN RUSSIA AND EASTERN EUROPE

HELIOTROPE or TURNSOLE, *Heliotropium*, i.e., a plant which follows the sun with its flowers or leaves, a genus of usually more or less hairy herbs or undershrubs of the family Boraginaceae, having alternate, rarely almost opposite leaves; small white, lilac or blue flowers, in terminal or lateral one-sided simple or once or twice forked spikes, with a calyx of five deeply divided segments, a salver-shaped, 5-lobed corolla, and entire 4-celled ovary; fruit 2- to 4-sulcate or lobed, at length separable into four 1-seeded nutlets

or into two hard 2-celled carpels. The genus contains 220 species indigenous in the temperate and warmer parts of both hemispheres. A few species are natives of Europe, as *H. europaeum*, which is also a naturalized species in the southern parts of North America.

The common heliotrope of hot-houses, *H. peruvianum*, popularly known as "cherry-pie," is on account of the delicious odour of its flowers a great favourite with florists. It was introduced into Europe by the younger Jussieu, who sent seed of it from Peru to the royal garden at Paris. About the year 1757 it was grown in England by Philip Miller from seed obtained from St. Germain. *H. corymbosum* (also a native of Peru), which was grown in Hammersmith nurseries as early as 1812, has larger but less fragrant flowers than *H. peruvianum*. The species commonly grown in Russian gardens is *H. suaveolens*, which has white, highly fragrant flowers. What, from the perfume of its flowers, is sometimes called winter heliotrope, is the fragrant butterbur, or sweet-scented coltsfoot, *Petasites fragrans*, a perennial plant of the family Compositae.

In Mineralogy.—Heliotrope is the mineral commonly called "bloodstone" (*q.v.*), and sometimes termed girasol—a name applied also to fire-opal. The name, like those of many ancient names of minerals, seems to have had a fanciful origin. According to Pliny the stone was so called because when thrown into the water it turned the sun's light falling upon it into a reflection like that of blood.

HELIOZOA. Single-celled animals, mostly spherical in form, distinguished by numerous, somewhat stiff, protoplasmic processes (*axopodia*), which serve as organs of locomotion, and also are of use in the taking-in of food. See PROTOZOA.

HELIUM is a colourless, odourless gas of a family of elements, which on account of their extreme chemical inertness are termed the "inert" or "noble" gases. It is the lightest gas known except hydrogen. It was discovered in the sun (1868) many years before it was found on the earth. The spectroscope was used for the first time to examine the chromosphere round the sun during an eclipse, and it was observed that there was a brilliant yellow line, which the French astronomer J. Janssen showed was not coincident with the already well-known D₁ and D₂ lines of sodium. J. N. Lockyer and E. Frankland shortly afterwards concluded that this yellow line (known as D₃) was due to an unknown element which they called helium (Greek, *ἥλιος*, sun), symbol He, atomic number 2, atomic weight 4. Terrestrial helium was discovered by Sir W. Ramsay during the year 1894 while engaged in experiments on the sources of argon. He found that the inert gas obtained in considerable volume by heating the mineral cleveite, and hitherto thought to be nitrogen, was only partially removed by sparking with oxygen in the presence of caustic soda. The residual gas on spectroscopic examination showed a brilliant yellow line which W. Crookes definitely proved to be identical with the line observed by Janssen. H. Kayser (1895), whose work was later confirmed by S. Friedländer, first discovered the presence of helium in the atmosphere by spectroscopic means. The actual separation of helium from the atmosphere was effected by W. Ramsay and M. W. Travers, who obtained, by a method of fractional distillation, not only helium, but three new elements belonging to the same family of inert gases, namely neon, krypton and xenon. In the years that followed the discovery of helium, extensive work was carried out on its occurrences, properties and physical constants. W. Ramsay (1903) demonstrated that helium was a product of the radioactive disintegration of radium. This experiment stands out as being the first example of a transmutation of elements. The history of the production of helium on a commercial scale began when a German Zeppelin which had been pierced by incendiary bullets did not take fire (1914). Sir R. Threlfall suggested to the British Admiralty that the Germans had possibly discovered a new source of helium and had utilized this non-inflammable gas for filling the Zeppelin. The various possible sources of helium in the British empire were then reviewed. The natural gas supplies of Canada appeared to be the only source likely to yield helium in sufficient quantity for war purposes. A survey of the gas fields was instituted by J. C. McLennan of Toronto, and experi-

mental plants for the extraction of helium were set up at Hamilton in Ontario and Calgary in Alberta (1918). At the conclusion of the work (1920), about 60,000 cu. ft. of helium of 60 to 90% purity had been extracted. The work of H. P. Cady and D. F. Macfarlane (1907) on the helium-bearing gases of Kansas had already shown that the United States were in possession of supplies of helium which might be developed on a commercial scale, but nothing further was done until America entered the war (1917). Operations were then prosecuted with such vigour that at the time of the Armistice 147,000 cu. ft. of helium of 93% purity were on the dock ready for despatch to Europe for aeronautical purposes. A large scale plant was built at Fort Worth (1925), capable of turning out 1,000,000 cu. ft. per month, and this gas was proved by the aeronautical experts to be most eminently suitable for the filling of airships and balloons, provided it could be obtained in sufficient quantities at a reasonable price.

Occurrence.—Helium occurs, not only in the atmosphere of the sun, but also in certain of the fixed stars and many nebulae. It is a constituent of the earth's atmosphere and is found in most of the older rocks and minerals, in gases evolved from mineral springs, in natural gas, and in sea and river water in minute quantities. It has also been detected in certain fumarole and volcanic gases. W. Ramsay, using Dewar's method, estimated the amount in the atmosphere as one part in 250,000 by volume. W. Watson, later, by analysis of the gas separated from air by G. Claude's method, gave the value as one part in 185,000, which is probably a more exact figure. J. H. Jeans, on theoretical grounds, calculates, that at considerable altitudes, the proportion of helium in the atmosphere is materially increased, and that at a height of 5000. the atmosphere is made up of helium and hydrogen. J. Stoney states that a planet of the earth's dimensions cannot permanently retain the helium in its atmosphere and that the helium together with the hydrogen is continually lost into space. The minerals which contain helium are widely distributed throughout the earth's crust, but with few exceptions it is only in those containing the radioactive elements, thorium and uranium, that it is found in measurable quantity. The most important helium minerals are cleveite, monazite, fergusonite, bröggerite, samarskite, thorianite and euxenite. Helium is found in the gases evolved from mineral springs. The French springs which have been systematically examined by C. Moureu and A. Lepape evolve considerable amounts of helium. The Mazières spring gives a gas containing 6% of helium, whilst that at Santenay gives over 9%. This spring alone is calculated to give more than 6000 cu. ft. of helium per year. The only mineral spring in England containing helium is the one at Bath, estimated by R. T. Elworthy (1918) to contain 0.21%. The natural gases of America are now recognized as the chief source of helium, as already mentioned. R. D. Moore estimates that more than 1,000,000 cu. ft. of helium run to waste in natural gas every 24 hours. The gas fields of Ontario and Alberta contain 0.33 to 0.34% helium, but the total Canadian supply is small compared with that of the United States.

Isolation and Purification.—Helium may be prepared from any of the sources mentioned above. The preparation from the minerals is effected by heating them either alone or with sulphuric acid. Thorianite, which consists mainly of thorium oxide, is one of the most convenient minerals for the preparation of helium, since 1 gram yields as much as 9.5 c.c. of the gas. Monazite, which is largely used in the incandescent mantle industry, contains less helium than thorianite but is more abundant. One gram of the mineral yields 1 c.c. of helium. The monazite is heated with strong sulphuric acid, and the evolution of gas is complete within two hours. The gas, so obtained, after washing with caustic soda solution, contains about 90% helium. The isolation of helium from natural gas is most easily effected on a small scale by Dewar's method. The gases are passed over charcoal, cooled to the temperature of liquid air, and under these conditions only the helium escapes absorption. All gases, other than neon and hydrogen, may be completely separated from helium by Dewar's charcoal method. In order to separate neon from helium, the gas must be cooled to the temperature of liquid hydrogen, when the neon condenses. Hydrogen is usually removed by chemical means. Oxygen is

added, and the mixture is exploded by an electric spark, with the result that the hydrogen is converted into water. Alternatively, the gas is passed over copper oxide, when also conversion of the hydrogen to water takes place.

Properties.—Helium possesses several remarkable properties of special interest to the scientist. Its atom has a relatively simple structure, and it has been possible to draw many theoretical conclusions from its behaviour. The density (0.1368, air = 1) is less than that of any other known gas except hydrogen (0.0696). The molecular weight of helium calculated from its density is approximately 4. Helium is a monatomic gas. The calculated ratio of the two specific heats (those at constant pressure and at constant volume) of a monatomic gas is 1.667. W. Ramsay found the ratio for helium to be 1.652, and K. Scheel and W. Heuse found it to be 1.66 at 18° and 1.673 at 180°. Additional evidence that helium is monatomic is derived from a consideration of other physical properties, such as dielectric constant, thermal conductivity and Zeeman effect; also from its position in the periodic classification of the elements. The rate of diffusion of helium through a porous tube is less than the value calculated from Graham's law of diffusion of gases. F. G. Donnan has suggested that this is due to the rise in temperature which is known to occur on free expansion of the gas through a small orifice. The permeability of various fabrics to helium has been investigated on account of its use in airships and balloons. Rubbed fabrics are found to be only about 0.7 times as permeable to helium as to hydrogen. In the case of skinned fabrics, however, the ratio is nearly unity. Quartz glass is easily permeable to helium at red heat, and it has recently been discovered that it is also permeable at ordinary temperatures to helium at a pressure of 100 atm. Helium is less soluble in water than any other known gas: the solubility at 10° is a minimum, 0.0100. The coefficient of increase of pressure with rise of temperature at constant volume is perfectly normal. The value found by W. Ramsay for this coefficient between 0° and 100° is 0.0036616, and H. K. Onnes observed that this value is independent of the original pressure. The constancy of the pressure coefficient of helium has led to its application to thermometry where it is of especial value in the measurement of low temperatures. The thermal conductivity of helium has a comparatively high value, approaching that of hydrogen. The Shakespeare catharometer, whose operation depends on this physical property, has been applied to the analysis of helium produced on a commercial scale where nitrogen usually is the only impurity. The spectrum of helium was studied by C. Runge and F. Paschen, who found that it contained six series of lines which fall into two groups, each group consisting of a special series and two secondary series. The first group is a series of doublets of which the D_3 doublet is the principal. The second group is a single-line series, the most important of which is the green line 5015. The colour of the light emitted by a Plücker tube filled with helium under the influence of an electric discharge depends on the pressure of the gas: at 7–8 mm. the colour of the glow is a brilliant yellow, since the D_3 (5876) line then reaches its maximum intensity. If the pressure is gradually reduced the intensity of the green line (5015.6) increases, till at 1 to 2 mm. the tube emits a brilliant green light. The presence of impurities in helium causes a marked change in the appearance of the spectrum and may completely mask the helium lines; this masking effect is considerably reduced at low pressures. Helium was liquefied by H. K. Onnes (1908) who used a specially constructed liquefier of the Hampson type. It was necessary to pre-cool the helium to a temperature of -258°C with liquid hydrogen boiling under reduced pressure, since at ordinary temperatures heating is produced by the expansion of helium through a nozzle. Onnes obtained 60c.c. of liquid from 300 litres of gas, and determined its physical constants. It is a colourless mobile liquid boiling at 4.25°A . The critical temperature is 5.25°A ., the critical pressure 2.26 atm., and the critical density 0.066. Liquid helium has proved an invaluable agent for the attainment of extreme cold. By its evaporation under reduced pressure it is possible to reach a temperature slightly lower than 0.9°A . Helium was solidified by W. H. Keesom (1926). When a tube system containing liquid helium

became blocked he assumed that the helium had solidified. The following solidification points were determined: 1.1°A ., 2.6°A ., 2.2°A ., 50 atm.; 3.2°A ., 86 atm.; 4.2°A ., 150 atm. Helium, as is also common with the other rare gases, is characterized by its extreme chemical inactivity. All the attempts of W. Ramsay and J. N. Collie to make helium combine with a second element ended in failure. Helium was circulated over various elements and substances at a bright red heat, but in no case was there any evidence of a reaction. Berthelot (1895) subjected helium to the action of a silent electric discharge in the presence of benzene and mercury. A large proportion of the gas was absorbed and a resinous solid produced. A green glow was also seen which gave the spectrum of mercury. J. J. Manley (1926) obtained evidence of the formation of a gaseous mercury helide formed from helium and mercury under the influence of an electric glow discharge. Boomer subjected helium, in conjunction with mercury, iodine, sulphur and phosphorus, to electronic bombardment in the presence of a surface cooled with liquid air, and obtained evidence of the formation of compounds of helium with the elements mentioned.

Radioactivity.—Whenever helium occurs in nature it appears, with few exceptions, to be associated with the phenomenon of radioactivity, and it is generally believed that helium in nature has arisen from the various radioactive elements. The best known of these elements, radium, thorium and uranium, are characterized by the emission of radiations which can be detected by the electrical or photographic effects produced by them. These radiations have been divided into three classes, namely, alpha-, beta-, and gamma-rays (briefly, α -, β -, and γ -). E. Rutherford (1907) was the first to suggest that the α -rays consisted of a stream of helium atoms carrying two unit positive charges. W. Ramsay and F. Soddy demonstrated the truth of this theory by a spectroscopic study of the emanation from a solution of radium bromide. The emanation gradually developed a helium spectrum, as shown by the characteristic D_3 line. Later E. Rutherford and T. Roydes conclusively showed the identity of the α -particle with helium. The emanation from radium was stored in exceedingly thin-walled glass tubes surrounded by an outer exhausted jacket. The tubes were impervious to ordinary gaseous helium but allowed nearly all the α -particles to escape into the outer jacket. The gas which collected there was passed into a tiny spectrum tube and shown to be helium. The radioactive elements are distributed with great uniformity in the rocks which constitute the earth's surface. Though the amount in most rocks is small, the sum total is sufficient to account for the helium that exists in nature.

Commercial Production.—Helium is separated from natural gas on a commercial scale by liquefaction methods, similar to those employed in the separation of oxygen from the atmosphere. A typical analysis of natural gas from the Petrolia field in the United States is as follows: helium 0.93%; carbon dioxide 0.25%; oxygen 0.54%; methane 56.85%; ethane and heavier hydrocarbons 10.30%; nitrogen 31.13%. In the large-scale extraction plant at Fort Worth, carbon dioxide is removed from the gas by washing with lime water; the gas is then compressed and cooled, first by a carbon dioxide cycle in a fore-cooler, and next in heat interchangers, when it meets the cold gases returning from the still. The gas is then expanded through a nozzle, and enters the bottom of the still, partly as a liquid and partly as a gas. The still consists of three units, each of which has a rectifying column with a condenser at the top and a receiver at the bottom. The liquids which collect in the upper receivers are used to cool the condensers underneath. The top condenser is cooled by a nitrogen cycle. The heavier hydrocarbons condense in the lowest unit, while methane and most of the nitrogen are liquefied in the top unit. Helium mixed with a little nitrogen, escapes from the top of the still and is passed to storage. The cold gases, obtained by the evaporation of the liquefied hydrocarbons and nitrogen, pass out through the heat interchangers. The natural gas thus stripped of its helium is returned to gas mains for subsequent industrial or domestic use. The plant at Fort Worth consists of six complete units each designed to handle approximately 44,000 cu.ft. of natural gas per hour, and extracts on the average 60% of the helium of the gas.

Helium up to 95% purity may be obtained by this process, at a cost of about \$24 per 1,000 cu. ft. The patents for this process are owned by the Linde Air Products Co., which also designed and still operates the plant for the United States Government.

Technical Applications.—Various tests made in the United States have shown that helium is the ideal gas for filling airships and balloons, and its use has necessitated new methods in the operation of airships. The German practice has been to waste large amounts by valving, so that as much gas as 20 times the volume of the airship was used each year. In order to prevent wastage of helium by valving, the loss in weight due to consumption of fuel has been compensated by condensation of water from the exhaust gases of the engines. Also, when possible, the airship is driven down by means of her motors instead of by valving. Helium which has become too impure for flying purposes, through diffusion of air into the gas bag, is repurified either by cooling the compressed gas with liquid air, or by Dewar's charcoal method. Owing to the low solubility of helium in the fluids of the body, experiments have been made on the use of helium-oxygen mixtures in deep diving (*q.v.*) and caisson operations, as it is evident that the use of such mixtures in place of air will allow divers to work at greater depths or for longer periods. Many other technical applications of helium have been suggested, but the relatively small amount available for industrial use and the restriction on its export from the United States have hindered developments.

HELIX, a line which rises as it twists, such as the line of a screw thread. In architecture, the term helix is sometimes given to the spirally twisted stalks or volutes under the corners of the

LEFT, MINELLI COURT, VENICE, SHOWING HELIX FORM IN THE SPIRAL STAIRWAY; RIGHT, HELIX FORM OF A COLUMN, ST. PETERS, ROME

abacus of the Corinthian capital (*see ORDER*). The helix form is also found most commonly in architecture in those curving stairways which are popularly known as spiral.

HELL, used in English both of the place of departed spirits and of the place of torment of the wicked after death (O. Eng. *hel*, a Teutonic word from a root meaning "to cover"). In the O.T. it translates the Hebrew *Sheol*, in the N.T. the Greek *ᾗδης*, Hades, and *γέεννα*, Hebrew *Gehenna* (*see ESCHATOLOGY*).

HELLANICUS OF LESBOS, Greek logographer, flourished during the latter half of the 5th century B.C. According to Suidas,

he lived for some time at the court of one of the kings of Macedon, and died at Perperene, a town on the gulf of Adramyttium opposite Lesbos. Some thirty works are attributed to him—chronological, historical and episodic. Mention may be made of: *The Priestesses of Hera at Argos*, a chronological compilation; the *Karneonikai*, a list of the victors in the Carnean games (the chief Spartan musical festival), including notices of literary events; *Phoronis*, chiefly genealogical, dealing with the period up till the return of the Heracleidae; *Deukalionia*; his local histories include an *Attis*, giving the history of Attica from 683 to the end of the Peloponnesian War (404), in which Thucydides (i. 97), says the events of the years 480-431 were treated briefly and superficially, and with little regard to chronology; *Troika*, *Persika*, *Lesbiaka*, and others.

Hellanicus marks a real step in the development of historiography. He was not content to repeat the traditions that had gained general acceptance through the poets, but tried to give them as they were locally current, and by using the few national or priestly registers that presented something like contemporary registration, to lay the foundations of a scientific chronology, based primarily on the list of the Argive priestesses of Hera, and secondarily on genealogies, lists of magistrates (*e.g.* the archons at Athens), and Oriental dates, in place of the old reckoning by generations. But his materials were insufficient and he often had recourse to the older methods. On account of his deviations from common tradition, Hellanicus is called an untrustworthy writer by the ancients themselves. He appears to have made no systematic use of inscriptions, and he never, like his contemporary Herodotus, rose to the conception of a single current of events wider than the local distinction of race. His style, so far as it can be judged from the fragments, was bald.

Fragments in Müller, *Fragmenta historicorum Graecorum*, i. and iv.; and in F. Jacoby, *Fragmenta der Griechischen Historiker* (1923), where references in ancient authors are also quoted. *See* among older works L. Preller, *De Hellenico Lesbio historico* (1840); Mure, *History of Greek Literature*, iv.; late criticism in H. Kullmer, "Hellenikos" in *Jahrbücher für klass. Philologie* (Supplementband, xxvii. 455 sqq.) (1902) which contains new edition and arrangements of fragments; C. F. Lehmann-Haupt, "Hellenikos, Herodot, Thukydides," in *Klio* vi. 127 sqq. (1906); J. B. Bury, *Ancient Greek Historians* (1909), pp. 27 sqq.; the exhaustive article by Gudeman in Pauly-Wissowa viii. I.

HELL-BENDER, the American vernacular name for an aquatic salamander, *Cryptobranchus* (*q.v.*) *alleghaniensis*.

HELLEBORE, a genus (*Helleborus*) of plants of the family Ranunculaceae, natives of Europe and western Asia. They are coarse perennial herbs with palmately or pedately lobed leaves. The flowers have five persistent petaloid sepals, within the circle of which are placed the minute honey-containing tubular petals of the form of a horn with an irregular opening. The stamens are very numerous, and are spirally arranged; and the carpels are variable in number, sessile or stipitate and slightly united at the base and dehisce by ventral suture.

Helleborus niger, black hellebore, or, as from blooming in mid-winter it is termed the Christmas rose, is found in southern and central Europe, and with other species was cultivated in the time of Gerard (*see Herball*, p. 977, ed. Johnson, 1633), in English gardens. Its knotty root-stock is blackish-brown externally, and, as with other species, gives origin to numerous straight roots. The leaves spring from the top of the root-stock, and are smooth, distinctly pedate, dark-green above, and lighter below, with 7 to 9 segments and long petioles. The scapes, which end the branches of the rhizome, have a loose entire bract at the base, and terminate in a single flower, with two bracts, from the axis of one of which a second flower may be developed. The flowers have 5 white or pale-rose, eventually greenish sepals, 15 to 18 lines in breadth; 8 to 13 tubular green petals containing honey; and 5 to 10 free carpels. There are several forms, the best being *maximus*. The Christmas rose is extensively grown in many market gardens to provide white flowers about Christmas time for decorations.

H. orientalis, the Lenten rose, has given rise to several fine hybrids with *H. niger*, some of the best forms being clear in colour and distinctly spotted. *H. foetidus*, stinking hellebore, is a native of England, where like *H. viridis*, it is confined chiefly

to limestone districts; it is common in France and the south of Europe. Its leaves have 7- to 11-toothed divisions, and the flowers are in panicles, numerous, cup-shaped and drooping, with many bracts, and green sepals tinged with purple, alternating with the five petals.

H. viridis, or green hellebore proper, is probably indigenous in some of the southern and eastern counties of England, and occurs also in central and southern Europe. It has bright yellowish-green flowers, 2 to 4 on a stem, with large leaf-like bracts. O. Brunfels and H. Bock (16th century) regarded the plant as the black hellebore of the Greeks.

H. lividus, holly-leaved hellebore, found in the Balearic Islands, and in Corsica and Sardinia, is remarkable for the handsomeness of its foliage. White hellebore is *Veratrum album* (see VERATRUM), a liliaceous plant.

The rhizome of *H. niger* occurs in commerce in irregular and nodular pieces, from about 1 to 3 in. in length, white and of a horny texture within. Cut transversely it presents internally a circle of 8 to 12 cuneiform ligneous bundles, surrounded by a thick bark. It emits a faint odour when cut or broken, and has a bitter and slightly acrid taste. The drug is sometimes adulterated with the rhizome of baneberry, *Actaea spicata*, which, however, may be recognized by the distinctly cruciate appearance of the central portion of the attached roots when cut across, and by its decoction giving the chemical reactions for tannin. The rhizome is darker in colour in proportion to its degree of dryness, age and richness in oil.

H. niger, *orientalis*, *viridis*, *foetidus*, and several other species of hellebore contain the glucosides *helleborin*, $C_{38}H_{42}O_8$, and *helleborein*, $C_{26}H_{44}O_{13}$, the former yielding glucose and *helleboresin*, $C_{30}H_{38}O_4$, and the latter glucose and a violet-coloured substance *helleboretin*, $C_{14}H_{20}O_3$. Helleborin is most abundant in *H. viridis*. A third and volatile principle is probably present in *H. foetidus*. Both helleborin and helleborein act poisonously on animals.

HELLENISM. The term "Hellenism" is ambiguous. It is derived from Gr. ἑλληνίζειν, to speak the language of the Greeks, who called themselves Ἕλληνες, after Hellēn, the son of Deucalion. In late Greek Ἑλληνισμός means imitation of the Greeks (Septuagint, 2 Macc. iv. 13). It may be used to denote ancient Greek culture in all its phases. The German historian J. G. Droysen introduced the fashion of using it to describe particularly the latter phases of Greek culture from the conquests of Alexander to the end of the ancient world, when those over whom this culture extended were largely not Greek in blood; i.e., *Hellenes*, but peoples who had adopted the Greek speech and way of life, *Hellenistai*. While using the term in the larger sense, this article will devote its principal attention to Hellenism as it appeared in the world after spread of Greek culture which followed the Macedonian conquests.

I. THE EXPANSION OF HELLENISM BEFORE ALEXANDER

In the 5th century B.C. Greek cities dotted the coasts of the Mediterranean and the Black sea from Spain to Egypt and the Caucasus, and already Greek culture was beginning to pass beyond the limits of the Greek race. As early as the 7th century B.C., when Hellenism was still in a rudimentary stage, Greek mercenaries came to be in request throughout the Nearer East. But as Hellenism developed, its social and intellectual life began to exercise a power of attraction. The proud old civilizations of the Euphrates and the Nile might ignore it, but the ruder barbarian peoples came in various degrees under its spell. In some

cases an outlying colony would coalesce with a native population, and a fusion of Hellenism with barbarian customs take place.

The great developments of the century and a half before Alexander set the Greek people in a very different light before the world. In the sphere of material power the repulse of Xerxes greatly enhanced Greek military prestige. The kings of the East learnt more than ever upon Greek mercenaries, whose superiority to barbarian levies was further brought home to them by the expedition of Cyrus. But the developments within the Hellenic sphere itself were also of great consequence for its expansion outwards. The political disunion of the Greeks was to some extent neutralized by the rise of Athens to a leading position in art, literature and philosophy, and by the fact that the Attic dialect attained a classical authority; if Hellenism was to be propagated in the world at large, it was obviously convenient that it should have some one definite form of speech to be its medium.

1. **The Persians.**—The ruling race of the East, the Persian, was but little open to the new culture. The military qualities of the Greeks were appreciated, and so, too, was Greek science, where it touched the immediately useful; a Greek architect bridged the Bosphorus for King Darius; Greek physicians were retained at the Persian court. Exactly how far Greek influence can be traced in the remains of Persian art, such as the palaces of Persepolis and Susa may be doubtful, but it is certain that the engraved gems for which there was a demand in the Persian empire were largely the work of Greek artists.

2. **The Phoenicians.**—As early as the first half of the 4th century we find communities of Phoenician traders established in the Peiræus. In Cyprus, on the frontier between the Greek and Semitic worlds, a struggle for ascendancy went on. The Phœnician element seems to have been dominant in the island, when Evagoras made himself king of Salamis in 412, and restored Hellenism with a strong hand. Even into the original seats of the Phœnicians Hellenism began to intrude. Abdashtart, king of Sidon (374-362 B.C.), called Straton by the Greeks, entered into close relations with the Greek states, and imitated the Hellenic princes of Cyprus.

3. **The Carians and Lycians.**—The seats of the Greeks in the East touched peoples more or less nearly related to the Hellenic stock, with native traditions not so far remote from those of the Greeks in a more primitive age, the Carians and the Lycians. The Carian princes of the 4th century B.C., Hecatomnus and especially Mausolus, modelled themselves upon the pattern of the Greek tyrant. The capital of Mausolus was a Greek city, Halicarnassus, and all that we can still trace of his great works of construction shows conformity to the pure Hellenic type. His famous sepulchre, the Mausoleum (the remains of it are now in the British Museum), was a monument upon which eminent Greek sculptors worked in rivalry. In Lycia Greek influence is more limited. Here the native language maintains itself against Greek. The proper names are (if not native) mainly Persian. But the Greek language makes an occasional appearance; the coins are Greek in type; above all, the monumental remains of Lycia show strong Greek influence, especially the well-known "Nereid Monument" in the British Museum, whose date is held to go back to the 5th century.

4. **South Russia and the Danube Lands.**—A brisk trade, which reached its highest point of development in the 4th century B.C., sprang up between the Scythian chieftains and the Greek colonists. The finds of Greek pottery, and still more of gold and silver ware, in the tombs of southern Russia, have been very considerable. But in Scythia Greek influence appears to have been limited to the material sphere (see SCYTHIA). A similar trade connection, which also flourished most in the 4th century, sprang up between Greek merchants from the Black sea or the Adriatic and the inhabitants of the Danube lands. But in these regions the Greeks did less than the Celts and the Italians to introduce a higher civilization.

5. **Egypt.**—From the time of Psammetichus (d. 610 B.C.) Greek mercenaries had been used to prop Pharaoh's throne, and Greek merchants had begun to find their way up the Nile and even to the oases. A Greek city, Naucratis (q.v.), was allowed

BLACK HELLEBORE (HELLEBORUS NIGER), SHOWING GENERAL HABIT OF GROWTH. AT LEFT IS VERTICAL SECTION THROUGH THE FLOWER

to arise at the Bolbitinic mouth of the Nile. But the racial repugnance to the Greek probably kept the soul of the people more shut against Hellenic influences than was that of the other orientals.

6. **Macedonia.**—In Macedonia the native chiefs had been attracted by Hellenic life, at any rate from the beginning of the 5th century, when Alexander I. persuaded the judges at Olympia that his house was of good Argive descent (Herodotus, v. 22). It was probably not until the reorganization of the kingdom by Archelaus (413–399) that Greek culture found any abundant entrance into Macedonia. Archelaus' palace was decorated by Zeuxis; Euripides spent there the end of his days. From that time a certain degree of literary culture was general among the Macedonian nobility; their names in the days of Philip are largely Greek; the Macedonian service was full of men from the Greek cities within Philip's dominions, and Philip chose Aristotle to be the educator of his son. How far the country generally might be regarded as Hellenized is a problem which involves the vexed question whether Macedonian is to be considered a dialect of Greek.

7. **The West.**—The process of Hellenization was carried out most completely in Sicily, where the distinction between native Sicels and Greek settlers faded out in the 4th century B.C.

In Italy the peoples of the south, who came into direct contact with the Greek colonists, showed some proficiency in their imitations of Greek ceramic art and coinage, and they derived their alphabets, directly or indirectly, from Greek script. In Central Italy the Romans at first remained comparatively impervious to Greek influence, but the Etruscans in the 6th and 5th centuries became partially Hellenized. It is a moot point how far their alphabet was copied from Greek models, but the dependence of their art (architecture, sculpture, pottery, coins) is unmistakable.

In Gaul the native culture was little affected by Greek civilization until the end of the 4th century B.C. But by 300 B.C. the Greek colony of Massilia had become an important focus of Hellenism. The Druids of Gaul adopted the Greek alphabet and scraps of Greek philosophic lore. Imitations of Greek coins (especially the pieces of Philip II. of Macedon) were struck even in the remote parts of the country, and rude copies of the Gallic pieces were in turn produced in Southern Britain.

In Spain the native art of the eastern districts came under Greek influence in the 5th and 4th centuries B.C., but the growing political ascendancy of Carthage in the peninsula proved unfavourable to the spread of this influence.

In North Africa the Carthaginians, albeit political enemies of the Greeks, did not remain untouched by Greek culture. By the 4th century they had begun to copy Greek architecture, sculpture and coinage, and to use Greek as a subsidiary tongue.

II. AFTER ALEXANDER THE GREAT

By 350 B.C. Hellenism had not seriously affected any but the more primitive races which dwelt upon the borders of the Hellenic lands, and here, with the doubtful exception of the Macedonians, was rather for the courts than for the people. Everything was changed when by the conquests of Alexander (334–323) Hellenism rose to material supremacy in all the East as far as India, and when cities of Greek speech and constitution were planted at the cardinal points of intercourse within those lands. The Macedonian chiefs found their pride in being champions of Hellenism. Their courts were Greek in language and atmosphere. All kings liked to win the good word of the Greeks. All of them in some degree patronized Greek art and letters, and some sought fame for themselves as authors. Even the barbarian courts, their neighbours or vassals, were swayed by the dominant fashion. But by the courts alone Hellenism could never have been propagated far. Greek culture had been the product of the city-state, and Hellenism could not be dissevered from the city. It was upon the system of Greek and Macedonian cities, planted by Alexander and his successors, that their work rested. Rome, when it stepped into their place, safeguarded its continuance, and acted as a Hellenistic power.

The Character of the New Greek Cities.—The citizen bodies at the outset were really of Greek or Macedonian blood—soldiers who had served in the royal armies, or men attracted from the older Greek cities to the new lands thrown open to commerce. The cities, of course, drew in numbers beside of the people of the land. The cities were Hellenic in their political organs and functions, with *boulē* and *demos* and popularly elected magistrates. Life was filled with the universal Hellenic interests, which centred in the gymnasium and the religious festivals, these last including, of course, not only athletic contests but performances of the classical dramas or later imitations of them. The wandering sophist and rhetorician would find a hearing no less than the musical artist. The language of the upper classes was Greek; and the material background of building and decoration, of dress and furniture, was of Greek design. A greater regularity in the street-plans distinguished the new cities from the older, slowly grown cities of the Greek lands.

Sometimes the Greek city was not an absolutely new foundation, but an old oriental city re-colonized and transformed. And in such cases the old name was often replaced by a Greek one. Even where there was no new foundation the older cities of Phoenicia and Syria became transformed from the overwhelming prestige of Hellenic culture. In Tyre and Sidon, no less than in Antioch or Alexandria, Greek literature and philosophy were seriously cultivated, as we may see by the great names which they contributed.

A. CHARACTERISTICS OF HELLENISM AFTER ALEXANDER

Hellenism had been the product of the free life of the Greek city-state, and after the Macedonian conquest the great days of the city-state were past. Not that all liberty was everywhere extinguished. In the history of the next two or three centuries the cities are by no means ciphers. Rhodes takes a great part in *Weltpolitik*, as a sovereign ally of one or other of the royal courts. In Greece itself the overlordship to which the Macedonian king aspires is imperfect in extent and only maintained by continual wars. The Greek States on their side show that they are capable even of progressive political development, the needs of the time being met by the federal system. The Achaean and Aetolian leagues are independent powers, which keep a field clear for Hellenic freedom within their borders. As to the cities outside Greece, within or around the royal realms, Seleucid, Ptolemaic or Attalid, their degree of freedom probably differed widely according to circumstances. At one end of the scale, cities of old renown could still make good their independence. At the other end of the scale the cities which were royal capitals, e.g., Alexandria, Antioch and Pergamum, were normally controlled altogether by royal nominees. Between the two extremes there was variation not only between city and city, but, no doubt, in one and the same city at different times. With the extension of the single strong rule of Rome over this Hellenistic world, the conditions were changed. Just as the Macedonian conquest, whilst increasing the domain of Greek culture, had straitened Greek liberty, so Rome, whilst bringing Hellenism finally into secure possession of the nearer East, extinguished Greek freedom altogether. Even now the old forms were long religiously respected. Formally, the most illustrious Greek states, Athens, for instance, or Marseilles, or Rhodes, were not subjects of Rome, but free allies. Even in the case of tribute-paying states, municipal autonomy, subject indeed to interference on the part of the Roman governor, was allowed to go on. But during the first centuries of the Christian era, this municipal autonomy decayed. The *demos* first sank into political annihilation and the council, no longer popularly elected but an aristocratic order, concentrated the whole administration in its hands. After Diocletian and under the Eastern empire the Greek world was organized on the principles of a vast bureaucracy.

Social Changes.—With this long process of political decline correspond the inner changes in the temper of the Hellenistic peoples. When the vast field of the East was opened to Hellenic enterprise and the bullion of its treasuries flung abroad, fortunes were made on a scale before unparalleled. A new standard of sumptuousness and splendour was set up in the richest stratum of

society. This material elaboration of life was furthered by the existence of Hellenistic courts, where the great ministers amassed fabulous riches, and of huge cities like Alexandria, Antioch and the enlarged Ephesus. With the mingling of Greeks of all sorts in the newly-conquered lands, a generalized Greek culture, in which the old local characteristics were merged, overspread the world. The gradual supersession of the old dialects by the *koinē* the common speech of the Greeks, was one obvious sign of the new order of things. (See GREEK LANGUAGE.)

Art and Literature.—In its artistic, its literary, its spiritual products the age after Alexander gave evidence of change. In no department did activity immediately stop; but the old freshness and creative exuberance was gone. Artistic pleasure, grown less delicate, required the stimulus of a more sensational effect or a more striking realism. Artists and men of letters were now addressing themselves not to their fellow-citizens in a free city, but to kings and courtiers, or the educated class generally of the Greek world. In the study of the world of fact, the centuries immediately following Alexander witnessed notable advance. Scientific research might prosper under the patronage of kings, and such research had now a vast amount of new material at its disposal and could profit by the old Babylonian and Egyptian traditions. The medical schools, especially that of Alexandria, really enlarged knowledge of the animal frame. Knowledge of the earth gained immensely by the Macedonian conquests. The literary schools of Alexandria and Pergamum built up grammatical science, and brought literary and artistic criticism to a fine point. The classical products were registered, studied and commented upon. Libraries became a feature of the age; the one attached to the Museum at Alexandria is said to have contained 700,000 rolls.

With the general decay of ancient civilization under the Roman empire, even scientific research ceased, and though there were literary revivals, like that connected with the new Atticism under the Antonine emperors, these were mainly imitative and artificial, and learning became under the Byzantine emperors a formal tradition. (See GREEK LITERATURE.)

Religion and Philosophy.—The mingling of citizens of many cities and the close contact between Greek and barbarian in the conquered lands had made the old sanctions of civic religion and morality of less account. New guides of life were needed. The Stoic philosophy, with its cosmopolitan note, its fixed dogmas and plain ethical precepts came into the world to meet the needs of the new age. Its ideas became popular among ordinary men as the older philosophies had never been.

Although the cults of the old Greek deities in the new cities might still hold the multitude with their splendid apparatus, men turned ever in large numbers to alien religions, and the various gods of Egypt and the East began to find larger entrance in the Greek world. Before the end of the 2nd century B.C. there were temples of Serapis in Athens, Rhodes, Delos and elsewhere. Under the Roman empire the cult of Isis became popular in the Hellenistic world. Other religions of oriental origin penetrated far, the worship of the Phrygian Great Mother (see GREAT MOTHER OF THE GODS), and in the 2nd century A.D. the religion of Mithras (*q.v.*). The Jews, too, by the time of Christ were discovering in many quarters an open door. Besides those who were ready to accept circumcision, numbers adopted particular Jewish practices, observing the Sabbath, for instance, or turned from polytheism to the doctrine of the One God. The synagogues in the Gentile cities had generally attached to them a multitude of those "who feared God" and frequented the services.

Christianity.—Among the religions which penetrated the Hellenistic world from an Eastern source, Christianity ultimately overpowered all the rest and made that world its own. The teaching of Christ Himself contained, as it is given to us, no Hellenic element; so far as He built with older material, that material was exclusively the sacred tradition of Israel. So soon, however, as the Gospel was carried in Greek to Greeks, Hellenic elements began to enter into it; in the writings of St. Paul the appeal to what "nature" teaches would be generally admitted to be a Greek mode of thought. There was, at the same time, in the early

church a powerful current of feeling hostile to Greek culture. What the attitude of the New People should be to it, whether it was all bad, or whether there were good things in it which Christians should appropriate, was a vital question to them. The School of Alexandria represented by Clement and Origen effected a durable alliance between Greek education and Christian doctrine. In proportion as the Christian Church had to go deeper into metaphysics in the formulation of its beliefs, the Greek philosophical terminology, which was the only vehicle then available for precise thought, had to become more and more an essential part of Christianity. At the same time Christian ethics incorporated much of the current popular philosophy, especially Stoical elements. In this way the Church itself became a propagator of Hellenism.

B. EFFECT UPON NON-HELLENIC PEOPLES

1. **India.**—In India (including the valleys of the Kabul and its northern tributaries, then inhabited by an Indian, not as now, by an Iranian, population), Alexander planted a number of Greek towns. Soon after 321 B.C. Macedonian supremacy beyond the Indus collapsed before the advance of the native Maurya dynasty, and about 303 B.C. large districts west of the Indus were ceded by Seleucus. But the Maurya dynasty broke up about 180 B.C., and at the same time the Greek rulers of Bactria began to lead expeditions across the Hindu-Kush. Menander, in the middle of the 2nd century B.C., extended his rule to the Ganges. Then "Scythian" peoples from Central Asia gradually squeezed within ever-narrowing limits the Greek power in India. The last Greek prince, Hermaeus, seems to have succumbed about 30 B.C. Under the Roman empire, though Greek rule in India had disappeared, active commercial intercourse went on between India and the Hellenistic lands. How far, through these changes, did the Greek population settled by Alexander or his successors in India maintain their distinctive character? What influence did Hellenism, during the centuries in which it was in contact with India, exert upon the native mind? Only extremely qualified answers can be given to these questions. Capital data are possibly waiting under ground—the Kabul valley, for instance, is almost virgin soil for the archaeologist—and any conclusion we can arrive at is merely provisional. If certain statements of classical authors were true, Hellenism in India flourished exceedingly. But the phil-Hellenic Brahmins in Philostratus' life of Apollonius had no real existence, and the statement of Dio Chrysostom that the Indians were familiar with Homer in their own tongue is a traveller's tale. India has yielded no Greek inscription except on the coins of the Greek kings and their Scythian successors. If we argue by probability from what we know of the conditions, we have to consider that the Greek rule in India was all through fighting for existence, and can have had little time or energy left for such things as art, science and literature. Perhaps we should rather think of the Hellenic colonists as resembling the Greeks found to-day dispersed over the nearer East, with interests mainly commercial, easily assimilating themselves to their environment. As to what India derived from Greece there has been a good deal of erudite debate. That the Indian drama took its origin from the Greek is still maintained by some scholars, though hardly proved. There is no doubt that Indian astronomy shows marked Hellenic features, including actual Greek words borrowed. But by far the most signal borrowing is in the sphere of art. The stream of Buddhist art which went out eastwards across Asia had its rise in North-West India, and the remains of architecture and sculpture unearthed in this region enable us to trace its development back to pure Greek types. How far to the east the distinctive influence of Greece went is shown by the seal-impressions with Athena and Eros types, the stucco reliefs and antefixes, and the frescoes found by Sir Marc Aurel Stein in the buried cities of Khotan. These remains belong to the period of the early and middle Roman empire, and were probably the work of Hellenized orientals rather than of Greeks; but their Hellenic character is unmistakable. According to Mr. E. B. Havell, there exist "paintings treasured as the most precious relics and rarely shown to Europeans, which closely resemble the Graeco-Buddhist art of India" in some of the oldest temples of Japan (*Studio*, vol. xxvii., 1903, p. 26).

2. **Iran and Babylonia.**—The colonizing activity of Alexander and his successors found a large field in Iran. Cities arose in all its provinces. Media was defended by a chain of Greek cities from barbarian incursion. In Eastern Iran the cities which are its chief places to-day then bore Greek names, and looked upon Alexander or some other Hellenic prince as their founder. Khojend, Herat, Kandahar were Alexandrias, Merv was an Alexandria till it changed that name for Antioch. One document from Antioch in Persis (about 206 B.C.) shows us the normal organs of a Greek city in full working. It also throws a remarkable light upon the solidarity of the Hellenic dispersion. The citizen body had been increased some generations before by colonists from Magnesia-on-Meander, and in this decree Antioch determines to take part in the new festival being started in honour of Artemis at Magnesia.

Greek Kingdoms.—About 250 B.C. Bactria and Sogdiana broke away from the Seleucid empire; independent Greek kings reigned there till the country was conquered by nomads from Central Asia a century later. Alexander had settled large masses of Greeks in these regions. For estimating the amount and quality of Hellenism in Bactria during the 180 years or so of Macedonian and Greek rule, we are reduced to building hypotheses upon the scantiest data. Mr. W. W. Tarn's careful survey leads to the conclusion that palpable evidences of an active Hellenism have not been found; he inclines to think that the Greek kingdoms mainly took on the native Iranian colour. The coins, of course, are adduced on the other side, being not only Greek in type and legend, but (in many cases) of a peculiarly fine execution. (See BACTRIA and works there quoted.)

The west of Iran slipped from the Seleucids in the course of the 2nd century B.C., to be joined to the Parthian kingdom or fall under petty native dynasties. Soon after 130 B.C. Babylonia, too, was conquered by the Parthian, and Mesopotamia before 88. Then the reconquest of the nearer East by Oriental dynasties was checked by the advance of Rome. Asia Minor and Syria remained substantial parts of the Roman empire until the Mohammedan conquests of the 7th century A.D. began a new process of recoil on the part of the Hellenistic power. The greatest of all the Hellenic colonies stood here—almost on the site of Bagdad—Seleucia on the Tigris. It superseded Babylon as the industrial focus of Babylonia and counted some 600,000 inhabitants. In Mesopotamia, Pliny especially notes how the character of the country was changed when the old village life was broken in upon by new centres of population in the cities of Macedonian foundation.

Hellenic Iranian Culture.—When the Parthians rent away provinces from the Seleucid empire, the Greek cities did not cease to exist by passing under barbarian rule. Gradually, no doubt, the Greek colonies were absorbed, but the process was a long one. Seleucia on the Tigris is spoken of by Tacitus as being, in A.D. 36, "proof against barbarian influences." How important an element the Greek population of their realm seemed to the Parthian kings we can see by the fact that they claimed to be themselves champions of Hellenism. From the reign of Artabanus I. (128/7–123 B.C.) they bear the epithet of "Phil-Hellen" as a regular part of their title upon the coins. That the Parthian court itself was to some extent Hellenized is shown by the story that a Greek company of actors was performing the *Bacchae* before the king when the head of Crassus was brought in. Artavasdes, king of Armenia (54?–34 B.C.) composed Greek tragedies and histories. The Parthian princes were in many cases the children of Greek mothers who had been taken into the royal harems. Many of the Parthian princes resided temporarily, as hostages or refugees, in the Roman empire; but the nation at large looked with anything but favour upon too liberal an introduction of foreign manners at the court.

Such slight notices in Western literature do not give us any penetrating view into the operation of Hellenism among the Iranians. As an expression of the Iranian mind we have the Avesta and the Pehlevi theological literature. Unfortunately, in a question of this kind the dating of our documents is the first matter of importance; and we can only assign dates to the differ-

ent parts of the Avesta by processes of fine-drawn conjecture. And even if we could date the Avesta securely, we could only prove borrowing by more or less close coincidences of idea, a tempting but uncertain method of enquiry. It is enough here to observe that Iran and Babylonia do, as a matter of fact, continually yield the explorer objects of workmanship either Greek or influenced by Greek models, belonging to the age after Alexander, and that we may hence infer at any rate such an influence of Hellenism upon the tastes of the richer classes as would create a demand for these things.

Sassanian Empire.—If any vestige of Hellenism still survived under the Sassanian kings, our records do not show it. At the court a limited recognition might be given, as fashion veered, to the values prevalent in the Hellenistic world. Chosroes I. interested himself in Greek philosophy and received its professors from the West with open arms; according to one account, he had his palace at Ctesiphon built by Greeks. But the account of Chosroes' mode of action makes it plain that the Hellenism once planted in Iran had withered away; representatives of Greek learning and skill had all to be imported from across the frontier.

3. **Asia Minor.**—**Greek Cities of the Diadochi.**—Very different were the fortunes of Hellenism in those lands which became annexed to the Roman empire. In Asia Minor, we have seen how, even before Alexander, Hellenism had begun to affect the native races and Persian nobility. During Alexander's own reign, we cannot trace any progress in the Hellenization of the interior, nor can we prove here his activity as a builder of cities. But under the dynasties of his successors a great work of colonization went on as each rival dynasty of Greek or Macedonian kings endeavoured to secure its hold on the country by founding fresh Greek settlements. While new Greek cities were rising in the interior, the older Hellenism of the western coast grew in material splendour under the munificence of Hellenistic kings. Its centre of gravity to some extent shifted. Ephesus grew in greatness and wealth, and Smyrna rose again after an extinction of four centuries. The great importance of Rhodes belongs to the days after Alexander, when it received the riches of the East from the trade-routes which debouched into the Mediterranean at Alexandria and Antioch. In Aeolis the centre of gravity moved to the Attalid capital, Pergamum. But the irruption of the Celts, beginning in 278–277 B.C., checked the Hellenization of the interior. Not only did the Galatian tribes take large tracts of the plateau in possession, but they were an element of perpetual unrest, which hampered and distracted the Hellenistic monarchies.

Native Dynasties.—The minor dynasties of non-Greek origin, the native Bithynian and the two Persian dynasties in Pontus and Cappadocia, were Hellenized before the Romans drove the Seleucid out of the country. In Bithynia the upper classes seem to have followed the fashion of the court; the dynasty of Pontus was phil-Hellenic by ancestral tradition; the dynasty of Cappadocia dated its conversion to Hellenism from the 2nd century B.C.

Hellenism under Rome.—When Rome began to interfere in Asia Minor, its first action was to break the power of the Gauls (189 B.C.). In 133 Rome entered formally upon the heritage of the Attalid kingdom and became the dominant power in the Anatolian peninsula for 1,200 years. Under Rome the process of Hellenization, which the divisions and weakness of the Macedonian kingdoms had checked, went forward. The coast regions of the west and south the Romans found already Hellenized. In Lydia not a trace of the old language was left in Strabo's time; in Lycia, the old language became obsolete in the early days of Macedonian rule. But inland, in Phrygia, Hellenism had as yet made little headway outside the Greek cities. It was not until the reign of Hadrian that city life on the Phrygian plateau became rich and vigorous, with its material circumstances of temples, theatres and baths. The lower classes at Lystra in St. Paul's time spoke Lycaonian (Acts xiv. 11). In Galatia the larger towns seem to have become Hellenized by the time of the Christian era, whilst the Celtic speech maintained itself in the country villages until the 4th century A.D. Cappadocia at the beginning of the Christian era was still comparatively townless, a country

of large estates with a servile peasantry. Even in the 4th century its Hellenization was still far from complete; but Christianity had assimilated so much of the older Hellenic culture that the Church was now a main propagator of Hellenism in the backward regions. The native languages of Asia Minor all ultimately gave way to Greek. The effective Hellenization of Armenia did not take place until the 5th century.

4. **Syria.**—In Syria the work of planting cities was pursued effectively north of the Lebanon by the house of Seleucus, and, less energetically, south of the Lebanon by the house of Ptolemy.

Seleucid Empire.—The whole of Syria was brought under the Seleucid sceptre, together with Cilicia, by Antiochus III. (223-187 B.C.). Under his son, Antiochus IV. (175-164), a fresh impulse was given to Syrian Hellenism. In 1 Maccabees he is represented as writing an order to all his subjects to forsake the ways of their fathers and conform to a single prescribed pattern, and though in this form the account can hardly be exact, it does no doubt represent the spirit of his action. Many cities exchanged their existing name for that of Antioch. With the ever-growing weakness of the Seleucid dynasty, the independence and activity of the cities increased, although they were less protected against military adventures and barbarian chieftains.

Roman Period.—When Pompey annexed Syria in 64 B.C. as a Roman province, he found it a chaos of city-states and petty principalities. The Nabataeans and the Jews above all had encroached upon the Hellenistic domain; in the south the Jewish raids had spread desolation and left many cities practically in ruins. Under Roman protection Hellenism was secured from the barbarian peril, and Greek city life, with its political forms, its complement of festivities, amusements and intellectual exercise, went on more largely than before. The great majority of the Hellenistic remains in Syria belong to the Roman period. Such local dynasties as were suffered by the Romans to exist had, of course, a Hellenistic complexion. Especially was this the case with that of the Herods. Not only were such marks of Hellenism as a theatre introduced by Herod the Great (37-4 B.C.) at Jerusalem, but in the work of city-building this dynasty showed itself active. Sebaste (the old Samaria), Caesarea, Antipatris were built by Herod the Great, Tiberias by Herod Antipas (4 B.C.-A.D. 39). In Syria, too, Hellenism under the Romans advanced upon new ground. Palmyra, of which we hear nothing before Roman times, is a notable instance.

Greek Culture in Syria.—In Syria we do not find the same disappearance of native languages and racial characteristics as in Asia Minor. Still less was this the case in Mesopotamia. At Doura-Europus on the middle Euphrates recent excavations have presented the picture of a Seleucid foundation, built and decorated in good Greek style, but unable to resist Semitic encroachments. By A.D. 300 even the people of the wealthier classes usually bear Semitic names. The lower classes at Antioch and no doubt in the cities generally, were in speech Aramaic or bilingual. The villages, of course, spoke Aramaic. The richer natives, on the other hand would become Hellenized in language and manners, and the "Syrian Code" of civil laws shows how far the social structure was modified by the Hellenic tradition. Of the Syrians who made their mark in Greek literature, some were of native blood; e.g., Lucian of Samosata, and several later poets and philosophers.

On the other hand there was a Syriac-speaking church as early as the 2nd century, and with the spread of Christianity Syriac asserted itself against Greek. The Syriac literature which we possess is all Christian. But where Greek gave place to Syriac, Hellenism was not thereby effaced. It was to some extent the passing over of the Hellenic tradition into a new medium. There was an extensive translation of Greek works into Syriac during the next centuries, handbooks of philosophy and science for the most part.

5. **Hellenism and the Jews.**—In the first century and a half of Macedonian rule the relation of the Jews to Hellenism is very obscure, since the statements made by later writers, like Josephus, as to the privileges conferred upon the Jews in the new Macedonian realms, are justly suspected of being fiction. It has been maintained that Greek influence is to be traced in parts of

the Old Testament assigned to this period, as, for instance, the Book of Proverbs; but even in the case of Ecclesiastes, the canonical writing whose affinity with Greek thought is closest, the coincidence of idea need not necessarily prove a Greek source. The one solid fact in this connection is the translation of the Jewish Law into Greek in the 3rd century B.C., implying a Jewish Diaspora at Alexandria, so far Hellenized as to have forgotten the speech of Palestine. Early in the 2nd century B.C. the priestly aristocracy of Jerusalem had, like the well-to-do classes everywhere in Syria, been carried away by the Hellenistic current, its strength being evidenced no less by the intensity of the conservative opposition embodied in the party of the "Pious" (*Assideans*, *Hasidim*). Under Antiochus IV. (176-165) the Hellenistic aristocracy contrived to get Jerusalem converted into a Greek city; the gymnasium appeared, and Greek dress became fashionable with the young men. But when Antiochus, for political reasons, interfered violently at Jerusalem, the conservative opposition carried the nation with them. The revolt under the Hasmonaeans family (Judas Maccabaeus and his brethren) followed, ending in 143-142 in the establishment of an independent Jewish state. But the Hasmonaeans state was of the nature of a compromise. The Mosaic Law was respected, but Hellenism still found an entrance in various forms. The first Hasmonaeans king, Aristobulus I. (104-103), was known to the Greeks as Phil-Hellen. He and all later kings of the dynasty bear Greek names as well as Hebrew ones, and after Iannaeus Alexander (103-76) the Greek legends are common on the coins beside the Hebrew. Herod, who supplanted the Hasmonaeans dynasty (37-4 B.C.) made, outside Judaea, a display of phil-Hellenism, building new Greek cities and temples. His court, at the same time, welcomed Greek men of letters like Nicolaus of Damascus. Even in the neighbourhood of Jerusalem, he erected a theatre and an amphitheatre. Meanwhile a great part of the Jewish people was living dispersed among the cities of the Greek world, speaking Greek as their mother-tongue. These are the Jews whom we find contrasted as "Hellenists" with the "Hebrews" in Acts. A large Jewish literature in Greek had grown up since the translation of the Law in the 3rd century. Beside the other canonical books of the Old Testament, it included translations of other Hebrew books (*Ecclesiasticus*, *Judith*, etc.); works composed originally in Greek but imitating to some extent the Hebraic style (like *Wisdom*); works modelled more closely on the Greek literary tradition, either historical, like 2 Maccabees, or philosophical, like the productions of the Alexandrian school, represented for us by Aristobulus and Philon; or Greek poems on Jewish subjects, like the epic of the elder Philon and Ezechiel's tragedy, *Exagôgê*. It included also a number of forgeries contrived for the heathen public, as a means of propaganda, calculated to inspire them with respect for Jewish antiquity or turn them from idols to God.

Through the Hellenistic Jews, Greek influences reached Jerusalem itself, though their effect upon the Aramaic-speaking Rabbinical schools was naturally not so pronounced. The large number of Greek words, however, in the language of the Mishnah and the Talmud is a significant phenomenon. The attitude of the Rabbinical doctors to a Greek education does not seem to have been hostile until the time of Hadrian. The sect of the Essenes probably shows an intermingling of the Greek with other lines of tradition among the Jews of Palestine.

6. **Egypt and Aethiopia.**—In Egypt the Ptolemies were hindered by special considerations from building Greek cities after the manner of the other Macedonian houses. Even at Alexandria Hellenism was not allowed full development. In its population, too, Alexandria was only semi-Hellenic; for besides the proportion of Egyptian natives in its lower strata, its commercial greatness drew in elements from every quarter; the Jews, for instance, formed a majority of the population in two out of the five divisions of the city. At the same time the prevalent tone of the populace was, no doubt, Hellenistic, as is shown by the fact that the Jews who settled there acquired Greek in place of Aramaic as their mother-tongue, and in its upper circles Alexandrian society under the Ptolemies was not only Hellenistic, but notable among the Hellenes for its literary and artistic brilliance. The

State university, the "Museum," was in close connection with the court, and gave to Alexandria the same pre-eminence in natural science and literary scholarship which Athens had in moral philosophy. Probably in no other country, except Judaea, did Hellenism encounter as stubborn a national antagonism as in Egypt. Yet the papyri show us habitual marriage of Greeks and native women, and a frequent adoption by natives of Greek names. In Egypt, too, the triumph of Christianity brought into being a native Christian literature, and if this was in one way the assertion of the native against Hellenistic predominance, one must remember that Coptic literature, like Syriac, necessarily incorporated those Greek elements which had become an essential part of Christian theology.

From the Ptolemaic kingdom Hellenism early travelled up the Nile into Aethiopia. Ergamenes, the king of the Aethiopians in the time of the second Ptolemy, who had received a Greek education and cultivated philosophy, broke with the native priesthood, and from that time traces of Greek influence continue to be found in the monuments of the Upper Nile. When Aethiopia became a Christian country in the 4th century, its connection with the Hellenistic world became close.

7. **Hellenism in the West.**—Whilst in the East Hellenism had been sustained by the political supremacy of the Greeks, in Italy *Graecia capta* had only the inherent power and charm of her culture wherewith to win her way. Even before Alexander, as we saw, Hellenism had affected the peoples of Italy, but it was not until the Greeks of South Italy and Sicily were brought under the supremacy of Rome in the 3rd century B.C. that the stream of Greek influence entered Rome in any volume. It was now that the Greek freedman, L. Livius Andronicus, laid the foundation of a new Latin literature by his translation of the *Odyssey*, and that the Greek dramas were recast in a Latin mould. The first Romans who set about writing history wrote in Greek. At the end of the 3rd century there was a circle of enthusiastic phil-Hellenes among the Roman aristocracy, led by Titus Quinctius Flamininus, who in Rome's name proclaimed the autonomy of the Greeks in 196. In the middle of the 2nd century B.C. Roman Hellenism centred in the circle of Scipio Aemilianus, which included men like Polybius and the philosopher Panaetius. The visit of the three great philosophers, Diogenes, Critolaus and Carneades in 155, was an epoch-making event in the history of Hellenism at Rome. Opposition there could not fail to be, and in 161 a *senatus consultum* ordered all Greek philosophers and rhetoricians to leave the city. The effect of such measures was, of course, transient. Even though the opposition found so doughty a champion as the elder Cato (censor in 184), it was ultimately of no avail. The Italians did not indeed surrender themselves passively to the Greek tradition. In different departments of culture the degree of their independence was different. The mere fact that they produced a literature in Latin argues a power of creation as well as receptivity. The great Latin poets were imitators indeed, but mere imitators they were no more than Petrarch or Milton. On the other hand, even where the creative originality of Rome was most pronounced, as in the sphere of law, there were elements of Hellenic origin. It has been often pointed out how the Stoic philosophy especially helped to shape Roman jurisprudence.

While the upper classes in Italy absorbed Greek influences by their education, the lower strata of the population of Rome became largely Hellenized by the actual influx on a vast scale of Greeks and Hellenized Asiatics, brought in for the most part as slaves, and coalescing as freedmen with the citizen body. The early Christian Church in Rome, to which St. Paul addressed his epistle, was Greek-speaking, and continued to be so until far into the 3rd century. In the western Mediterranean a Greek element was introduced wherever the Romans fostered town life and thus invited the Greek trader and professional man. This later process of Hellenization is especially noticeable in North Africa, where the native king, Juba (under Augustus) actively encouraged it. But in the West the Latin language everywhere ousted the Greek as a spoken tongue, and the prevalent culture was Italian rather than Hellenic.

III. LATER HISTORY

It remains only to glance at the ultimate destinies of Hellenism in West and East. In the Latin West, knowledge of Greek, first-hand acquaintance with the Greek classics, became rarer and rarer as general culture declined, until in the dark ages (after the 5th century) it existed practically nowhere but in Ireland. In Latin literature, however, a great mass of Hellenistic tradition was maintained in currency, wherever culture of any kind continued to exist. Then the stream began to rise again, first with the influx of the learning of the Spanish Moors, then with the new knowledge of Greek brought from Constantinople in the 14th century. With the Renaissance and the new learning, Hellenism came in again in flood, to form a chief part of that great river on which the modern world is being carried forward. In the East it is popularly thought that Hellenism, as an exotic, withered altogether away. This view is superficial. Ultimately the Greek East was absorbed by Islam; the popular mistake lies in supposing that the Hellenistic tradition thereby came to an end. The Mohammedan conquerors found a considerable part of it taken over, as we saw, by the Syrian Christians, and Greek philosophical and scientific classics were now translated from Syriac into Arabic. These were the starting-points for the Mohammedan schools in these subjects. Accordingly we find the Arabian philosophy (*q.v.*), mathematics, geography, medicine and philology are all based professedly upon Greek works. Aristotle in the East no less than in the West was the "master of them that know"; the geography and astronomy of Claudius Ptolemaeus had canonical authority in Islam and in Christendom alike; and Muslim physicians to this day invoke the names of Hippocrates and Galen. The Hellenistic strain in Mohammedan civilization has, it is true, flagged and failed, but only as that civilization as a whole has declined.

BIBLIOGRAPHY.—(a) *General books on Hellenism*: W. W. Tarn, *Hellenistic Civilisation* (1927), a good select bibliography; J. B. Bury and others, *The Hellenistic Age* (1923); J. P. Mahaffy, *The Progress of Hellenism in Alexander's Empire* (1905), and *The Silver Age of the Greek World* (1906); J. Kaerst, *Geschichte des Hellenismus* (1917-26); K. J. Beloch, *Griechische Geschichte*, vol. iv. part 1 (1925); Th. Birt, *Alexander der Grosse und das Weltgriechentum* (1924); P. Jouguet, *L'impérialisme macédonien et l'hellénisation de l'Orient* (1926), good bibliography.

(M. C.)

HELLER, STEPHEN (1815-1888), Austrian pianist and composer, was born at Pest on May 15, 1814. He studied at Vienna under Czerny and Halm. For some years he played as a *Wunderkind*, but in 1838, settled in Paris, where he became intimate with Liszt, Chopin, Berlioz and their circle, among whom was Hallé, throughout his life an admirer of Heller's music. But Heller outlived the great reputation which he had enjoyed among cultivated amateurs for so many years, and was almost forgotten when he died in Paris on Jan. 14, 1888.

HELLES, LANDING AT, 1915: see DARDANELLES CAMPAIGN.

HELLESPONT (i.e., "Sea of Helle"; variously named in classical literature 'Ελλάσποντος, ὁ 'Ελλήσπόντος, *Hellespontum Pelagus*, and *Fretum Helleponticum*), the ancient name of the Dardanelles (q.v.). It was so-called from Helle, the daughter of Athamas (q.v.), who was drowned here. See ARGONAUTS.

HELLEVOETSLUIS or **HELVOETSLUIS**, a fortified seaport in the province of South Holland, on the south side of the island of Voorne-and-Putten, 5½ m. S. of Brielle. It has a daily steamboat service with Rotterdam by the Voornsche canal. Pop. (1926) 2,324. Hellevoetsluis was formerly a naval station.

HELLÍN, the *Illunum* of the Romano, a town of south-eastern Spain, in the province of Albacete, on the Albacete-Murcia railway. Pop. (1921) 10,967. Hellín is built on the outskirts of the low hills which line the left bank of the river Mundo. It possesses the remains of a Roman castle and has a fine parish church. The surrounding country yields wine, oil and saffron. Within the town there are manufactures of cloth, leather and pottery. Sulphur is obtained from the mining district of Minas del Mundo, 12 m. S., at the junction between the Mundo and the Segura; and there are warm sulphurous springs in the neighbouring village of Azaraque.

HELLO, ERNEST (1828-1885), French critic, was born in Tréguier. His best-known book, *Physionomie de saints* (1875), which has been translated into English (1903) as *Studies in Saintship*, does not display his qualities best. The real Hello is to be found in a series of philosophical and critical essays, from *Renan, l'Allemagne et l'athéisme* (1861), through *L'Homme* (1871) and *Les Plateaux de la balance* (1880), perhaps his best work, to the posthumously published *Le Siècle*. His studies of Shakespeare, Hugo and others are of abiding importance.

HELMERS, JAN FREDERIK (1767-1813), Dutch poet, was born at Amsterdam on March 7, 1767. His *Poems* (2 vols., 1809-10), but especially his great work *De Hollandsche Natie* (1812), a poem in six cantos directed against Napoleon, created great enthusiasm. Helmers died at Amsterdam on Feb. 26, 1813.

HELMERSEN, GREGOR VON (1803-1885), Russian geologist, was born at Laugut-Duckershof, near Dorpat, on Sept. 29 (O.S.) 1803. He received an engineering training and became major-general in the corps of mining engineers. In 1837 he was appointed professor of geology in the mining institute at St. Petersburg. He wrote *Studien über die Wanderblöcke und die Diluvialgebilde Russlands* (1869 and 1882). Most of his memoirs were published by the Imperial Academy of Sciences at St. Petersburg. He died at St. Petersburg on Feb. 3 (O.S.) 1885.

HELMET, a defensive covering for the head. The present article deals with the helmet during the middle ages down to the close of the period when body armour was worn. For the helmet worn by the Greeks and Romans see ARMS AND ARMOUR.

The head-dress of the warriors of the dark ages and of the earlier feudal period was far from being the elaborate helmet

FIG. 1.—ANGLO-SAXON SPEARMAN OF THE 11TH CENTURY (FROM COTTON MS., CLAUDIUS B. IV.)

which is associated in the imagination with the knight in armour and the tourney. It was a mere casque, a cap with or without additional safeguards for the ears, the nape of the neck and the nose (fig. 1). By those warriors who possessed the means to equip and protect themselves more fully, the casque was worn over a hood of mail. In manuscripts, armoured men are sometimes portrayed fighting in their hoods, without casques, basinet or other form of helmet. The casque was, of course, normally of plate, but in some instances it was a strong leather cap covered with mail or imbricated plates. The most advanced form of this early helmet is the conical steel or iron cap with nasal; it was worn in conjunction with the hood of mail. This is the typical helmet of the 11th-century warrior, and is made familiar by the Bayeux Tapestry. From this point however (c. 1100) the evolution of war head-gear follows two different paths for many years. On the one hand the simple casque easily transformed itself into the

basinet, originally a pointed iron skull-cap without nasal, ear-guards, etc. On the other hand the knight in armour, especially after the fashion of the tournament set in, found the mere cap with nasal insufficient, and the *heaume* (or "helmet") gradually came into vogue. This was in principle a large heavy iron pot covering the head and neck. Often a light basinet was worn underneath

FIG. 2.—FIGURE IN ARMOUR ON HORSEBACK ON THE GREAT SEAL OF HENRY III.

it—or rather the knight usually wore his basinet and only put the heaume on over it at the last moment before engaging. The earlier (12th century) war heaumes are intended to be worn with the mail hood and have nasals. Towards the close of the 13th century, however, the basinet grew in size and strength, just as the casque had grown, and began to challenge comparison with the heavy and clumsy heaume. Thereupon the heaume, became, by degrees, the special head-dress of the tournament,

and grew heavier, larger and more elaborate, while the basinet, reinforced with camail and vizor, was worn in battle.

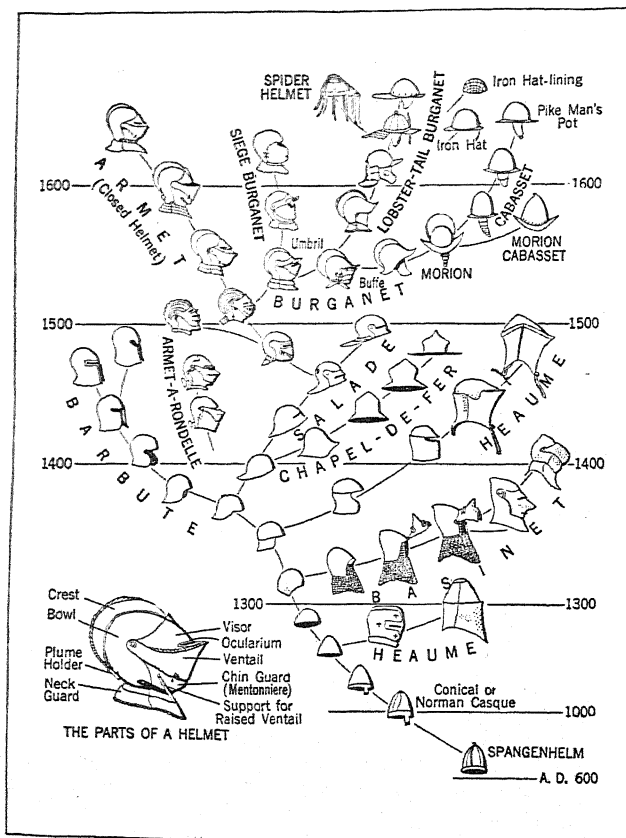

The basinet, then, is the battle head-dress of nobles, knights and sergeants in the 14th century. Its development from the 10th-century cap to the towering helmet of 1350, with its long snouted vizor and ample drooping "camail," is shown in fig. 5, two of the examples given showing the same helmet but with vizor down and up. But the tendency set in during the 15th century to make all parts of the armour thicker. Chain "mail" gradually gave way to plate on the body and limbs, remaining only in those parts, such as neck and elbows, where flexibility was essential, and even there it was in the end replaced by jointed steel bands or small plates. The final step was the discarding of the "camail" and the introduction of the "armet." The latter will be described later. Soon after the beginning of the 15th century the high-crowned basinet gave place to the *salade* or *sallet*, a helmet with a low rounded crown and a long brim or neck-guard at the back. This was the typical head-piece of the last half of the Hundred Years' War as the vizored basinet had been of the first. Like the basinet it was worn in a simple form by archers and pikemen and in a more elaborate form by knights and men-at-arms. The larger and heavier salades were also often used instead of the heaume in tournaments. Here again, however, there is a great difference between those worn by light armed men, foot-soldiers and archers and those of the heavy cavalry. The former, while possessing as a rule the bowl shape and the lip or brim of the type, and always destitute of the conical point which is the distinguishing mark of the basinet, are cut away in front of the face (fig. 7a). In some cases this was remedied in part by the addition of a small pivoted vizor, which, however, could not protect the throat. In the larger salades of the heavy cavalry the wide brim served to protect the whole head, a slit being made in that part of the brim which came in front of the eyes (in some examples the whole of the front part of the brim was made movable). But the chin and neck, directly opposed to the enemy's blows, were scarcely protected at all, and

FIG. 4.—BARENDYNE HELM, GREAT HASELEY, OXFORD. WEIGHT 13 LBS., 8 OZS.

with these helmets, a large volant-piece or beaver (*mentonnière*)—usually a continuation of the body armour up to the chin or even beyond—was worn for this purpose, as shown in fig. 7*b*. This arrangement combined, in a rough way, the advantages of freedom of movement for the head with adequate protection for the neck

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, NEW YORK
FIG. 5.—DEVELOPMENT OF THE HELMET FROM 600 A.D. TO THE 17TH CENTURY

and lower part of the face. The *armet*, which came into use about 1475-1500 and completely superseded the *salade*, realized these requirements far better, and later at the zenith of the armourer's art (about 1520) and throughout the period of the decline of armour it remained the standard pattern of helmet, whether for war or for tournament. It figures indeed in nearly all portraits of kings, nobles and soldiers up to the time of Frederick the Great, appearing with the suits of armour or half-armour worn by the subjects, and also in allegorical trophies, etc. The *armet* was a fairly close-fitting rounded shell of iron or steel, with a movable vizor in front and complete plating over chin, ears and neck, the latter replacing the *mentonnière* or beaver. The *armet* was connected to the rest of the suit by the gorget, which was usually of thin laminated steel plates. With a good *armet* and gorget there was no weak point for the enemy's sword to attack, a roped lower edge of the *armet* generally fitting into a sort of flange round the top of the gorget. Thus, and in other and slightly different ways, was solved the problem which in the early days of plate armour had been attempted by the clumsy *heaume* and the flexible, if tough, camail of the vizored *basinet*, and still more clumsily in the succeeding period by the *salade*, and its grotesque *mentonnière*. As existing examples show, the wide-brimmed *sallet* (*salade* or *sallad*) gave way to the rounded *armet*, the *mentonnière* being carried up to the level of the eyes. Then the use

(growing throughout the 15th century) of laminated armour for the joints of the harness probably suggested the gorget, and once this was applied to the lower edge of the *armet* by a satisfactory joint, it was an easy step to the elaborate pivoted vizor which completed the new head-dress. Types of armets are shown in fig. 8.

The *burgonet* or *burganet*, often confused with the *armet*, is typical of the late 16th and early 17th centuries. In its simple form it was worn by the foot and light cavalry—though the latter must not be held to include the pistol-armed *chevaux-légers* of the wars of religion, these being clad in half-armour and vizored *burgonet*—and consisted of a (generally rounded) cap with a projecting brim shielding the eyes, a neck-guard and ear-pieces. It had almost invariably a crest or comb, as shown in the illustrations (fig. 9). Other forms of infantry head-gear much in vogue in the 16th century were the *morion* and *cabasset*, both lighter and smaller than the *burgonet*; indeed, much of their

FIG. 9.—(A, B, C) BURGONETS, HEAD PIECES SUITED TO LIGHT HORSE; (D) ARMET, CLOSE HELMET

with the *burgonet*, which in one form or another was used by cavalry (and often by pikemen) up to the final disappearance of

armour from the field of battle about 1670. A richly decorated 16th-century Italian burgonet is in Vienna. Its archetype is perhaps the casque worn by the Swiss infantry at the epoch of Marignan (1515). This was probably copied by them from their former Burgundian antagonists, whose connection with this helmet is sufficiently indicated by its name. The lower part of the more elaborate burgonets worn by nobles and cavalymen is often formed into a complete covering for the ears, cheek and chin, connected closely with the gorget. They therefore resemble the armets and have often been confused with them, but the distinguishing feature of the burgonet is invariably the front peak. Various forms of vizor were fitted to such helmets; these as a rule were fixed bars or continuations of the chin piece. Often a nasal was the only face protection. The latest-form burgonet in active service is the familiar Cromwellian cavalry helmet with its straight brim, from which depends the slight vizor of three bars or stout wires joined together at the bottom.

The above are of course only the main types. Some writers class all remaining examples either as casques or as "war-hats," the latter term conveniently covering all those helmets which resemble in any way the head-gear of civil life. For illustrations of many curiosities of this sort, including the famous iron hat of King Charles I. of England, and also for examples of Russian, Mongolian, Indian and Chinese helmets, the reader is referred to pp. 262-269 and 285-286 of Demmin's *Arms and Armour* (English edition 1894).

Modern Steel Helmets.—During the World War the conditions of trench warfare left the head exposed to danger more than any other part of the body. In addition to this the increased employment of shrapnel against troops caused the proportion of head wounds to rise considerably. To meet these circumstances the French devised a steel helmet weighing 22 oz. and brought it into use in the spring of 1915. It afforded comparatively slight protection, being capable of resisting a shrapnel bullet, 41 to the pound, fired to give a striking velocity of 400 ft. per second. The British authorities followed suit and after experiments, in October 1915, produced a helmet of hardened manganese steel weighing 21 oz. and capable of resisting shrapnel at 750 ft. per second. This helmet had the effect of reducing head wounds by 75% of what had formerly been experienced during the war. This gratifying result justified the acceleration of the rate of issue and by July 1916, a million helmets had been delivered to the B.E.F. in France. Later, over a million and a half British made helmets were supplied to the American forces. Helmets of this pattern were also issued to special constables at home for protection against shrapnel from anti-aircraft barrage. The Belgian forces adopted the French pattern. It was not until the summer of 1915 that Germany began to consider the matter of steel helmets, the impetus to the idea being supplied by Professor Friedrich Schwerdt of Hanover. Schwerdt was given a free hand and by the end of 1915 after many experiments had produced a satisfactory helmet, the first of which were used by the shock troops (Stosstruppen) at Verdun in January 1916. They were made from chrome-nickel-steel and weighed approximately 2 lb. 3 oz. The shape was chosen to ensure a maximum ricochet effect with rifle bullets. These steel helmets have become a permanent

part of the soldier's equipment in most armies.

HELMHOLTZ, HERMANN LUDWIG FERDINAND VON (1821-1894), German philosopher and man of science, was born on Aug. 31, 1821, at Potsdam, near Berlin. He lived in Berlin from 1842 to 1849, when he became professor of physiology in Königsberg. There he remained from 1849 to 1855, when he removed to the chair of physiology in Bonn. In 1858 he became professor of physiology in Heidelberg, and in 1871 he occupied the chair of physics in Berlin. To this professorship was added in 1887 the post of director of the physico-technical institute at Charlottenburg, near Berlin, and he held the two positions together until his death on Sept. 8, 1894.

His investigations occupied almost the whole field of science, from physiology to mechanics. In 1847 Helmholtz read to the Physical Society of Berlin a famous paper, *Über die Erhaltung der Kraft* (on the conservation of force), which became one of the epoch-making papers of the century; indeed, along with J. R. Mayer, J. P. Joule and W. Thomson (Lord Kelvin), he may be regarded as one of the founders of the law of the conservation of energy. In 1851, he invented the ophthalmoscope.

Helmholtz's contributions to physiological optics are of great importance. He investigated the optical constants of the eye, measured by his invention, the ophthalmometer, the radii of curvature of the crystalline lens for near and far vision, explained the mechanism of accommodation by which the eye can focus within certain limits, discussed the phenomena of colour vision, and gave a luminous account of the movements of the eyeballs so as to secure single vision with two eyes. In particular he revived and gave new force to the theory of colour-vision associated with the name of Thomas Young, showing the three primary colours to be red, green and violet, and he applied the theory to the explanation of colour-blindness. His great work on *Physiological Optics* (1856-66) is by far the most important book that has appeared on the physiology and physics of vision. Equally distinguished were his labours in physiological acoustics. He explained accurately the mechanism of the bones of the ear, and he discussed the action of the cochlea on the principles of sympathetic vibration.

Perhaps his greatest contribution, however, was his attempt to account for our perception of quality of tone. He showed, both by analysis and by synthesis, that quality depends on the order, number and intensity of the overtones or harmonics that may, and usually do, enter into the structure of a musical tone. He also developed the theory of differential and of summational tones. His work on *Sensations of Tone* (1862) may well be termed the *principia* of physiological acoustics. He may also be said to be the founder of the fixed-pitch theory of vowel tones, according to which it is asserted that the pitch of a vowel depends on the resonance of the mouth, according to the form of the cavity while singing it, and this independently of the pitch of the note on which the vowel is sung. For the later years of his life his labours may be summed up under the following heads: (1) On the conservation of energy; (2) on hydro-dynamics; (3) on electro-dynamics and theories of electricity; (4) on meteorological physics; (5) on optics; and (6) on the abstract principles of dynamics. In all these fields of labour he made important contributions to science, and showed himself equally great in all.

Helmholtz continued his study of the phenomena of electrical oscillations from 1869 to 1871, and in the latter year he announced that the velocity of the propagation of electromagnetic induction was greater than 314,000 metres per second. This work is interesting in view of the fact that Hertz was a pupil of Helmholtz at this time and that later he demonstrated the existence of electromagnetic waves while studying a problem suggested to him by Helmholtz. This was followed by a series of papers on electro-dynamics which were published from 1870 onwards. Helmholtz started with a formula due to F. E. Neuman for the potential of two current elements, and investigated the terms which must be added to give a general expression which agreed with the phenomena of closed circuits. There followed a controversy on the relative merits of the work of Helmholtz, Weber and Clerk Maxwell on this problem. In his paper on the "equations of motion of electricity in conductors at rest" (1874), Helmholtz

applied his generalized formula to the propagation of electric and magnetic disturbances through bodies capable of electric or magnetic polarization. He contributed papers on the theory of the electrical double layer and on electrolysis. Towards the end of his life he wrote on the physical meaning of the Principle of Least Action and applied the principle to electrodynamics. Helmholtz also wrote and lectured on philosophical and aesthetic problems. His position was that of an empiricist, denying the doctrine of innate ideas and holding that all knowledge is founded on experience, hereditarily transmitted or acquired.

See Engelmann, *Gedächtnissrede auf Hermann von Helmholtz* (1894); Königsberger, *Hermann von Helmholtz* (1902; Eng. trans. by F. A. Welby, 1906); J. G. McKendrick, *H. L. F. von Helmholtz* (1899).

HELMINTHOLOGY, the study of parasitic worms. See PLATYHELMINTHES, TREMATODES, TAPEWORMS, NEMATODA, PARASITOLOGY.

HELMOLD, an historian of the 12th century, was a priest at Bosau near Plön. He was a friend of the two bishops of Oldenburg, Vicelin (d. 1154) and Gerold (d. 1163), who did much to Christianize the Slavs. At Bishop Gerold's instigation Helmholtz wrote his *Chronica Slavorum*, a history of the conquest and conversion of the Slavonic countries from the time of Charlemagne. For the life and times of Henry the Lion, duke of Saxony, Helmholtz's chronicle, as that of a contemporary who had exceptional means for gaining information, is of first-rate importance. The history was continued down to 1209 by Abbot Arnold of Lübeck.

The *Chronica* were first edited by Siegmund Schorkel (Frankfurt a. M., 1856). The best edition is by J. M. Lappenberg in *Mon. Germ. hist. scriptores*, xxi. (1869). For critical works on the *Chronica* see A. Potthast, *Bibliotheca hist. med. aevi*, s. "Helmoldus."

HELMOND, town in the province of North Brabant, Holland, on the river Aa, and on the canal Zuid-Willems Vaart between 'sHertogenbosch and Maastricht, 24½ m. by rail W.N.W. of Venlo. It is connected by tramway with 'sHertogenbosch (21 m. N.W.). Pop. (1926) 22,924. The castle of Helmond, built in 1402, is a beautiful specimen of architecture. Helmond is one of the industrial centres of the province, and possesses over a score of factories for textiles, iron founding, soap boiling and tobacco dressing, as well as engine works and a margarine factory.

HELMONT, JEAN BAPTISTE VAN (1577-1644), Belgian chemist, physiologist and physician, was born at Brussels in 1577. (An alternative date for his birth is 1579 and for his death 1635; see *Bull. Roy. Acad. Belg.*, 1907.) He was educated at Louvain, and, after ranging from one science to another, turned to medicine, in which he took his doctor's degree in 1599. In 1609 he settled at Vilvorde, near Brussels, where he occupied himself with chemical experiments and medical practice until his death on Dec. 30, 1644.

Van Helmont presents curious contradictions. On the one hand he was a mystic with strong leanings to the supernatural, an alchemist who believed in the philosopher's stone; on the other hand he was touched with the new learning of Harvey, Galileo and Bacon, and was a careful observer and an exact experimenter. He was the first to understand that there are gases distinct in kind from atmospheric air. The very word "gas" he claims as his own invention, and he perceived that his "gas sylvestre" (carbon dioxide) given off by burning charcoal is the same as that produced by fermenting must. Van Helmont believed that water was the chief, if not the only ultimate constituent of all matter. He showed that plants could grow even though they received nothing but pure water, and so he argued that the wood, bark and roots had been formed from water alone. Van Helmont considered that digestion, nutrition and even movement are due to ferments, which convert dead food into living flesh in six stages. But having got so far with the application of chemical principles to physiological problems, he introduces a complicated system of supernatural agencies like the *archei* of Paracelsus, which preside over and direct the affairs of the body. At the same time chemical principles guided him in the choice of medicines—undue acidity of the digestive juices, for example, was to be corrected by alkalies and *vice versa*; he was thus a forerunner of the iatrochemical school.

His works were collected and published at Amsterdam as *Ortus*

medicinae, vel opera et opuscula omnia in 1668 by his son Franz Mercurius (b. 1618 at Vilvorde, d. 1699 at Berlin), in whose own writings, e.g., *Cabbalah Denudata* (1677) and *Opuscula philosophica* (1690), mystical theosophy and alchemy appear in still wilder confusion.

See also M. Foster, *Lectures on the History of Physiology* (1901); also Chevreul in *Journ. des savants* (Feb. and March 1850), and Cap in *Journ. pharm. chim.* (1852). Other authorities are Poulitier d'Elmoth, *Mémoire sur J. B. van Helmont* (1817); Rixner and Sieber, *Beiträge zur Geschichte der Physiologie* (1819-26), vol. ii.; Spiers, *Helmont's System der Medicin* (1840); Melsens, *Leçons sur van Helmont* (1848); Rommelaere, *Études sur J. B. van Helmont* (1860).

HELMSTEDT, or more rarely Helmstädt, a town of Germany, in the republic of Brunswick, 30 m. W.N.W. of Magdeburg on the main line of railway to Brunswick. Pop. (1925) 17,166. Helmstedt was probably founded about 900, and obtained civic rights in 1099. In 1457 it joined the Hanseatic League, and in 1490 it came into the possession of Brunswick. In 1576 Julius, duke of Brunswick, founded a university here, and throughout the 17th century this was one of the chief seats of Protestant learning. It was closed by Jerome, king of Westphalia, in 1809. The principal buildings are the Juleum, the former university, in Renaissance style (late 16th cent.) and the Stephanskirche dating from the 12th century. The principal manufactures are furniture, yarn, soap, tobacco, machinery, glass and earthenware.

HELMUND, a river of Afghanistan, about 600 m. long, the ancient Etymander, the most important river in Afghanistan, next to the Kabul river, which it exceeds both in volume and length. It rises in the recesses of the Koh-i-Baba to the west of Kabul, its infant stream parting the Unai pass from the Irak, the two chief passes on the well-known road from Kabul to Bamian. About the parallel of 33° N. it enters the Zamindawar province which lies to the north-west of Kandahar, and thenceforward it is a well-mapped river to its termination in the lake of Seistan. Till about 40 m. above Girishk the character of the Helmund is that of a mountain river, flowing through valleys which in summer are the resort of pastoral tribes. On leaving the hills it enters on a flat country, and extends over a gravelly bed. Here also it begins to be used in irrigation. At Girishk it is crossed by the principal route from Herat to Kandahar. Forty-five miles below Girishk the Helmund receives its greatest tributary, the Arghandab, from the high Ghilzai country beyond Kandahar, and becomes a very considerable river, with a width of 300 or 400 yd. and an occasional depth of 9 to 12 ft. Even in the dry season it is never without a plentiful supply of water. The course of the river is more or less south-west from its source till in Seistan it crosses meridian 62°, when it turns nearly north, and so flows for 70 or 80 m. till it falls into the Seistan hamuns, or swamps, by various mouths. In this latter part of its course it forms the boundary between Afghan and Persian Seistan, and owing to constant changes in its bed and the swampy nature of its borders it has been a fertile source of frontier squabbles. Persian Seistan was once highly cultivated by means of a great system of canal irrigation; but, since the country was devastated by Timur, it has been a barren, treeless waste of flat alluvial plain. In years of exceptional flood the Seistan lakes spread southwards into an overflow channel called the Shelag which, running parallel to the northern course of the Helmund in the opposite direction, finally loses its waters in the Gaod-i-Zirreh swamp. Throughout its course from its confluence with the Arghandab to the ford of Chahar Burjak, where it bends northward, the Helmund valley is a narrow green belt of fertility sunk in the midst of a wide alluvial desert, with many thriving villages interspersed amongst the remains of ancient cities, relics of Kaiani rule.

HELM WIND, a violent, cold, easterly wind occasionally blowing down the western slope of Cross Fell, Cumberland, England, when a helm (helmet) cloud covers the summit.

HELOTS (Gr. ἑλωτες or ἑλωται), the serfs of the ancient Spartans. They were probably the aborigines of Laconia who had been enslaved by the Achaeans before the Dorian conquest. After the second Messenian war (see SPARTA), the conquered Messenians were reduced to the status of helots. The helots were State slaves bound to the soil and assigned to individual Spartiates to till their holdings (Gr. κλήροι); their masters could neither emancipate them nor sell them off the land, nor raise the

rent payable yearly in kind by the helots. In time of war, they served as light-armed troops or as rowers in the fleet; from the Peloponnesian war onwards they were occasionally employed as heavy infantry (Gr. *khoplitai*), distinguished bravery being rewarded by emancipation. The general attitude of the Spartans towards them was one of distrust and cruelty. The ephors of each year, on entering office, declared war on the helots so that they might be put to death at any time without violating religious scruple, and we have a well-attested record of 2,000 helots being freed for service in war and then secretly assassinated. (Thuc. iv. 80.) (See *CRYPTeia*.)

Intermediate between Helots and Spartiates were the *Neodamodes* and *Mothones*. The former were emancipated helots, or their descendants, and were much used in war; they served especially on foreign campaigns, as that of Agesilaus (396–394 B.C.) in Asia Minor. The *mothones*, or *mothakes*, were the sons of Spartiates and helot mothers; they were free men sharing the Spartan training, but not full citizens.

See C. O. Müller, *History and Antiquities of the Doric Race* (Eng. trans.), bk. iii. ch. 3.; G. Gilbert, *Greek Constitutional Antiquities* (Eng. trans. 1895); A. H. J. Greenidge, *Handbook of Greek Constitutional History* (1896); A. Whibley, *Companion to Greek Studies* (1923).

HELPS, SIR ARTHUR (1813–1875), English writer and clerk of the privy council, son of a London merchant, was educated at Eton and at Trinity college, Cambridge. In 1860 he was appointed clerk of the privy council, on the recommendation of Lord Granville.

His appointment as clerk of the council brought him into personal communication with Queen Victoria and the Prince Consort, both of whom came to regard him with confidence and respect. After the prince's death, the queen asked Helps to prepare the appreciation of her husband's life and character contained in his introduction to the collection (1862) of the Prince Consort's speeches and addresses. He edited and wrote a preface to the *Queen's Leaves from a Journal of our Life in the Highlands* (1868). He died on March 7, 1875.

Helps's other works include *Friends in Council, a Series of Readings and Discourse thereon* (1847–59); *The Conquerors of the New World and their Bondsmen* (2 vols., 1848–52); and *The Spanish Conquest in America, and its Relation to the History of Slavery and the Government of Colonies* (4 vols., 1855–57–61).

HELSEINGBORG, a seaport of Sweden in the district (*län*) of Malmöhus, 35 m. N. by E. of Copenhagen by rail and water. Pop. (1928) 53,417. The original site of the town is marked by the tower of the old fortress, which is first mentioned in 1135 and whose ruins stand on a hill above the town. From 1370 along with other towns in the province of Skåne, it was united for 15 years with the Hanseatic League. The fortress was destroyed by fire in 1418, and about 1425 Eric XIII. built another near the sea, and caused the town to be transported thither, bestowing upon it important privileges. Until 1658 it belonged to Denmark, and in 1684 its fortifications were dismantled. It was re-taken by the Danes several times but in 1710 the town came finally into the possession of Sweden. It stands on the narrowest part of Öresund (the Sound), here only 3 m. wide, opposite Helsingör (Elsinore) in Denmark. On the outskirts are the Öresund park containing iodide and bromide springs, and sea-baths. On the coast to the north is the royal *château* of Sofiero; to the south, the small spa of Ramlösa. North and east of Helsingborg lies the only coal-field in Sweden, extending into the Kullen peninsula. Potter's clay is also found. Helsingborg ranks among the first manufacturing towns of Sweden, having copper works, using ore from Sulitelma in Norway, india-rubber works, sugar refineries, super-phosphate works and breweries. The new harbour has a depth of 32 ft., and there are extensive docks. The chief exports are timber, dairy produce, paper, rubber wares and iron ore.

HELSEINGFORS or **HELSEINKI**, the capital, seaport and only large town of the republic of Finland. In 1810 it had only 4,065 inhabitants; in 1926 there were 215,829. Helsinki is well laid out with wide streets, parks and gardens. The principal square contains the cathedral of St. Nicholas, the Senate house

and the university, all striking buildings of architectural distinction. They are mainly classical in style, but a number of modern buildings show the national spirit by using local material and decorative skill. Other public institutions are the Athenaeum, with picture gallery, a Swedish theatre and opera house, a Finnish theatre and the Archives. Some of the scientific societies have a wide reputation, and great interest and foresight is shown in educational matters. The use of the Finnish language for educational purposes has become general, but Western languages, French and English, and to some extent German, are also employed along with Swedish, the old language of culture in the country.

The fine harbour is divided into two parts by a promontory, and is protected at its entrance by a group of small islands. A third harbour is situated on the west side of the promontory, and all three have granite quays. The harbour accommodates the largest vessels, but it is usually closed by ice from January to the end of April, except for a channel kept open by an ice breaker. The harbour has been much improved in recent years and had over 7,000 yd. of quay in 1924. In 1925 a coal wharf was erected and a goods station was built alongside the harbour. Helsinki imports coal, machinery, sugar, grain and clothing. The manufactures of the city consist largely of tobacco, beer and spirits, and carpets.

HELST, BARTHOLOMAEUS VAN DER (1613–1670), Dutch painter, born at Haarlem, and died at Amsterdam. He was the son of Lodenyk Lowys v. d. Helst, merchant and innkeeper. The artist is first mentioned in 1636 when he married Anna du Pire at Amsterdam. He was a pupil of Nicolas Elias. His first great picture is the portrait group of the regents of the almshouse of Amsterdam, dated 1637. Then follow two groups of civic guards dated 1643 and 1648 in the gallery at Amsterdam. Here too are the noble portraits of the burgomaster Bicker and Andreas Bicker the younger, completed in 1642. The portrait of Bicker's wife is in the Dresden gallery. He produced little or nothing besides portraits at any time, but founded, in conjunction with Nicolaes de Helt Stokade, the painters' guild at Amsterdam in 1653. His likeness of Paul Potter at the Hague was executed in 1654.

His great work, "The Peace of Münster" (1648), in the gallery of Amsterdam challenges comparison at once with the so-called "Night Watch" by Rembrandt. But, great as the qualities of van der Helst undoubtedly are, he remains below the line of demarcation which separates the second from the first-rate masters of art.

His pictures number about 100. At Amsterdam the four regents in the Werkhuys (1650), four syndics in the gallery (1656), and four syndics in the town hall (1657) are masterpieces, to which may be added a number of fine single portraits. Rotterdam, notwithstanding the fire of 1864, still boasts of five of van der Helst's works. The Hague owns four. Leningrad, on the other hand, possesses ten. The Louvre has four, Munich three. Other pieces are in the galleries of Berlin, Brunswick, Brussels, Carlsruhe, Cassel, Darmstadt, Dresden, Frankfurt, Gotha, London, New York, Schwerin, Utrecht and Vienna. See J. J. Gelder, *Barth. van der Helst* (1921).

HELSTON, a market town and municipal borough of Cornwall, England, 11 m. W.S.W. of Falmouth. Pop. (1921) 2,616.

Helston (Henliston, Haliston, Helleston), the capital of the Meneage district of Cornwall, was held by Earl Harold in the time of the Confessor and by King William at the Domesday Survey. In 1585 Elizabeth granted a charter of incorporation, which was confirmed in 1641. From 1294 to 1832 Helston returned two members to parliament. In 1774 the number of electors (which by usage had been restricted to the mayor, aldermen and freemen elected by them) had dwindled to six, and in 1790 to one person only.

The town is situated on the river Cober, which expands into Looe Pool, the water being banked up by Looe Bar at the mouth. The mining industry on which the town formerly depended is extinct, but the district is agricultural and dairy farming is carried on. Helston is the nearest railway station to the Lizard, and there is a considerable tourist traffic in summer. Some trade passes through the small port of Porthleven, 3 m. south-west. A holiday held on May 8 (Flora day) was marked by floral decorations and the chanting of folk songs. Attempts have been made to revive it in recent years.

HELVETIC CONFESSIONS, the name of two documents expressing the common belief of the reformed churches of Switzerland. The first, known also as the Second Confession of Basel, was drawn up at that city in 1536 by Henry Bullinger and others. The Second Helvetic Confession was written by Bullinger in 1562 and revised in 1564 as a private exercise. It came to the notice of the elector palatine Friedrich III., who had it translated into German and published. It gained a favourable hold on the Swiss churches, who had found the First Confession too short and too Lutheran. It was adopted by the Reformed Church not only throughout Switzerland but in Scotland (1566), Hungary (1567), France (1571), Poland (1578), and next to the Heidelberg Catechism (*q.v.*) is the most generally recognized Confession of the Reformed Church.

See L. Thomas, *La Confession helvétique* (Geneva, 1833); P. Schaff, *Credentials of Christendom*, i. 390-420, iii. 234-306; Müller, *Die Bekenntnisschriften der reformierten Kirche* (Leipzig, 1903); W. A. Curtis, art. "Confessions," in Hastings, *Encyclopaedia of Religion and Ethics*, vol. iii. p. 860-61.

HELVETII, a Celtic people, whose original home was situated in the country between the Hercynian forest, the Rhine, and the Main. In Caesar's time their boundaries were the Jura on the W., the Rhone and the lake of Geneva on the S., the Rhine as far as Lake Constance on the N. and E. They thus inhabited the western part of modern Switzerland. They were divided into four cantons (*pagi*), common affairs being managed by the cantonal assemblies. They possessed the elements of a higher civilization (gold coinage and the Greek alphabet), and, according to Caesar, were the bravest people of Gaul. The reports of gold and plunder spread by the Cimbri and Teutones (*qq.v.*) on their way to southern Gaul induced the Helvetii to follow their example. In 107 B.C., two of their tribes, the Tougeni and Tigurini, crossed the Jura and defeated the Romans under L. Cassius Longinus. In 102 B.C., the Helvetii joined the Cimbri in the invasion of Italy, but after the defeat of the latter by Marius they returned home. In 58 B.C., hard pressed by the Germans and incited by one of their princes, Orgetorix, they resolved to found a new home west of the Jura. Joined by the Rauraci, Tulingi, Latobrigi, and some of the Boii they agreed to meet at Geneva and to advance through the territory of the Allobroges. They were overtaken by Caesar at Bibracte, defeated and forced to submit.

Under Augustus, Helvetia (*ager Helvetiorum*) proper was included under Gallia Belgica. Two Roman colonies were founded at Noviodunum (*Nyon*) and at Augusta Rauracorum (*Augst* near Basel) to keep watch over the inhabitants, who were treated with generosity by their conquerors. Under the name of *foederati* they retained their original constitution and division into four cantons. They were under an obligation to furnish a contingent to the Roman army for foreign service, but were allowed to maintain garrisons of their own, and their magistrates had the right to call out a militia; they managed their own local affairs and kept their own language, although Latin was used officially. Their chief towns were Aventicum (*Avenches*) and Vindonissa (*Windisch*). Under Tiberius, the Helvetii were separated from Gallia Belgica and made part of Germania Superior. After the death of Galba (A.D. 69), as they refused submission to Vitellius their land was devastated by Alienus Caecina. Under Vespasian, they attained the height of their prosperity. He greatly increased the importance of Aventicum, where his father had carried on business. Its inhabitants obtained the *ius Latinum*, had a council of *decuriones*, flamens of Augustus, etc. (see *MUNICIPALITY*). After the extension of the eastern frontier, the troops were withdrawn, and Helvetia became completely romanized. Aventicum had an amphitheatre, a public gymnasium, and an academy with Roman professors. Roads were made wherever possible, and commerce rapidly developed. The west of the country was more susceptible to Roman influence, and hence preserved its independence against barbarian invaders longer than its eastern portion. During the reign of Gallienus (A.D. 260-268) the Alamanni overran the country and it never regained its former prosperity. Under Honorius (A.D. 395-423) it was occupied by the Alamanni, except in

the west, where the small portion remaining to the Romans was ceded in A.D. 436 by Aetius to the Burgundians.

HELVÉTIUS, CLAUDE ADRIEN (1715-1771), French philosopher and littérateur, was born in Paris in Jan. 1715, the son of the chief physician to Queen Marie Leczinska of France. In 1738, at the queen's request, he was appointed farmer-general, a post of great responsibility and dignity. He proceeded to enjoy his leisure, producing a poem, *Le Bonheur* (published posthumously, with an account of Helvétius's life and works, by C. F. de Saint-Lambert, 1773), in which he develops the idea that true happiness is only to be found in making the interest of one that of all, and his famous philosophical study, *De l'esprit* (1758, Eng. trans. by W. Mudford, 1807), intended to be the rival of Montesquieu's *L'Esprit des lois*. This attracted immediate attention and aroused the most formidable opposition, especially from the dauphin, son of Louis XV. The Sorbonne condemned it as full of the most dangerous doctrines, and the author's three separate retractations did not save it from being publicly burnt. Voltaire said that it was full of commonplaces, and that what was original was false or problematical; Rousseau declared that the very benevolence of the author gave the lie to his principles. In 1764 Helvétius visited England, and the next year, on the invitation of Frederick II., went to Berlin. He then passed the remainder of his life quietly on his country estate in France. He died on Dec. 26, 1771.

The three chief contentions in Helvétius's crudely hedonistic work are: (1) All man's faculties may be reduced to physical sensation, even memory, comparison, judgment. (2) Self-interest, founded on the love of pleasure and the fear of pain, is the spring of judgment, action, affection; self-sacrifice is prompted by the fact that the sensation of pleasure outweighs the accompanying pain; it is thus the result of deliberate calculation; we have no liberty of choice between good and evil; there is no such thing as absolute right—ideas of justice and injustice change according to customs. (3) All intellects are equal; their apparent inequalities are due to the unequal desire for instruction, and this desire springs from passions, of which all men commonly well organized are susceptible to the same degree; and we can, therefore, all love glory with the same enthusiasm and we owe all to education.

De l'homme, de ses facultés intellectuelles et de son éducation (1773, Eng. trans. by W. Hooper, 1777), a supplement to *De l'esprit*, is a polemic against the distinction between private and public interests. A complete edition of the works of Helvétius was published at Paris, 1818. See V. Cousin, *Philosophie Sensualiste* (1863); D. G. Mostratos, *Die Pädagogik des Helvétius* (1891); A. Guillois, *Le Salon de Madame Helvétius* (1894); A. Piazza, *Le Idee filosofiche specialmente pedagogiche di C. A. Helvétius* (Milan, 1889); G. Plekhanov, *Beiträge zur Geschichte des Materialismus* (Stuttgart, 1896); L. Limentani, *Le Teorie psicologiche di Helvétius* (Verona, 1902); A. Keim, *Helvétius, sa vie et son oeuvre* (1907); J. B. Séverac, *Helvétius*, in *Les Grands Philosophes* series (1910).

HELVIDIUS PRISCUS, Stoic philosopher and statesman, lived during the reigns of Nero, Galba, Otho, Vitellius and Vespasian. He held high offices during this time, in spite of his republican views. During Nero's reign he was quaestor of Achaëa and tribune of the plebs (A.D. 56), and restored order in Armenia. His declared sympathy with Brutus and Cassius occasioned his banishment in 66. Having been recalled to Rome by Galba in 68, he at once impeached Eprius Marcellus, the accuser of Thræsa Paetus, but dropped the charge, as the condemnation of Marcellus would have involved a number of senators. As praetor elect he ventured to oppose Vitellius in the senate (Tacitus, *Hist.* ii. 91), and as praetor (70) he maintained, in opposition to Vespasian, that the management of the finances ought to be left to the discretion of the senate; he proposed that the capitol, which had been destroyed in the Neronian conflagration, should be

restored at the public expense; he saluted Vespasian by his private name, and did not recognize him as emperor in his praetorian edicts. At length he was banished a second time, and shortly afterwards was executed by Vespasian's order.

See Tacitus, *Hist.* iv. 5, *Dialogus*, 5; Dio Cassius lxxvi. 12, lxxvii. 13; Suetonius, *Vespasian*, 15; Pliny, *Epp.* vii. 19.

HELWAN, a well-known health resort in Egypt, 16 m. south of Cairo and connected with it by rail. Standing 150 ft. above the Nile level, and surrounded by desert, it enjoys a dry equable climate specially suitable for invalids; and it possesses strong sulphur and salt springs with a natural temperature of 91° F. The Egyptian government opened a fully equipped thermal establishment in 1900, and the station has been provided with hotels and all the usual forms of amusement familiar at European spas. An astronomical observatory was built here in 1903-04, to replace the former observatory at Abbasia. On the opposite bank of the river lie the ruins of Memphis and the famous pyramids of Sakkara.

HELY-HUTCHINSON, JOHN (1724-1794), Irish lawyer, statesman, and provost of Trinity college, Dublin, son of Francis Hely, a gentleman of County Cork, was educated at Trinity college, Dublin, and was called to the Irish bar in 1748. He took the additional name of Hutchinson on his marriage in 1751. He entered the Irish House of Commons in 1759, but joining the "patriotic" party in opposition to the Government, and although he afterwards joined the administration he never abandoned his advocacy of popular measures.

For his support of the Augmentation bill (for an increase in the army establishment in Ireland) carried in the session of 1769, Hely-Hutchinson received an addition of £1,000 a year to the salary of his sinecure of Alnagar, a major's commission in a cavalry regiment, and a promise of the secretaryship of State. He was at this time one of the most brilliant debaters in the Irish parliament, and he was enjoying an exceedingly lucrative practice at the bar, which, with his sinecure, he sacrificed in 1774 to become provost of Trinity college, Dublin.

In the Irish House he advocated free trade, the relief of the Catholics from penal legislation, and the reform of parliament. He was one of the very earliest politicians to recognize the soundness of Adam Smith's views on trade; and he quoted from the *Wealth of Nations*, adopting some of its principles, in his *Commercial Restraints of Ireland*, published in 1779, which Lecky pronounces "one of the best specimens of political literature produced in Ireland in the latter half of the 18th century." Hely-Hutchinson's remarkably able state paper on the economic condition of Ireland (ms. in the Record Office, London), showed clear traces of the influence of Adam Smith. Not less enlightened were his views on the Catholic question.

In 1777 Hely-Hutchinson became secretary of State. When Grattan in 1782 moved an address to the king containing a declaration of Irish legislative independence, Hely-Hutchinson supported the attorney-general's motion postponing the question; but on April 16, after the Easter recess, he read a message from the lord lieutenant, the duke of Portland, giving the king's permission for the House to take the matter into consideration, and he expressed his personal sympathy with the popular cause which Grattan on the same day brought to a triumphant issue (see GRATTAN, HENRY). Hely-Hutchinson supported the opposition on the regency question in 1788, and one of his last votes in the House was in favour of parliamentary reform. He died at Buxton on Sept. 4, 1794.

In 1785 his wife had been created Baroness Donoughmore and on her death in 1788, his eldest son Richard (1756-1825) succeeded to the title.

See W. E. H. Lecky, *Hist. of Ireland in the Eighteenth Century* (5 vols., 1892); J. A. Froude, *The English in Ireland in the Eighteenth Century* (3 vols., 1872-74); H. Grattan, *Memoirs of the Life and Times of Henry Grattan* (8 vols., 1839-46); *Baratariana*, by various writers (Dublin, 1773).

HELYOT, PIERRE (1660-1716), Franciscan friar and historian, was born at Paris in Jan. 1660, and in 1683 entered the third order of St. Francis at Picpus, near Paris. During his travels to many parts of Europe on monastic business he collected

materials for his great work, *L'Histoire des ordres monastiques, religieux, et militaires, et des congrégations séculières* (8 vols., 1714-21). Helyot died on Jan. 5, 1716, before the fifth volume appeared, but his friend Maximilien Bullot completed the edition. The *Histoire* is a work of great historical importance, and is profusely illustrated by plates exhibiting the dress of the various orders. The material has been arranged in dictionary form in Migne's *Encyclopédie théologique*, under the title "Dictionnaire des ordres religieux" (4 vols., 1858). Helyot's only other noteworthy work is *Le Chrétien mourant* (1695).

HEMANS, FELICIA DOROTHEA (1793-1835), English poetess, was born in Duke street, Liverpool, on Sept. 25, 1793, the daughter of George Browne, a Liverpool merchant of Irish extraction. Her mother seems to have been of Austrian origin. In 1806 the family moved to Gwrych, Denbighshire, and there Felicia grew up by the Welsh mountains and the sea-shore. When she was only 14, her *Juvenile Poems* were published by subscription, and were harshly criticized in the *Monthly Review*. Her *Domestic Affections and other Poems* appeared in 1812, on the eve of her marriage to Capt. Alfred Hemans, adjutant of the Northamptonshire Militia. While they lived at Bronwyllfa, a house near St. Asaph, she published *The Restoration of Works of Art to Italy* (1816), *Modern Greece* (1817), and *Translations from Camoens and other Poets* (1818). Husband and wife separated in 1818, and though letters were interchanged concerning their five children, they never met again. Her next productions were *Tales and Historic Scenes in Verse* (1819), *The Sceptic and Stanzas to the Memory of the late King* (1820), a volume of poems containing "The Siege of Valencia," "The Last Constantine," and "Belshazzar's Feast" (1823), and *The Forest Sanctuary and Lays of Many Lands* (1825), which were two of her favourite works.

In 1828, Mrs. Hemans moved to Wavertree, near Liverpool. In the following summer she visited the Hamiltons of Chiefswood, where she enjoyed "constant, almost daily, intercourse" with Sir Walter Scott, who had written an epilogue for her play, *The Vespers of Palermo*, produced at Edinburgh in April 1824. It had been acted at Covent Garden on Dec. 12, 1823, but was withdrawn after the first performance. In 1830 she visited Wordsworth and the Lake country, and went again to Scotland. Her publications of this period include *Songs of the Affections* (1830), *Hymns for Childhood* (1834; had appeared in America in 1827), *National Lyrics* (1834), *Scenes and Hymns of Life* (1834), and a series of sonnets, *Thoughts during Sickness*. She died in Dublin on May 16, 1835.

Mrs. Hemans's poetry is the outcome of a beautiful but singularly circumscribed life, a life spent in romantic seclusion, without much worldly experience, and warped by domestic unhappiness and physical suffering. Scott complained that it contained "too many flowers" and "too little fruit." Her reputation rests on her short poems, such as "The Treasures of the Deep," "The Better Land," "The Homes of England," "Casabianca," "The Palm Tree," "The Graves of a Household," "The Wreck," "The Dying Improvisatore," "The Lost Pleiad," and the "Landing of the Pilgrims," beginning:

The breaking waves dashed high on a stern and rock bound coast.

Mrs. Hemans's *Poetical Works* were collected in 1832 (last ed., Oxford, 1914); her *Memorials*, etc., by H. F. Chorley (1836).

HEMEL HEMPSTEAD, a town and municipal borough in Hertfordshire, England, 25 m. N.W. from London. Pop. (1921) 13,826. Settlements in the neighbourhood of Hemel Hempstead (*Hamalamstede*, *Hemel Hampsted*) date from pre-Roman times, and a Roman villa has been discovered at Boxmoor. The manor, royal demesne in 1086, was granted by Edmund Plantagenet in 1285 to the house of Ashridge, and the town developed under monastic protection. In 1539 a charter incorporated the bailiff and inhabitants. A mayor, aldermen and councillors received governing power by a charter of 1898. It is situated in the Gade valley, near the Grand Junction canal. The church of St. Mary is a Norman building with Decorated additions. Industries include the manufacture of paper and iron founding.

HEMEROBAPTISTS: see ESSENES.

HEMICHORDA or **HEMICHORDATA**, a zoological term introduced by W. Bateson in 1884 as equivalent to Enteropneusta, which then included the single genus *Balanoglossus*, and now generally employed to cover a group of marine worm-like animals probably related to the lower vertebrates. Vertebrates, or Chordates, are distinguished by the presence of a notochord, which forms the longitudinal axis of the body; by the gill-slits in the pharynx; and by the hollow dorsal central nervous system (see VERTEBRATA). In the Hemichorda, the respiratory organs closely resemble gill-slits, and structures comparable with the notochord and the tubular dorsal nervous system are present.

The Hemichorda include two orders, the Pterobranchia (*q.v.*) and the Enteropneusta (see *BALANOGLOSSUS*), and are now generally regarded as a sub-phylum of the Chordata.

HEMICYCLE, in architecture, any large, semi-circular recess, usually covered with a semi-dome; a monumental exedra (*q.v.*).

HEMIMORPHITE, a mineral consisting of hydrous zinc silicate, $H_2Zn_2SiO_5$, of importance as an ore of the metal, of which it contains 54.4%. It is interesting crystallographically by reason of the hemimorphic development of its orthorhombic crystals; these are prismatic in habit and are differently terminated at the two ends. Connected with this polarity of the crystals is their pyroelectric character—when a crystal is subjected to changes of temperature it becomes positively electrified at one end and negatively at the other. There are perfect cleavages parallel to the prism faces. Crystals are usually colourless, sometimes yellowish or greenish, and transparent; they have vitreous lustre. The hardness is 5, and the specific gravity 3.45. The mineral also occurs as stalactitic or botryoidal masses with a fibrous structure, or in a massive, cellular or granular condition intermixed with calamine and clay. It is decomposed by hydrochloric acid with gelatinization; this property affords a ready means of distinguishing hemimorphite from calamine (zinc carbonate), these two minerals being, when not crystallized, very like each other in appearance.

Hemimorphite occurs with other ores of zinc (calamine and blende), forming veins and beds in sedimentary limestones. British localities are Matlock, Alston, Mendip hills and Leadhills; at Roughen Gill, Caldbeck Fells, Cumberland, it occurs as mammillated sky-blue incrustations. Well-crystallized specimens have been found in the zinc mines at Altenberg (Vieille-Montagne) in Belgium, Nerchinsk, Siberia and Elkhorn, Montana.

HEMINGBURGH, WALTER OF, also commonly, but erroneously, called Walter Hemingford, a Latin chronicler of the 14th century, was a canon regular of the Austin priory of Gisburn in Yorkshire. Hence he is sometimes known as Walter of Gisburn (*Walterus Gisburnensis*). Bale seems to have been the first to give him the name by which he became more commonly known. His chronicle embraces the period of English history from the Conquest (1066) to the nineteenth year of Edward III., with the exception of the years 1316–26. In compiling the first part, Hemingburgh apparently used the histories of Eadmer, Hoveden, Henry of Huntingdon, and William of Newburgh; but the reigns of the three Edwards are original, composed from personal observation and information. There are several manuscripts of the history extant—the best perhaps being that presented to the College of Arms by the earl of Arundel.

The first three books were published by Thomas Gale in 1687, in his *Historiae Anglicanae scriptores quinque*, and the remainder by Thomas Hearne in 1731. The first portion was again published in 1848 by the English Historical Society, under the title *Chronicon Walteri de Hemingburgh, vulgo Hemingford nuncupati, de gestis regum Angliae*, edited by H. C. Hamilton.

HEMIPODE, a name given to the bustard-quails, inhabitants of Africa, Southeastern Asia and Australia, which stand between the quails and the rails. Of the 30 species, 29 belong to the genus *Turnix*. They are called hemipodes (half-footed) because the first toe is absent. As among the phalaropes (*q.v.*) the females are larger and more brightly coloured than the males, which perform the duties of incubation and caring for the young.

HEMIPTERA (Gr. *ἡμι* half and *πτερόν* a wing), the name applied in zoological classification to that order of insects (*q.v.*) which includes plant-bugs, cicadas, aphides and scale insects.

The name was first given by Linnaeus (1735) who applied it in allusion to the half-coriaceous and half-membranous character of the fore-wings in many species of the order. This expression, however, is not very well suited as the fore-wings in many members are of a uniform texture, and the most characteristic feature is afforded by the mouth-parts which form a beak-like proboscis with piercing and sucking stylets. This latter feature led J. C. Fabricius (1775) to substitute the name Rhynchota (*Rhynchota*) which is still used by many authorities. Hemiptera number about 36,000 described species; the great majority are plant feeders and rank among the most destructive of all insects. Two pairs of wings are generally present, the anterior pair being most often of harder consistency than the posterior pair, or with the apical region more membranous than the remainder. The mouth-parts are always adapted for sucking and piercing and the palpi are atrophied. Metamorphosis is incomplete (fig. 13) in most cases but, more rarely, complete in certain others (fig. 14). Collectively the members of the order are known as plant-bugs: most of them are of small or moderate size while a few, such as the giant water-bugs and cicadas are very large insects. The prevailing type of colouration is green, but cicadas, lantern flies and their allies, and cotton stainers are often conspicuously coloured.

General Structure.—The head is very variable in form and in most cases the sclerites are compactly fused with few noticeable sutures. As a rule the antennae have only four or five joints but in exceptional cases 10 (*Psyllidae*) or even 25 joints (males of a few *Coccidae*) may be present. The mouth-parts are of an exceptionally uniform character throughout the order, a feature that is correlated with the universal habit of feeding by means of piercing and sucking. The mandibles and maxillae are in the form of needle-like stylets and are intimately held together so as to function almost as one organ (fig. 1). Each maxilla bears

FIG. 1.—DIAGRAM OF MOUTH PARTS AND ADJACENT REGIONS OF HEAD OF HEMIPTERAL INSECT. AT RIGHT ARE TRANSVERSE SECTIONS ACROSS REGIONS BEARING CORRESPONDING LETTERING ON LEFT-HAND FIGURE. (THE MAGNIFICATION OF THESE SECTIONS IS NOT UNIFORM)

two grooves separated by a longitudinal ridge and the two maxillae are locked together so that the grooves form a pair of minute tubes. The upper tube so formed is the suction canal through which the food is imbibed, while the lower tube allows for the flow of the saliva into the plant and is hence termed the ejection canal. The labium takes the form of a jointed sheath or rostrum which is grooved above to form a slot in which the other mouth-parts repose when at rest. The labium takes no part in feeding, and both pairs of palpi are wanting. In many members of the order the pronotum is a large conspicuous shield as in beetles,

the legs have three or fewer joints to the tarsi and the wings are exceedingly variable in character with relatively scanty venation. In the sub-order Heteroptera the forewings are termed hemelytra (hemi-elytra) and their proximal area is horny or leathery, re-

FIG. 2.—DIAGRAM OF THE FORE-WING, OR HEMELYTRON, OF AN HETEROPTEROUS BUG, SHOWING AREAS INTO WHICH IT IS DIVIDED

sembling an elytron, only the distal portion remaining membranous. The hind wings are always membranous and in repose are folded beneath the hemelytra. The hardened basal portion of the hemelytron is divided into a narrow posterior area or clavus and a broader main portion or corium. In some cases a narrow strip of the corium is marked off along the anterior margin to form the embolium and in Capsid bugs there is a triangular apical area to the corium which is termed the cuneus (fig. 2). In the sub-order Homoptera the forewings are of uniform texture and frequently of harder consistency than the hind pair. Many members of the order are wingless, especially in aphides and the females of all scale insects. In other cases there are several degrees of wing development within a single species—wingless, fully-winged and half-winged individuals being present. The meaning of this wing-polymorphism is obscure. The abdomen sometimes exhibits indications of 11 segments, but reduction or suppression of one or more is the rule. In some water-bugs a true ovipositor is well developed but in other groups it is inconspicuous or wanting.

FIG. 3.—TYPICAL SHIELD BUG (*TROPICORIS RUFIPES*) OF THE SUB-ORDER HETEROPTERA

in some cases living on the surface of water. The Pentatomidae or shield bugs are rather large and often brightly coloured insects, characterised by the great size of the scutellum which sometimes covers the abdomen (fig. 3). The Coreidae have a smaller scutellum and the antennae are placed high upon the head: the squash bug (*Anasa tristis*) of the U.S. is a well known example. The

Lygaeidae are related to them, but the antennae are placed lower on the head: the American chinch bug (*Blissus leucopterus*) is well known and the family includes about 50 British species. The Pyrrhocoridae or red bugs differ from Lygaeidae in having no ocelli; most species have bright red, or green, and black coloration and the injurious cotton-stainers (*Dysdercus*) are well known examples. The Tingidae or lacebugs are small creatures, whose integument exhibits a beautiful net-like pattern and the

tarsi are 2-jointed. The Hydrometridae are a large family of pond-skaters which are clothed below with silvery pubescence: the genus *Halobates* and its allies (fig. 4) occur far out on the ocean in warm latitudes. The Reduviidae are a family of over 2,000 species, with a prominently curved rostrum: they mostly live on the blood of other insects, while species of *Triatoma* and *Reduvius* suck the blood of man. The Cimicidae (fig. 5) are the well known bed-bugs (*Cimex*) which are blood-suckers of mammals and birds and the Polyctenidae are curious parasites living on bats. The Capsidae are a large family in which the hemelytra have a cuneus, but no embolium (fig. 6): over 180 species are British and some are serious enemies of fruit trees.

FIG. 6.—CAPSID LEAF-BUG (*POECILOPSUS LINEATUS*) OF NORTH AMERICA. MAGNIFIED

strong oar-like legs and when diving carry a supply of air beneath the wings. They are markedly predaceous and can inflict painful punctures when handled. The Corixidae are numerous in most countries, and are largely bottom-dwellers notable for their faculty of stridulation.

SUB-ORDER II. HOMOPTERA

Wings usually sloping roof-wise over the sides of the body when at rest, the fore-pair of uniform consistency, but wingless forms are frequent. Pronotum small, tarsi 1- to 3-jointed. By far the greater number of the Hemiptera belong to this sub-order and,

Series II. CRYPTOCERATA.—Aquatic species with concealed antennae. Included here are the Belostomatidae or giant water-bugs of the Tropics which may exceed 4in. in length. They feed upon small fish, tadpoles and other insects, but often take to the wing and are attracted to lights at night. The Nepidae or water scorpions (fig. 7) have an apical breathing tube at the extremity of the abdomen, raptorial forelegs and 3-jointed antennae. The Notonectidae or water-boatmen (*q.v.*) swim on their backs by means of their

with the exception of the cicadas and lantern flies, they are mostly small or very small, fragile insects. The Cicadidae or cicadas (*q.v.*) include over 1,000 species of large insects with ample membranous wings and toothed femora to the fore-legs. The males almost always have a sound-producing apparatus on each side of the base of the abdomen (fig. 9) and are very powerful stridulators. The nymphs (fig. 8) live below ground at the roots of plants. The family is mainly tropical: 74 species occur in North America but there is only a single representative in Britain where it is rarely found. The Fulgoroidea are an assemblage of about 13 families, the members of many of which secrete wax in various forms: the best known examples are the large tropical lantern flies which, however, are not luminous. The Membracidae are remarkable on account of the development of the pronotum into variably shaped processes which extend far backward over the body. The Cercopidae comprise the cuckoo spit insects (*q.v.*) or froghoppers and the Jassidae include the leaf-hoppers (fig. 10). Both families are exceedingly large groups of small insects, numerous in Britain and most parts of the world. The Psyllidae or jumping lice include the apple- and pear-suckers and have usually 10-jointed antennae and the fore-wings are of somewhat firmer consistency than the hind pair. The Aphididae (fig. 11) are the large and very important family of aphides (*q.v.*) which include many injurious species and undergo a highly complex life-cycle: among the best known forms are the woolly aphid of the apple and the vine *Phylloxera* (*q.v.*). The Aleurodidae or white flies are minute fragile creatures dusted with a waxy powder: the greenhouse white-fly (*Asterochiton vaporariorum*) is the only species likely to attract notice. The

FIG. 8.—DIAGRAM OF NYMPH OF CICADA, SHOWING LEG STRUCTURE

Coccidae (fig. 12) form one of most noxious groups of all insects and include the scale insects (*q.v.*) and mealy bugs. The females are degenerate wingless insects and cause most of the damage entailed by this family, while the males are very fragile creatures with a single pair of wings and no mouth-parts.

Reproduction and Development.—In most Hemiptera the nymphs resemble the parents except for the absence of wings and they are active through all stages of growth, feeding in a manner similar to the adults. The number of moults undergone is very variable and the wing-rudiments appear among Heteroptera about

the fourth instar (fig. 13). Cicadas are remarkable because the young insects are adapted for burrowing, and suck the sap from roots, while the adults are aerial. In male Coccidae an incipient pupal stage is passed through (fig. 14) and the same occurs in both sexes of Aleurodidae: these families, therefore, afford a transition towards insects with complete metamorphosis. Most Heteroptera in temperate countries appear to be single-brooded, but among Homoptera the rate of reproduction is often extraordinarily rapid, which is an important factor bearing upon the injurious nature of many of the species. The estimates of Réaumur and Huxley regarding the fecundity of parthenogenetic

At upper left the abdomen has been opened from above to show the muscles that vibrate the tympana, and the large air-sac

aphides are well known. Buckton, on the other hand, thinks that they are placed too low and he states that the progeny of a single aphid at the end of 300 days (if all members survived) would be the 15th power of 210! R. C. L. Perkins mentions with regard to leaf-hoppers, that if each hopper lays 50 eggs, and the sexes are about equal in number of individuals, in six generations the progeny of one female would amount at the end of the season to 500,000,000. Fortunately climatic changes, parasites and predators collectively maintain the proper balance of such prolific creatures by destroying them in vast numbers.

Geographical Distribution.

—Although very widely distributed, Hemiptera have not penetrated as far into remote and inhospitable regions as have some of the other orders. The Fulgoroidea and Cicadidae are more especially tropical groups and the Membracidae attain their greatest development in Central and South America, but many of the other large families are well represented in most countries. Some species such as the bed-bug (*Cimex lectularius*) and the shield bug, *Nesara viridula*, are nearly world-wide and a number of European species have found their way into North America.

FROM "MEMOIRS OF THE DEPARTMENT OF AGRICULTURE," AFTER MISRA (HIGH COMMISSIONER FOR INDIA)

FIG. 10.—THE LEAFHOPPER (*NEOPHLEBOTIX APICALIS*)

Geological Distribution.—Hemiptera first appear in geological times in Lower Permian rocks of Kansas and Germany. The remarkable German fossil *Eugeron* has the typical Hemipterous mouth-parts except that the labium is paired and unfused, while the wing-venation is more like that of an early cockroach type. On these characters *Eugeron* has been referred to a separate extinct order, the Protohemiptera. In the Kansas rocks undoubted Homoptera occur, belonging to extinct families and the first Heteroptera appear in the Upper Trias of Ipswich (Australia), where they are represented by forms possibly ancestral

to shield bugs and water-boatmen. In Jurassic times both sub-orders are well represented and some of the dominant existing families differentiated. After the Jurassic period Hemiptera become more abundant as fossils, notably in the Miocene of Florissant and in Baltic amber.

Natural History.—By far the greater number of Hemiptera live and feed upon vegetation: a relatively small proportion suck

bibe it as it is actually being discharged. Some aphides are tended and sheltered by ants solely for the honey-dew they yield, while certain root-feeding Coccidae are tolerated in their nests for this same reason. Aquatic Hemiptera exhibit interesting adaptations for swimming and breathing in water. In the surface dwellers (Gymnocerata) these adaptations are less pronounced; the antennae are free and unconcealed, the legs not highly modified and these insects are clothed with a velvety pale below, which prevents wetting. The true aquatic forms (Cryptocerata) have the antennae concealed, the long antennae of surface forms obstructing the freedom of motion of submerged insects. The legs are highly modified as oars and various respiratory adaptations are present. They come to the surface to take in a supply of air at the caudal extremity, and this is retained in various ways for breathing while submerged. Many Hemiptera possess sound-producing organs and among shield-bugs wart-like tubercles on the hind legs are scraped across a set of fine ridges beneath the abdomen. In the Corixidae sound is produced by drawing a row of teeth on the fore tarsus across a series of pegs on the femur of the opposite leg. The loudest and most notorious stridulators are the cicadas whose notes have been variously compared to a railway whistle or a scissor-grinder; when numerous the noise

FROM DAVIDSON, "BULLETIN ON ENTOMOLOGICAL RESEARCH" BY COURTESY OF THE IMPERIAL BUREAU OF ENTOMOLOGY

FIG. 11.—BEAN APHID (*APHIS RUMICIS*), A MEMBER OF THE APHIDIDAE. During the spring and summer a number of generations of virgin females are produced, some winged, some wingless. These individuals bring forth living young, and in autumn the true males and females appear

the body-fluids of other insects or the blood of mammals and birds. The vegetable feeders may live on any part of a plant: aphides tend to congregate on the young sappy shoots, while a few live at the roots: scale-insects often heavily infest the bark, but there are many other kinds found on the leaves and fruit and some on the roots, while leafhoppers and frog-hoppers are abundant on almost all kinds of vegetation. A few species of aphides, scale-insects and Psyllidae form galls but the habit is rare within the order. The carnivorous members mostly prey upon other forms of insect life and this habit is characteristic of the family Reduviidae and of most of the water-bugs: some of the large species of the latter also attack tadpoles and small fish. Other of the carnivorous bugs subsist upon the blood of vertebrates. Members of the genus *Triatoma* (Reduviidae) are voracious blood-suckers in the Tropics and the species *T. megista* is the main carrier of the Trypanosome of a fatal human disease in South America. The bed-bugs (*Cimex*) infest man in most parts of the world where he is living under unhygienic conditions, while certain other members of the same family suck the blood of birds. Members of the curious tropical family *Polycnemidae* include about 20 species of wingless insects, which live deep down among the fur and suck the blood of bats: they are also remarkable in being viviparous, the young being brought forth relatively advanced in development.

Whatever their habits may be, all Hemiptera, upon emerging from the egg, live by piercing the plant or animal host, as the case may be, with their mouth-stylets. Their food always consists of fluids, either sap or blood and with the plant-feeders penetration of the tissues by the stylets is facilitated by the presence of enzymes in the insects' saliva. In some cases it appears that such enzymes are able to dissolve parts of the cell-walls and liquefy the surrounding tissues: and often the actual punctures are indicated by areas of discoloured necrotic cells. In some Hemiptera the saliva contains an enzyme which converts starch into sugar and, among many Homoptera, there appears to be an excess of sugars in their diet which is repeatedly voided in fluid drops from the anus in the form of honey-dew. Scale insects, aphides and Membracidae discharge large quantities of this material over the surrounding leaves which often become coated or discoloured by it. Honey-dew is very much sought after by ants which scour plants infested by these insects in order to im-

FROM "YEAR BOOK," AFTER HOWARD (U.S. DEPARTMENT OF AGRICULTURE)

FIGS. 12 AND 13.—THE APPLE SCALE INSECT (*LEPIDOSAPHES ULMI*). Above: female and eggs seen from beneath (left) and from above (right). Below: male apple scale. Magnified

emitted by these insects is both trying and monotonous to human ears. It is produced by a pair of drums or membranes within the metathorax, which are worked by special muscles and the cavities within which they lie are usually protected by a prominent plate on either side of the base of the abdomen. Cicadas (*q.v.*) are further remarkable for the length of their life-history in the case of certain species, the "periodical cicada" of North America requiring 13 to 17 years in order to complete its nymphal growth.

Economic Importance.—It has been observed that no other order of insects is so directly concerned with human welfare as

Hemiptera, on account of the vast amount of injury its members cause to vegetation by their sap-sucking propensity. Among the most notable of the noxious species are the cotton stainers (*Dysdercus*) whose punctures cause great injury to the bolls on account, more especially, of the bacterial and fungal infections which supervene. The chinch-bug (*Blissus leucopterus*) is stated to have caused probably over £70,000,000 damage in about 60 years to cereals in the United States. Among Capsidae tea blight (*Heliopeltis*) is very injurious in Assam, and other species attack fruit trees in Britain and other parts of Europe as well as North America. The green-house white-fly (*Asterochiton vaporariorum*) is a widely spread pest in hot-houses and other Aleurodidae infest citrus fruits. The Coccidae, however, are the most harmful of all Hemiptera and a mere list of the noxious forms would occupy at least a column: mention can only be made of the San José scale, the mussel or oyster shell scale and the cottony cushion scale, together with the various species of mealy-bugs (see SCALE INSECTS). The aphides (*q.v.*) compete closely with scale-insects in point of injurious behaviour. The woolly aphid of the apple, the bean aphid, the Phylloxera (*q.v.*) of the vine and Chermes with its allies are notable examples. Hemiptera also play an important rôle in the transmission of virus and other diseases among plants which is discussed in the article ENTOMOLOGY, ECONOMIC.

FROM RILEY AND HOWARD, "INSECT LIFE" (U.S. DEPARTMENT OF AGRICULTURE)
FIG. 14.—PASSIVE NYMPH, OR PUPA, OF MALE SCALE INSECT (COCYDIA)

From the point of view of utility to man a few members of the order may be classed as beneficial. The most important are the scale insects, notably the lac insect (*Tachardia lacca*) whose outer coverings yield the stick lac of commerce from which shellac is derived; the insect is native to India. The cochineal insect (*Dactylopius coccus*) belongs to the same family and the dyestuff, cochineal, is prepared from the dried females. Similarly the dye-stuff known as Kermes or "granum tinctorium" has been prepared from almost time immemorial from the dried females of another Coccid, viz., *Kermes ilicis*. Several other Coccidae yield wax in sufficient quantities to have been used commercially in the East, while the outer pearly coverings of *Margarodes* are the so-called ground-pearls which are strung into necklaces in South Africa and the Bahamas.

Mention needs to be made of the predatory Capsid *Cyrtorhinus mundulus* which has been utilised for purposes of controlling the sugar-cane leafhopper in the Hawaiian islands. The insect was introduced into that territory from Queensland and Fiji by F. Muir in 1920 and the experiment has since proved highly successful.

BIBLIOGRAPHY.—No general comprehensive work on Hemiptera exists, but text-books are available dealing with the British species, and the most important of these are the following: E. Saunders, *Hemiptera-Heteroptera of the British Isles* (1892); J. Edwards, *Hemiptera-Homoptera of the British Isles* (1896); E. A. Butler, *A Biology of the British Hemiptera-Heteroptera* (1923); R. Newstead, *British Coccidae* (1901-03) and F. V. Theobald, *British Aphides* (Ashford, Kent [1926-27] still in course of pub.).

For the North American Hemiptera a useful guide is W. E. Britton, *The Hemiptera or Sucking Insects of Connecticut* (Bull. 20 Conn. Geol. and Nat. Hist. Survey, 1923) and most of the species inhabiting that continent are listed by E. P. Van Duzee *Catalogue of the Hemiptera of America* (Univ. Calif. Tech. Bull., Agric. Exp. Station, 2, 1917). For the scale-insects consult A. D. MacGillivray, *The Coccidae* (Urbana, Ill., 1921) and for the aphides numerous bulletins by E. M. Patch, pub. by the Maine Agric. Experiment Station, are important. The same experiment station has also issued useful bull. (248 and 254: 1916) on froghoppers and leafhoppers by H. G. Osborn.

Among other works dealing with Hemiptera E. E. Green, *The Coccidae of Ceylon* (1896-1922) is comprehensive and beautifully illus. and the Lac insect is described by A. D. Imms and N. C. Chatterjee (*Indian Forest Memoirs*, 3, 1915). J. B. Buckton's *British Aphidae* (1875-1882) is now out of date, but useful for the coloured

illus.; see also J. Davidson, *Catalogue of British Aphididae* (1925: bibl.). For aquatic Hemiptera an account is given by L. C. Miall, *Natural History of Aquatic Insects* (1912) and by G. W. Kirkaldy, *Guide to the Study of British Waterbugs* (Entomologist, 1898-1906). For the Cicadas see W. L. Distant, *Oriental Cicadidae* (1889-92) and C. L. Marlatt, *The Periodical Cicada* (Bull. 71 U.S. Bureau of Entomol., 1907), while their sound-producing organs are described and figured by C. Carlet in *Annales des Sciences Naturelles* (ser. 6, vol. v. 1877). (A. D. I.)

HEMLOCK, the name commonly given in North America to trees of the genus *Tsuga*, of the pine family (Pinaceae), comprising nine species, five of which are native to eastern Asia and four to temperate North America. They are tall, pyramidal evergreen conifers, with cinnamon-red bark; slender, horizontal or somewhat drooping branches; flat, narrowly linear, short-stalked, two-ranked leaves and small, pendulous cones, with rounded, persistent, slightly woody scales.

The eastern hemlock (*T. canadensis*), called also Canada hemlock and hemlock-spruce, grows in upland forests from Nova Scotia to Minnesota and southward to Maryland, northern Indiana, south-western Wisconsin and in the mountains to Georgia and Alabama. It is a handsome tree, usually 60 to 80 ft. but sometimes 100 ft. high, with a trunk 2 to 4 ft. in diameter. The dark green leaves, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, are grooved above and marked with two whitish bands beneath. The bark is valuable for tanning and the soft, coarse-grained, splintery wood, though much inferior to pine or spruce, is extensively used for various building purposes. When young the eastern hemlock is one of the most ornamental of evergreens, and numerous varieties are in cultivation. It was introduced into Great Britain in 1736.

The much smaller Carolina hemlock (*T. caroliniana*), sometimes 70 ft. high, a beautiful but somewhat local tree of the southern Alleghenies from Virginia to Georgia, is extensively planted for ornament. The mountain hemlock (*T. Mertensiana*), also a small tree, 20 to 90 ft. high, with densely crowded leaves spreading around the branchlets, occurs on high mountains from south-eastern Alaska to Montana and California. Its soft light wood is of but little commercial value. The tree is sparingly grown as an ornamental.

The western hemlock (*T. heterophylla*), called also hemlock-fir and Prince Albert's fir, a valuable timber tree, often 200 ft. high, with a trunk 6 to 10 ft. in diameter, grows from south-eastern Alaska to northern Montana and central California, chiefly near the coast. In quality the wood of the western hemlock is greatly superior to that of all other hemlocks, comparing favourably with that of pine or spruce. In 1925 the total production of hemlock lumber in the United States was 2,139,631,000 bd. ft., of which 1,228,986,000 bd. ft. was western hemlock, cut in the States of Washington and Oregon, the remainder, except for small quantities of Carolina and mountain hemlock, being eastern hemlock. The cut of western hemlock in the State of Washington was 51% of all the hemlock lumber produced in the United States.

Two Japanese species are cultivated as ornamental trees, namely, Siebold's hemlock (*T. Sieboldii*), which sometimes grows 100 ft. high, with glossy branches and long-stalked cones, and the Japanese hemlock (*T. diversifolia*), sometimes attaining a height of 80 ft., with downy branchlets and short-stalked cones. (See GYMNOSPERMS.)

Various poisonous plants of the parsley family (*Umbelliferae*) are also called hemlock, as the poison hemlock and the water hemlock (*qq.v.*). The fool's-parsley (*Aethusa Cynapium*) is known as lesser or small hemlock. Because of the resemblance of its foliage to that of the eastern hemlock the American yew (*Taxus canadensis*) is frequently called ground hemlock. (See UMBELLIFERAE.)

HEMP, an annual herb (*Cannabis sativa*) having angular rough stems and deeply lobed leaves. The bast fibres of *Cannabis* are the hemp of commerce, but the products from many totally different plants are often included under the general name of hemp. In some cases the fibre is obtained from the stem, while in others it comes from the leaf. Sunn, Manila and Sisal hems and Phormium (New Zealand flax, which is neither flax nor hemp) are treated

separately. All these are often classed as hemp, and so are the following:—Ambari or Deccan hemp, *Hibiscus cannabinus*, an Indian and East Indian malvaceous plant, the fibre from which is often known as brown or Bombay hemp; Piteira or Mauritius hemp, which is obtained from Aloe creole, *Furcraea foetida willemetiana*, native in Brazil and cultivated in Mauritius; *Agave americana*; and Moorva or bowstring hemp, which is obtained from an aloe-like plant, *Sansevieria zeylanica*, and is a native of India and Ceylon.

Characteristics.—The hemp plant, like the hop, which is of the same family, Moraceae, is dioecious, i.e., the male and female flowers are borne on separate plants. The loose panicles of small yellow male flowers and the short spikes of green female flowers are borne in the axils of leaves at the top, or in clusters along the branches. The female flowers open only enough for the small feathery stigmas to protrude. Both male and female plants look alike until the time of flowering, after which the leaves on the male plants turn yellow and these plants die, while the female plants remain dark green about a month longer, or until the seeds ripen.

The plants have straight, erect, undivided stalks 3 to 18 feet high, generally about 5 to 8 feet when grown broadcast for fibre production. If not crowded or if planted in checks, as hemp is often cultivated for seed production, ascending leafy branches develop from nearly every node, but when sown broadcast for fibre production the crowded slender stalks are without branches or leaves except small tufts at the top.

Wild hemp still grows on the lower Ural, and the Volga, near the Caspian sea. It extends to Persia, the Altai range and northern and western China. "It is found in Kashmir and in the Himalaya, growing 10 to 12 ft. high, and thriving vigorously at an elevation of 6,000 to 10,000 ft." (*Pharmacographia*.) Wild hemp is little used for fibre but it produces a drug.

Origin and Distribution.—Hemp originated in some part of temperate Asia. The Emperor Shen Nung, in the twenty-eighth century B.C., taught the people of China to cultivate "ma," a plant, male and female, for fibre. According to Herodotus the Thracians and Scythians beyond the Caspian Sea used hemp; but it seems to have been unknown in western Europe until the beginning of the Christian era. Hemp was grown in France in the middle ages, primarily for the seeds which were used for food.

Hemp is now cultivated for fibre production in Russia, Italy, Jugoslavia, Rumania, Hungary, Poland, Spain, Belgium, France, Turkey, China, Japan, the United States and Chile. Other forms are cultivated for the narcotic drug cannabin, known in different forms and in different countries as hasheesh, bhang, gunga, charas, kif and marijuana, in India, Arabia, Africa and Mexico. In China, Manchuria and in some parts of Russia short stalked varieties of hemp are now cultivated for seed, which produces oil similar to linseed oil.

Although different forms have been described under different botanical names there are no essential differences in any of the specific characters and all cultivated and wild hemp is now recognized as belonging to one species, *Cannabis sativa* L.

Cultivation.—Hemp is an annual crop. The seed is sown as early in the spring as the land can be well prepared. The seed weighs 44 pounds per bushel and it is sown at the rate of 33 to 66 pounds per acre, the higher rate being sown on more fertile soils. The seed is sown broadcast by hand, or better with a drill, and the field is usually rolled after the seed is covered. In some places in Europe the fields are weeded by hand after the hemp is up, but if the land is well prepared and the seed sown early the dense growth of hemp will usually kill out all weeds that may start later. The crop is harvested when the staminate plants are in flower, about four months after seeding. In Europe and in China and Japan, it is usually cut by hand with a straight bladed sickle. In many fields the largest female plants are left to produce seed. After cutting, the stalks,—3 to 8 ft. long and about the thickness of a pencil,—are laid flat on the ground for 2 or 3 days, then set up in shocks for about a week. In the United States the crop is cut with self-rake reaping machines, or more often with large hemp harvesters which cut a swath $7\frac{1}{2}$ ft. wide and lay the stalks

smoothly and evenly on the ground where they remain until retted, requiring 3 to 6 weeks. The retted stalks are then picked up by another large machine which binds them in bundles. The bundles are set up in shocks to dry, after which they are hauled to the scutching mills and stored in sheds to await scutching. Hemp seed for sowing is there produced on plants grown in checks and cultivated like maize. This produces better seeds than are available from crowded plants grown broadcast for fibre production.

Preparation of Fibre.—In Italy and to some extent in other European countries, the hemp stalks, after curing in the shock, are tied in bundles and retted in water. They are left in the water from 10 to 20 days, or until the bark, including the fibre, separates easily from the woody, inner portion of the stalk. Some of the hemp in Italy, and much of it in other countries, is dew retted by spreading it on the ground where it is exposed to dew and rain. This method of retting requires 15 to 30 days, but it is the least expensive, for there is usually no cost except the work of spreading the stalks and picking them up. The hemp stalks, either dew-retted, or water-retted are set up in loose open shocks to dry. The fibre is separated from the dry stalks by means of hand brakes, or in northern Italy by power driven machines. In these machines handfuls of retted stalks pass endwise between rapidly revolving, fluted rollers, which break the woody portion into small pieces called hurds. The fibre is then held by hand so that the loosened hurds are beaten away by smooth projections on revolving cylinders. The Italian hemp is very carefully graded before being baled for shipment. In China and Japan some of the hemp fibre is prepared by steaming the stalks and stripping off the fibre by hand.

In the United States the work of scutching is done in winter, inside of buildings where it is independent of weather conditions. The retted stalks that have been stored in stacks or sheds, pass through long driers, then endwise through several pairs of fluted rollers, after which the fibre is turned sidewise and grasped near the centre by belts that take it past three pairs of scutching drums. The tow beaten out in scutching the long fibre and also that produced from short or tangled stalks, is cleaned by a tow machine. The hurds, used as fuel, furnish steam for the drier and for operating all of the machinery of the scutching mill.

Hemp Fibre.—Hemp is a soft fibre or bast fibre. It consists of very narrow flat strands from 3 to 10 ft. long. The ultimate cells composing these strands are $\frac{1}{4}$ to $1\frac{1}{2}$ in. long. Dew retted hemp is gray; Italian water-retted, light yellow or golden yellow; and Russian water-retted, usually greenish. Hemp is the strongest and most durable of any of the commercial soft fibres except flax. It is more nearly like flax than any other fibre, and the finest hemp is often used as a substitute for the coarser grades of flax. For more than 20 centuries hemp was the principal fibre used in ropes, but abacá (Manila hemp), stronger and lighter, has taken its place in marine cordage and in most other ropes, while jute, cheaper and more easily spun, but weaker and much less durable, has taken its place in sacking cloth, twines and for many purposes where hemp with its greater strength and durability would give better service.

Hemp is used in the manufacture of strong tying twines, sacking twine, book binders' twine, shoe and harness thread, net twine, carpet warp, marlines, canvas, sails, and in Europe it is used extensively in ropes of superior quality. Hemp tow is used in tarred oakum and in packing for pumps and engines.

Hemp as a Drug.—Hemp as a drug or intoxicant for smoking and chewing occurs in the three forms of bhang, ganja and charas. The medicinal and intoxicating properties of hemp have probably been known in oriental countries from a very early period. A Chinese herbal of about the 5th century B.C. and earlier, in part notices the seed and flower-bearing kinds of hemp. Other early writers refer to hemp as a remedy. The medicinal and dietetic use of hemp spread through India, Persia and Arabia in the early middle ages. Its modern medicinal use is chiefly due to trials by Dr. O'Shaughnessy in Calcutta (1838–1842). The plant is grown partly and often mainly for the sake of its resin in Persia, northern India and Arabia, in many parts of Africa and

Hemiptera, on account of the vast amount of injury its members cause to vegetation by their sap-sucking propensity. Among the most notable of the noxious species are the cotton stainers (*Dysdercus*) whose punctures cause great injury to the bolls on account, more especially, of the bacterial and fungal infections which supervene. The chinch-bug (*Blissus leucopterus*) is stated to have caused probably over £70,000,000 damage in about 60 years to cereals in the United States. Among Capsidae tea blight (*Heliopeltis*) is very injurious in Assam. and other species attack fruit trees in Britain and other parts of Europe as well as North America. The green-house white-fly (*Asterochiton vaporariorum*) is a widely spread pest in hot-houses and other Aleurodidae infest citrus fruits. The Coccidae, however, are the most harmful of all Hemiptera and a mere list of the noxious forms would occupy at least a column: mention can only be made of the San José scale, the mussel or oyster shell scale and the cottony cushion scale, together with the various species of mealy-bugs (see SCALE INSECTS). The aphides (*q.v.*) compete closely with scale-insects in point of injurious behaviour. The woolly aphis of the apple, the bean aphis, the Phylloxera (*q.v.*) of the vine and Chermes with its allies are notable examples. Hemiptera also play an important rôle in the transmission of virus and other diseases among plants which is discussed in the article ENTOMOLOGY, ECONOMIC.

From the point of view of utility to man a few members of the order may be classed as beneficial. The most important are the scale insects, notably the lac insect (*Tachardia lacca*) whose outer coverings yield the stick lac of commerce from which shellac is derived; the insect is native to India. The cochineal insect (*Dactylopius coccus*) belongs to the same family and the dyestuff, cochineal, is prepared from the dried females. Similarly the dye-stuff known as Kermes or "granum tinctorium" has been prepared from almost time immemorial from the dried females of another Coccid, viz., *Kermes ilicis*. Several other Coccidae yield wax in sufficient quantities to have been used commercially in the East, while the outer pearly coverings of *Margarodes* are the so-called ground-pearls which are strung into necklaces in South Africa and the Bahamas.

Mention needs to be made of the predatory Capsid *Cyrtorhinus mundulus* which has been utilised for purposes of controlling the sugar-cane leafhopper in the Hawaiian islands. The insect was introduced into that territory from Queensland and Fiji by F. Muir in 1920 and the experiment has since proved highly successful.

BIBLIOGRAPHY.—No general comprehensive work on Hemiptera exists, but text-books are available dealing with the British species, and the most important of these are the following: E. Saunders, *Hemiptera-Heteroptera of the British Isles* (1892); J. Edwards, *Hemiptera-Homoptera of the British Isles* (1896); E. A. Butler, *A Biology of the British Hemiptera-Heteroptera* (1923); R. Newstead, *British Coccidae* (1901-03) and F. V. Theobald, *British Aphides* (Ashford, Kent [1926-27] still in course of pub.).

For the North American Hemiptera a useful guide is W. E. Britton, *The Hemiptera or Sucking Insects of Connecticut* (Bull. 20 Conn. Geol. and Nat. Hist. Survey, 1923) and most of the species inhabiting that continent are listed by E. P. Van Duzee *Catalogue of the Hemiptera of America* (Univ. Calif. Tech. Bull., Agric. Exp. Station, 2, 1917). For the scale-insects consult A. D. MacGillivray, *The Coccidae* (Urbana, Ill., 1921) and for the aphides numerous bulletins by E. M. Patch, pub. by the Maine Agric. Experiment Station, are important. The same experiment station has also issued useful bull. (248 and 254: 1916) on froghoppers and leafhoppers by H. G. Osborn.

Among other works dealing with Hemiptera E. E. Green, *The Coccidae of Ceylon* (1896-1922) is comprehensive and beautifully illus. and the Lac insect is described by A. D. Imms and N. C. Chatterjee (*Indian Forest Memoirs*, 3, 1915). J. B. Buckton's *British Aphidae* (1875-1882) is now out of date, but useful for the coloured

illus.; see also J. Davidson, *Catalogue of British Aphididae* (1925: bibl.). For aquatic Hemiptera an account is given by L. C. Miall, *Natural History of Aquatic Insects* (1912) and by G. W. Kirkaldy, *Guide to the Study of British Waterbugs* (Entomologist, 1898-1906). For the Cicadas see W. L. Distant, *Oriental Cicadidae* (1889-92) and C. L. Marlatt, *The Periodical Cicada* (Bull. 71 U.S. Bureau of Entomol., 1907), while their sound-producing organs are described and figured by C. Carlet in *Annales des Sciences Naturelles* (ser. 6, vol. v. 1877).

(A. D. I.)

FROM RILEY AND HOWARD, "INSECT LIFE" (U.S. DEPARTMENT OF AGRICULTURE)

FIG. 14.—PASSIVE NYMPH, OR PUPA, OF MALE SCALE INSECT (ICERYA)

HEMLOCK, the name commonly given in North America to trees of the genus *Tsuga*, of the pine family (Pinaceae), comprising nine species, five of which are native to eastern Asia and four to temperate North America. They are tall, pyramidal evergreen conifers, with cinnamon-red bark; slender, horizontal or somewhat drooping branches; flat, narrowly linear, short-stalked, two-ranked leaves and small, pendulous cones, with rounded, persistent, slightly woody scales.

The eastern hemlock (*T. canadensis*), called also Canada hemlock and hemlock-spruce, grows in upland forests from Nova Scotia to Minnesota and southward to Maryland, northern Indiana, south-western Wisconsin and in the mountains to Georgia and Alabama. It is a handsome tree, usually 60 to 80 ft. but sometimes 100 ft. high, with a trunk 2 to 4 ft. in diameter. The dark green leaves, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, are grooved above and marked with two whitish bands beneath. The bark is valuable for tanning and the soft, coarse-grained, splintery wood, though much inferior to pine or spruce, is extensively used for various building purposes. When young the eastern hemlock is one of the most ornamental of evergreens, and numerous varieties are in cultivation. It was introduced into Great Britain in 1736.

The much smaller Carolina hemlock (*T. caroliniana*), sometimes 70 ft. high, a beautiful but somewhat local tree of the southern Alleghenies from Virginia to Georgia, is extensively planted for ornament. The mountain hemlock (*T. Mertensiana*), also a small tree, 20 to 90 ft. high, with densely crowded leaves spreading around the branchlets, occurs on high mountains from south-eastern Alaska to Montana and California. Its soft light wood is of but little commercial value. The tree is sparingly grown as an ornamental.

The western hemlock (*T. heterophylla*), called also hemlock-fir and Prince Albert's fir, a valuable timber tree, often 200 ft. high, with a trunk 6 to 10 ft. in diameter, grows from south-eastern Alaska to northern Montana and central California, chiefly near the coast. In quality the wood of the western hemlock is greatly superior to that of all other hemlocks, comparing favourably with that of pine or spruce. In 1925 the total production of hemlock lumber in the United States was 2,139,631,000 bd. ft., of which 1,228,986,000 bd. ft. was western hemlock, cut in the States of Washington and Oregon, the remainder, except for small quantities of Carolina and mountain hemlock, being eastern hemlock. The cut of western hemlock in the State of Washington was 51% of all the hemlock lumber produced in the United States.

Two Japanese species are cultivated as ornamental trees, namely, Siebold's hemlock (*T. Sieboldii*), which sometimes grows 100 ft. high, with glossy branches and long-stalked cones, and the Japanese hemlock (*T. diversifolia*), sometimes attaining a height of 80 ft., with downy branchlets and short-stalked cones. (See GYMNOSPERMS.)

Various poisonous plants of the parsley family (*Umbelliferae*) are also called hemlock, as the poison hemlock and the water hemlock (*qq.v.*). The fool's-parsley (*Aethusa Cynapium*) is known as lesser or small hemlock. Because of the resemblance of its foliage to that of the eastern hemlock the American yew (*Taxus canadensis*) is frequently called ground hemlock. (See UMBELLIFERAE.)

HEMP, an annual herb (*Cannabis sativa*) having angular rough stems and deeply lobed leaves. The bast fibres of *Cannabis* are the hemp of commerce, but the products from many totally different plants are often included under the general name of hemp. In some cases the fibre is obtained from the stem, while in others it comes from the leaf. Sunn, Manila and Sisal hems and Phormium (New Zealand flax, which is neither flax nor hemp) are treated

separately. All these are often classed as hemp, and so are the following:—Ambari or Deccan hemp, *Hibiscus cannabinus*, an Indian and East Indian malvaceous plant, the fibre from which is often known as brown or Bombay hemp; Piteira or Mauritius hemp, which is obtained from Aloe creole, *Furcraea foetida willemetiana*, native in Brazil and cultivated in Mauritius; *Agave americana*; and Moorva or bowstring hemp, which is obtained from an aloe-like plant, *Sansevieria zeylanica*, and is a native of India and Ceylon.

Characteristics.—The hemp plant, like the hop, which is of the same family, Moraceae, is dioecious, i.e., the male and female flowers are borne on separate plants. The loose panicles of small yellow male flowers and the short spikes of green female flowers are borne in the axils of leaves at the top, or in clusters along the branches. The female flowers open only enough for the small feathery stigmas to protrude. Both male and female plants look alike until the time of flowering, after which the leaves on the male plants turn yellow and these plants die, while the female plants remain dark green about a month longer, or until the seeds ripen.

The plants have straight, erect, undivided stalks 3 to 18 feet high, generally about 5 to 8 feet when grown broadcast for fibre production. If not crowded or if planted in checks, as hemp is often cultivated for seed production, ascending leafy branches develop from nearly every node, but when sown broadcast for fibre production the crowded slender stalks are without branches or leaves except small tufts at the top.

Wild hemp still grows on the lower Ural, and the Volga, near the Caspian sea. It extends to Persia, the Altai range and northern and western China. "It is found in Kashmir and in the Himalaya, growing 10 to 12 ft. high, and thriving vigorously at an elevation of 6,000 to 10,000 ft." (*Pharmacographia*.) Wild hemp is little used for fibre but it produces a drug.

Origin and Distribution.—Hemp originated in some part of temperate Asia. The Emperor Shen Nung, in the twenty-eighth century B.C., taught the people of China to cultivate "ma," a plant, male and female, for fibre. According to Herodotus the Thracians and Scythians beyond the Caspian Sea used hemp; but it seems to have been unknown in western Europe until the beginning of the Christian era. Hemp was grown in France in the middle ages, primarily for the seeds which were used for food.

Hemp is now cultivated for fibre production in Russia, Italy, Jugoslavia, Rumania, Hungary, Poland, Spain, Belgium, France, Turkey, China, Japan, the United States and Chile. Other forms are cultivated for the narcotic drug cannabin, known in different forms and in different countries as hasheesh, bhang, gunga, charas, kif and marijuana, in India, Arabia, Africa and Mexico. In China, Manchuria and in some parts of Russia short stalked varieties of hemp are now cultivated for seed, which produces oil similar to linseed oil.

Although different forms have been described under different botanical names there are no essential differences in any of the specific characters and all cultivated and wild hemp is now recognized as belonging to one species, *Cannabis sativa* L.

Cultivation.—Hemp is an annual crop. The seed is sown as early in the spring as the land can be well prepared. The seed weighs 44 pounds per bushel and it is sown at the rate of 33 to 66 pounds per acre, the higher rate being sown on more fertile soils. The seed is sown broadcast by hand, or better with a drill, and the field is usually rolled after the seed is covered. In some places in Europe the fields are weeded by hand after the hemp is up, but if the land is well prepared and the seed sown early the dense growth of hemp will usually kill out all weeds that may start later. The crop is harvested when the staminate plants are in flower, about four months after seeding. In Europe and in China and Japan, it is usually cut by hand with a straight bladed sickle. In many fields the largest female plants are left to produce seed. After cutting, the stalks,—3 to 8 ft. long and about the thickness of a pencil,—are laid flat on the ground for 2 or 3 days, then set up in shocks for about a week. In the United States the crop is cut with self-rake reaping machines, or more often with large hemp harvesters which cut a swath $7\frac{1}{2}$ ft. wide and lay the stalks

smoothly and evenly on the ground where they remain until retted, requiring 3 to 6 weeks. The retted stalks are then picked up by another large machine which binds them in bundles. The bundles are set up in shocks to dry, after which they are hauled to the scutching mills and stored in sheds to await scutching. Hemp seed for sowing is there produced on plants grown in checks and cultivated like maize. This produces better seeds than are available from crowded plants grown broadcast for fibre production.

Preparation of Fibre.—In Italy and to some extent in other European countries, the hemp stalks, after curing in the shock, are tied in bundles and retted in water. They are left in the water from 10 to 20 days, or until the bark, including the fibre, separates easily from the woody, inner portion of the stalk. Some of the hemp in Italy, and much of it in other countries, is dew retted by spreading it on the ground where it is exposed to dew and rain. This method of retting requires 15 to 30 days, but it is the least expensive, for there is usually no cost except the work of spreading the stalks and picking them up. The hemp stalks, either dew-retted, or water-retted are set up in loose open shocks to dry. The fibre is separated from the dry stalks by means of hand brakes, or in northern Italy by power driven machines. In these machines handfuls of retted stalks pass endwise between rapidly revolving, fluted rollers, which break the woody portion into small pieces called hurds. The fibre is then held by hand so that the loosened hurds are beaten away by smooth projections on revolving cylinders. The Italian hemp is very carefully graded before being baled for shipment. In China and Japan some of the hemp fibre is prepared by steaming the stalks and stripping off the fibre by hand.

In the United States the work of scutching is done in winter, inside of buildings where it is independent of weather conditions. The retted stalks that have been stored in stacks or sheds, pass through long driers, then endwise through several pairs of fluted rollers, after which the fibre is turned sidewise and grasped near the centre by belts that take it past three pairs of scutching drums. The tow beaten out in scutching the long fibre and also that produced from short or tangled stalks, is cleaned by a tow machine. The hurds, used as fuel, furnish steam for the drier and for operating all of the machinery of the scutching mill.

Hemp Fibre.—Hemp is a soft, fibre or bast fibre. It consists of very narrow flat strands from 3 to 10 ft. long. The ultimate cells composing these strands are $\frac{1}{4}$ to $1\frac{1}{2}$ in. long. Dew retted hemp is gray; Italian water-retted, light yellow or golden yellow; and Russian water-retted, usually greenish. Hemp is the strongest and most durable of any of the commercial soft fibres except flax. It is more nearly like flax than any other fibre, and the finest hemp is often used as a substitute for the coarser grades of flax. For more than 20 centuries hemp was the principal fibre used in ropes, but abacá (Manila hemp), stronger and lighter, has taken its place in marine cordage and in most other ropes, while jute, cheaper and more easily spun, but weaker and much less durable, has taken its place in sacking cloth, twines and for many purposes where hemp with its greater strength and durability would give better service.

Hemp is used in the manufacture of strong tying twines, sacking twine, book binders' twine, shoe and harness thread, net twine, carpet warp, marlines, canvas, sails, and in Europe it is used extensively in ropes of superior quality. Hemp tow is used in tarred oakum and in packing for pumps and engines.

Hemp as a Drug.—Hemp as a drug or intoxicant for smoking and chewing occurs in the three forms of bhang, ganja and charas. The medicinal and intoxicating properties of hemp have probably been known in oriental countries from a very early period. A Chinese herbal of about the 5th century B.C. and earlier, in part notices the seed and flower-bearing kinds of hemp. Other early writers refer to hemp as a remedy. The medicinal and dietetic use of hemp spread through India, Persia and Arabia in the early middle ages. Its modern medicinal use is chiefly due to trials by Dr. O'Shaughnessy in Calcutta (1838-1842). The plant is grown partly and often mainly for the sake of its resin in Persia, northern India and Arabia, in many parts of Africa and

in Brazil.

Pharmacology and Therapeutics.—The composition of this drug is still extremely obscure; partly, perhaps, because it varies so much in individual specimens. It appears to contain at least two alkaloids—cannabinine and tetano-cannabinine—of which the former is volatile. The chief active principle may possibly be neither of these, but the substance cannabinon. There are also resins, a volatile oil and several other constituents. *Cannabis indica*—as the drug is termed in the pharmacopoeias—may be given as an extract (dose $\frac{1}{4}$ –1 gr.) or tincture (dose 5–15 minims).

The drug has no external action. The apparent impossibility of obtaining it in pure and trustworthy form has led to its entire abandonment in therapeutics. When a good sample is obtained it is a safe and efficient hypnotic, at any rate in the case of a European. The tincture should not be prescribed unless precautions are taken to avoid the precipitation of the resin which follows its dilution with water.

See Watt, *Dictionary of the Economic Products of India*.

HEMPSTEAD, a village of Nassau county, New York, U.S.A., 5 m. E. of the Brooklyn city limits; served by the Long Island railroad. The population in 1925 was 9,952. It is a residential suburb and a summer resort, a trade centre, and has aeroplane and other factories. Mitchel Field, an Air Corps training camp, is near by. The village was incorporated in 1853.

HEMSTERHUIS, FRANÇOIS (1721–1790), Dutch writer on aesthetics and moral philosophy, was born at Franeker, on Dec. 27, 1721. Educated at the university of Leyden, he was for many years secretary to the state council of the United Provinces. He died at The Hague on July 7, 1790. Through his philosophical writings he met many distinguished persons—Goethe, Herder, Princess Amalia of Gallitzin, and especially Jacobi, who, like himself, was an idealist. His philosophy, strongly platonic, was founded on the desire for self-knowledge and truth.

His chief works are: *Lettre sur la sculpture* (1769), in which occurs the well-known definition of the Beautiful as “that which gives us the greatest number of ideas in the shortest space of time”; its continuation, *Lettre sur les désirs* (1770); *Lettre sur l'homme et ses rapports* (1772); *Sopyle* (1778), an attack on materialism; *Aristée* (1779), the “theodicy” of Hemsterhuis; *Simon* (1787), discussing the will, the imagination, the moral principle (both passive and active); *Alexis* (1787); *Lettre sur l'athéisme* (1787). The last collected edition of his works appeared at Leipzig 1912, 2 vols.

See C. Boulan, *F. Hemsterhuis le Socrate Hollandais* (1924); J. E. Poritzky, *Franz Hemsterhuis* (1926).

HEMSTERHUIS, TIBERIUS (1685–1766), Dutch philologist and critic, was born on Jan. 9, 1685, at Groningen in Holland, and died at Leyden on April 7, 1766. He was professor of Greek at Franeker from 1717 to 1740, and then at Leyden, and was also a mathematician and philosopher. In 1706 he completed Lederlin's edition of Pollux's *Onomasticon*. This was widely admired, but he was much mortified by the criticism of Bentley. Hemsterhuis was the founder of a laborious and useful Dutch school of criticism, which had famous disciples in Valckenaer, Lennep and Ruhnken.

See *Elogium T. Hemsterhusii* (with Bentley's letters) by Ruhnken (1789), and *Supplementa annotationis ad elogium T. Hemsterhusii*, etc. (Leyden, 1874); also J. E. Sandys' *Hist. Class. Scholarship*, ii. (1908).

HEMY, CHARLES NAPIER (1841–1917), British painter, born at Newcastle-on-Tyne, was trained in the Newcastle school of art, in the Antwerp academy and in the studio of Baron Leys. He is best known by his admirable marine paintings. He was elected an A.R.A. in 1898, associate of the Royal Society of Painters in Water Colours in 1890 and member in 1897. Two of his paintings, “Pilchards” (1897) and “London River” (1904), are in the National Gallery of British Art. He died at Falmouth on Sept. 30, 1917.

HEN, the female of any bird, especially of the common fowl. (See POULTRY AND POULTRY FARMING, FOWL.)

HÉNAULT, CHARLES JEAN FRANÇOIS (1685–1770), French historian, was born in Paris. He became coun-

cillor of the *parlement* of Paris (1705), president of the court of *enquêtes* (1710) and superintendent of the household of Queen Marie Leszczyńska (1753). On his recovery in his 80th year from a dangerous malady (1765) he professed to have undergone religious conversion and retired into private life, but his religion did not prevent him from continuing his friendship with Voltaire. Hénault wrote the *Abrégé chronologique de l'histoire de France*, first published anonymously in 1744, which had a prodigious success, and was translated into several languages, even into Chinese. He died at Paris on Nov. 24, 1770.

See Sainte-Beuve, *Causeries du lundi*, vol. xi.; and H. Lion, *Le Président Hénault* (1903).

HENBANE, the common name of the plant *Hyoscyamus niger*, a member of the family Solanaceae, indigenous to Britain, found wild in waste places, on rubbish about villages and old castles, and cultivated for medicinal use in various counties in the south and east of England. It occurs also in central and southern Europe and in Western Asia extending to India and Siberia, and has long been naturalized in the United States. There are two forms of the plant, an annual and a biennial, which spring indifferently from the same crop of seed—the one growing on during the summer to a height of from 1 to 2 ft., and flowering and perfecting seed; the other producing the first season only a tuft of radical leaves, which disappear in winter, leaving underground a thick fleshy root, from the crown of which arises in spring a branched flowering stem, usually much taller and more vigorous than the flowering stems of the annual plants.

The biennial form is that which is considered officinal. The radical leaves of this biennial plant spread out flat on all sides from the crown of the root; they are ovate-oblong, acute, stalked, and more or less incisely-toothed, of a greyish-green colour, and covered with viscid hairs; these leaves perish at the approach of winter. The flowering stem pushes up from the root-crown in spring, ultimately reaching from 3 to 4 ft. in height, and as it grows becoming branched, and furnished with alternate sessile leaves, which are stem-clasping, oblong, unequally-lobed, clothed with glandular clammy hairs, and of a dull grey-green, the whole plant having a powerful nauseous odour. The flowers are short-stalked, the lower ones growing in the fork of the branches, the upper ones sessile in one-sided leafy spikes which are rolled back at the top before flowering, the leaves becoming smaller upwards and taking the place of bracts. The flowers have an urn-shaped calyx which persists around the fruit and is strongly veined, with five stiff, broad, almost prickly lobes; these, when the soft matter is removed by maceration, form very elegant specimens when associated with leaves prepared in a similar way. The corollas are obliquely funnel-shaped, of a dirty yellow or buff, marked with a close reticulation of purple veins. The capsule opens transversely by a convex lid and contains numerous seeds.

Both the leaves and the seeds are employed in pharmacy. The Mohammedan doctors of India are accustomed to prescribe the seeds. Henbane yields a poisonous alkaloid, *hyoscyamine*, which is stated to have properties almost identical with those of atropine, from which it differs in being more soluble in water. It is usually obtained in an amorphous, scarcely ever in a crystalline, state. In small and repeated doses henbane has been found to have a tranquillizing effect upon persons affected by severe nervous irritability. In poisonous doses it causes loss of speech and paralysis. In the form of extract or tincture it is a valuable remedy in the hands of a medical man, either as an anodyne, a hypnotic or a sedative. The smoking of the seeds and capsules of henbane is noted in books as a somewhat dangerous remedy adopted by country people for toothache. Accidental poisoning from henbane occasionally occurs, owing sometimes to the apparent edibility and wholesomeness of the root.

HENCHMAN, one who attended on a horse, a groom, and hence, like groom (*q.v.*), a title of a subordinate official in royal or noble households. The first part of the word is the O.E. *hengest*, a horse. The word appears in the name, Hengest, of the Saxon chieftain (see HENGEST AND HORSAS). HENCHMEN, pages of honour or squires, rode or walked at the side of their master in processions, and appear in the English royal household from

the 14th century till Elizabeth abolished the royal henchmen, known also as the "children of honour."

HENDERSON, ALEXANDER (1583-1646), Scottish ecclesiastic, born at Criech, Fifeshire, graduated at the University of St. Andrews in 1603, and in 1610 was appointed professor of rhetoric and philosophy and questor of the faculty of arts. Shortly after this he was presented to the living of Leuchars. As Henderson was forced upon his parish by Archbishop George Gladstones, and was known to sympathize with episcopacy, his settlement was at first extremely unpopular; but he subsequently became a Presbyterian in doctrine and church government, and one of the most esteemed ministers in Scotland. He was one of the petitioners against the "five Acts" and later against the introduction of a service-book and canons drawn up on the model of the English prayer-book. On March 1, 1638, the public signing of the "National Covenant" began in Greyfriars church, Edinburgh. Henderson was mainly responsible for the final form of this document. In July of the same year he proceeded to the north to debate on the "Covenant" with the Aberdeen doctors. He was moderator of the famous Assembly which met in Glasgow on Nov. 21, 1638. Henderson was then transferred to Edinburgh; he had been at Leuchars for about 23 years, and was extremely reluctant to leave it.

While Scotland and England were preparing for the "First Bishops' War," Henderson drew up two papers, entitled respectively *The Remonstrance of the Nobility and Instructions for Defensive Arms*. The first of these documents he published himself; the second was published against his wish by John Corbet (1603-41), a deposed minister. In the negotiations for peace at Birks after the war Henderson was one of the Scottish commissioners, and made a very favourable impression on the king. In 1640 Henderson was elected by the town council rector of Edinburgh university—an office to which he was annually re-elected till his death. The Pacification of Birks had been wrung from the king; and the Scots, seeing that he was preparing for the "Second Bishops' War," took the initiative, and pressed into England so vigorously that Charles had again to yield everything. The maturing of the treaty of peace took time, and Henderson again took part in the negotiations, first at Ripon (Oct. 1) and afterwards in London. In London he had a personal interview with the king, with the view of obtaining assistance for the Scottish universities from the money formerly applied to the support of the bishops. On Henderson's return to Edinburgh in July 1641 the Assembly was sitting at St. Andrews. To suit the convenience of the parliament, however, it removed to Edinburgh; Henderson was elected moderator of the Edinburgh meeting. In this Assembly he proposed that "a confession of faith, a catechism, a directory for all the parts of the public worship, and a platform of government, wherein possibly England and we might agree," should be drawn up. This was unanimously approved of, and the laborious undertaking was left in Henderson's hands; but the "notable motion" did not lead to any immediate results. During Charles's second State-visit to Scotland, in the autumn of 1641, Henderson acted as his chaplain, and managed to get the funds, formerly belonging to the bishopric of Edinburgh, applied to the metropolitan university. In 1642 Henderson, whose policy was to keep Scotland neutral in the war which had now broken out between the king and the parliament, corresponded with England on ecclesiastical topics; and, shortly afterwards, he was sent to Oxford to mediate between the king and his parliament; but his mission proved a failure.

At the meeting of the General Assembly held in Aug. 1643, Henderson was elected moderator for the third time. He presented a draft of the famous "Solemn League and Covenant," which was received with enthusiasm. Unlike the "National Covenant" of 1638, which applied to Scotland only, this document was common to the two kingdoms. Henderson, Baillie, Rutherford and others were sent up to London to represent Scotland in the Assembly at Westminster. The "Solemn League and Covenant" passed the two Houses of parliament and the Westminster Assembly, and thus became law for the two kingdoms. As Scottish commissioner to the Westminster Assembly, Hender-

son was in England from Aug. 1643 till Aug. 1646; his principal work was the drafting of the directory for public worship. Early in 1645 he was sent to Uxbridge to aid the commissioners of the two parliaments in negotiating with the king; but nothing came of the conference. In 1646 the king joined the Scottish army; and, after retiring with them to Newcastle, he sent for Henderson, and discussed with him the two systems of church government in a number of papers. Meanwhile Henderson was failing in health. He sailed to Scotland, and eight days after his arrival died, on Aug. 19, 1646. He was buried in Greyfriars churchyard, Edinburgh; and his death was the occasion of national mourning in Scotland. A document was published in London purporting to be a "Declaration of Mr. Alexander Henderson made upon his death-bed"; and, although this paper was disowned, denounced and shown to be false in the General Assembly of Aug. 1648, the document was used by Clarendon as giving the impression that Henderson had recanted. Its foundation was probably certain expressions lamenting Scottish interference in English affairs.

Henderson is one of the greatest men in the history of Scotland and, next to Knox, is certainly the most famous of Scottish ecclesiastics. He had great political genius; and his statesmanship was so influential that "he was," as Masson well observes, "a cabinet minister without office." He has made a deep mark on the history, not only of Scotland, but of England; and the existing Presbyterian churches in Scotland are largely indebted to him for the forms of their dogmas and their ecclesiastical organization. He is thus justly considered the second founder of the Reformed Church in Scotland.

See J. Aiton, *Life and Times of Alexander Henderson* (1836); T. McCrie, *Life of Alexander Henderson* (1836); J. P. Thomson, *Alexander Henderson, the Covenanter* (1912); R. L. Orr, *Alexander Henderson, Churchman and Statesman* (1919); also *The Letters and Journals of Robert Baillie* (1841-42), an exceedingly valuable work from an historical point of view; J. H. Burton, *History of Scotland* (2nd ed., 8 vols., 1873); D. Masson, *Drummond of Hawthornden* (1873) and *Life of Milton* (7 vols., 1859-94); Andrew Lang, *History of Scotland*, (vol. iii., 1907). Henderson's own works are chiefly contributions to current controversies, speeches and sermons.

HENDERSON, ARTHUR (1863-), British politician, was born in Glasgow of working-class parents on Sept. 15, 1863; but his work and interests subsequently lay at Newcastle (where he served an apprenticeship as moulder at Robert Stephenson & Co.'s works), and in the county of Durham. He became prominent in the trade union movement. He was for some years a member of the Newcastle city council and the Darlington borough council. He was mayor in 1903; and was made a magistrate for the county of Durham. He entered parliament for Barnard Castle, as a Labour member, at a by-election in 1903, and soon made his mark. In 1908 he was elected chairman of the party, a post which he held for two years and to which he was re-elected after the outbreak of war in 1914, when the then chairman, Ramsay MacDonald, had to resign owing to his pacifist views. As chairman, at the opening of the new session in that autumn, Henderson promised the full support of organized Labour in maintaining the "splendid unity" of the nation.

When the first Coalition Ministry was formed by H. H. Asquith in 1915, Henderson was included in the cabinet mainly as adviser of the Government on labour questions arising out of the World War, with the office, first of president of the board of education, and afterwards of paymaster general. He showed himself resolved on a strenuous prosecution of the war, strongly advocating both the Munitions Bill and the Registration Bill, and having no hesitation in taking the further step of compulsory service. He followed up this action by urging the Labour Party to rally in Dec. 1916 to Lloyd George, and by accepting himself the position of an original member of the war cabinet of four without portfolio. In the spring of 1917 he visited Russia, just after the Revolution, on behalf of the British Government, and found the then provisional Government at St. Petersburg (Leningrad) strongly in favour of an international labour and socialist conference, which was to meet at Stockholm under the auspices of the International Socialist Bureau. He came to the conclusion that, provided the conference were merely consultative, it would be better that British representatives should go, rather than permit Russian rep-

representatives to meet German representatives there alone; and accordingly, on his return to England, being still secretary of the Labour Party as well as a member of the war cabinet, he promoted the participation of British Labour therein. Two Labour Party conferences endorsed his attitude, but the Sailors and Firemen's Union refused to carry the delegates; and most other Labour Parties in allied countries did not follow his lead. Mr. Lloyd George and his fellow cabinet ministers indicated publicly their dissent from his policy, in terms which immediately led to his resignation.

Henderson espoused the Labour decision of the latter part of 1918 to take the Labour men out of the government and to appeal for support on a purely Labour platform. This cost him his seat in Parliament at the general election of Dec. 1918. Indeed, ill-luck pursued him also at the next two general elections, in 1922 and 1923; but in all three cases he returned to the House of Commons a few months later at a by-election. In the parliament of 1923-4 he had the satisfaction of having two sons as fellow members, though they were both defeated in the autumn of 1924. In MacDonald's ministry he was secretary of state for home affairs. He actively endorsed the policy of his party in 1925-6 in severing themselves definitely from the Communists.

HENDERSON, EBENEZER (1784-1858), a Scottish divine, was born at the Linn near Dunfermline on Nov. 17, 1784, and died at Mortlake on May 17, 1858. He spent his life in missionary work in northern and eastern Europe, becoming in 1806 pastor at Elsinore. From this time till about 1817 he was engaged in encouraging the distribution of Bibles in northern Europe, as an agent of the British and Foreign Bible society.

On Oct. 6, 1811 he formed the first Congregational church in Sweden. In 1818, after a visit to England, Henderson travelled in company with Paterson through Russia as far south as Tiflis. In 1822 he was invited by Prince Alexander (Galitzin) to assist the Russian Bible society in translating the Scriptures into various languages spoken in the Russian empire. In 1825 Henderson was appointed tutor of the Mission college, Gosport, and thereafter worked in his own country.

See T. S. Henderson, *Memoirs of Ebenezer Henderson* (1859); *Congregational Year Book* (1859).

HENDERSON, GEORGE FRANCIS ROBERT (1854-1903), British soldier and military writer, was born in Jersey in 1854. He entered the army in 1878, and served in the Egyptian campaign of 1882. In garrison at Gibraltar, in Bermuda and in Nova Scotia, he studied military art and history in spite of the difficulties of research, and in 1889 appeared (anonymously) his first work, *The Campaign of Fredericksburg*. In the same year he became instructor in tactics, military law and administration at Sandhurst. From this post he proceeded as professor of military art and history to the staff college (1892-99), and there exercised a profound influence on the younger generation of officers. His study on *Spiceren* had been begun some years before, and in 1898 appeared, as the result of eight years' work, his masterpiece, *Stonewall Jackson and the American Civil War*. In the South African War Lieutenant-Colonel Henderson served on the staff of Lord Roberts as director of intelligence. He was to have written the official history of the war, but failing health obliged him to go to Egypt, where he died at Aswan on March 5, 1903.

Various lectures and papers by Henderson were collected and published in 1905 by Captain Malcolm, D.S.O., under the title *The Science of War*; to this collection a memoir was contributed by Lord Roberts. See also *Journal of the Royal United Service Institution*, vol. xlvii, No. 302.

HENDERSON, JOHN (1747-1785), English actor, of Scottish descent, was born in London. He made his first appearance on the stage at Bath on Oct. 6, 1772 as Hamlet. His success in this and other Shakespearian parts led to his being called the "Bath Roscius." He appeared at the Haymarket, London, in 1777 as Shylock. Sheridan then engaged him to play at Drury Lane, where he remained for two years. When the companies joined forces he went to Covent Garden, appearing as Richard III. in 1778, and creating original parts in many of the plays of Cumberland, Shirley, Jephson and others. His last appearance was in 1785 as Horatius in *The Roman Father*, and he died on Nov. 25

of that year and was buried in Westminster abbey. Henderson was a close friend of Gainsborough, who painted his portrait, as did also Stewart and Romney.

HENDERSON, WILLIAM JAMES (1855-), American music critic and author, was born at Newark (N.J.), on Dec. 4, 1855. Graduating at Princeton (1876), he was on the *New York Times* (1883-1902) and the *New York Sun* (from 1902 onward) as music critic, and was associate editor of the *Standard Dictionary*, 1892-93. With Richard Aldrich, James Huneker and Henry E. Krehbiel, he established himself as one of the foremost American critics of his day and on his 70th birthday he was hailed as the *doyen* of New York music writers. He adapted a number of operetta librettos, including *Le Petit Duc*, produced at the Casino theatre, and the libretto for Walter Damrosch's *Cyrano de Bergerac*; he wrote *The Little Duke* in collaboration with H. C. Bunner; also a number of books on music and the sea.

HENDERSON, a city of north-western Kentucky, U.S.A., on the Ohio river, 12m. below Evansville, Ind.; the county seat of Henderson county. It is on Federal highways 41 and 60, and is served by the Illinois Central, the Louisville and Nashville, and the Louisville, Henderson and St. Louis railways. The population was 12,169 in 1920 (24% negroes) and was estimated locally at 14,500 in 1928. The city is built on the high bank of the river, well above flood level. Coal is mined in the region and there are three mines within the city limits. The county produces especially hogs, corn and fruit. The city has many tobacco-stemming plants, a large cotton mill, and various other manufacturing industries. The factory output in 1925 was valued at \$4,811,182. Henderson (originally called Red Banks) was settled in 1784, named after Richard Henderson (1734-85), laid out by his company in 1797, incorporated as a town in 1810, and chartered as a city in 1854.

HENDERSON, a city of North Carolina, U.S.A., 44m. N. by E. of Raleigh; the county seat of Vance county. It is on Federal highway 1, and is served by the Seaboard Air Line and the Southern railways. The population was 5,222 in 1920 (39% negroes). It has large cotton mills (100,000 spindles in 1928), and is an important market for cotton and leaf tobacco.

HENDIADYS, a rhetorical figure in which two words connected by a conjunction are used of a single idea; usually the figure takes the form of two substantives instead of a substantive and adjective, as in the classical example *pateris libamus et auro* (Virgil, *Georgics*, ii. 192), "we pour libations in cups and gold" for "cups of gold."

HENDON, an urban district of Middlesex, England, on the river Brent, 8 m. N.W. of St. Paul's cathedral, London. Pop. (1921) 56,013. The church of St. Mary is mainly Perpendicular, and contains a Norman font. To the north of the village, now a residential suburb of the metropolis, is Mill Hill, with a Roman Catholic Missionary college, opened in 1871, and a public school founded by Nonconformists in 1807. The manor belonged at an early date to the abbot of Westminster.

HENDRICKS, THOMAS ANDREWS (1819-1885), American political leader, vice-president of the United States in 1885, was born near Zanesville, O., on Sept. 7, 1819. He graduated at Hanover college, Hanover, Ind., in 1841, and began in 1843 a successful career at the bar. Identifying himself with the democratic party, he served in the State house of representatives in 1848, and was a prominent member of the convention for the revision of the State constitution in 1850-51, a representative in Congress (1851-55), commissioner of the U.S. General Land Office (1855-59), a U.S. senator (1863-69), and governor of Indiana (1873-77). From 1868 until his death he was put forward for nomination for the presidency at every national democratic convention save in 1872. Both in 1876 and 1884, after his failure to receive the nomination for the presidency, he was nominated by the democratic convention for vice-president. In 1876, with S. J. Tilden, he lost the disputed election by the decision of the electoral commission, but he was elected with Grover Cleveland in 1884. He died at Indianapolis on Nov. 25, 1885.

HENGEL or **HENGEL**, a town in the province of Overijssel, Holland, and a junction station 5 m. by rail N.W. of Enschede.

Pop. (1926) 30,036. The town is the centre of the flourishing industries of the Twente district. The manufacture of cotton in all its branches is carried on, and there are dye-works and breweries, besides the engineering works of the state railway company.

HENGEST and Horsa, the brother chieftains who led the first Saxon bands which settled in England. They were apparently called in by the British king Vortigern (*q.v.*) to defend him against the Picts. Their landing place is said to have been Ebbsfleet in Kent. Its date is not certainly known, 450–455 being given by the English authorities, 428 by the Welsh (*see* KENT). The settlers of Kent are described by Bede as Jutes (*q.v.*), and there are traces in Kentish custom of differences from the other Anglo-Saxon kingdoms. Hengest and Horsa were given the island of Thanet as a home, but soon quarrelled with their British allies, and gradually acquired what became the kingdom of Kent. In 455 the Saxon Chronicle records a battle between Hengest and Horsa and Vortigern at a place called Aegaeles threp, in which Horsa was slain. Thenceforward Hengest reigned in Kent, together with his son Aesc (Oisc). Both the *Saxon Chronicle* and the *Historia Brittonum* record three subsequent battles, though they disagree as to their issue. There is no doubt, however, that the net result was the expulsion of the Britons from Kent. According to the *Chronicle*, probably based on a lost list of Kentish kings, Hengest died in 488, while his son Aesc continued to reign until 512.

Bede, *Hist. Eccl.* (Plummer, 1896), i. 15, ii. 5; *Saxon Chronicle* (Earle and Plummer, 1899), s.a. 449, 455, 457, 465, 473; Nennius, *Historia Brittonum* (San Marte, 1844), §§ 31, 37, 38, 43–46, 58.

HENGSTENBERG, ERNST WILHELM (1802–1869), German Lutheran divine and theologian, was born at Fröndenberg, Westphalia, on Oct. 20, 1802. He studied at the universities of Bonn and Berlin, and in 1826 became professor extraordinarius and in 1828 professor of theology at Berlin. In July 1827 he started the *Evangelische Kirchenzeitung*, a strictly orthodox journal. In 1830 an anonymous article (by E. L. von Gerlach) appeared in this journal which charged Wilhelm Gesenius and J. A. L. Wegscheider with infidelity and profanity, and advocated the interposition of the civil power, thus giving rise to the *Hallsche Streit*. He died on May 28, 1869.

His principal work is *Christologie des Alten Testaments* (1829–35; 2nd ed., 1854–57; Eng. trans. by R. Keith, 1835–39, also in Clark's "Foreign Theological Library," by T. Meyer and J. Martin, 1854–58). Of his other works, the chief are: *Beiträge zur Einleitung in das Alte Testament* (1831–39, Eng. trans. 1848); *Commentar über die Psalmen* (1842–47; Eng. trans. 1844–48); *Die Offenbarung Johannis erläutert* (1849–51; Eng. trans., 1851–52) and *Das Evangelium Johannis erläutert* (1861–63).

See J. Bachmann's *Ernst Wilhelm Hengstenberg* (3 vols., 1876–92); also his article in Herzog-Hauck, *Realencyklopädie* (1899); and F. Lichtenberger, *Hist. of German Theology in the Nineteenth Century* (1889).

HENKE, HEINRICH PHILIPP KONRAD (1752–1809), German theologian, was born at Hehlen, Brunswick, on July 3, 1752. He studied at Helmstädt, and from 1778 to 1809 he was professor, first of philosophy, then of theology, in that university. He died on May 2, 1809. Henke belonged to the rationalistic school. His principal work (*Allgemeine Geschichte der christl. Kirche*, 6 vols., 1788–1804; 2nd ed., 1795–1806) is commended by F. C. Baur for fullness, accuracy and artistic composition.

HENLE, FRIEDRICH GUSTAV JAKOB (1809–1885), German pathologist and anatomist, was born on July 9, 1809, at Fürth, in Franconia. After studying medicine at Heidelberg and at Bonn, where he took his doctor's degree in 1832, he became prosector in anatomy to Johannes Müller at Berlin. During the six years he spent in that position he published three anatomical monographs on new species of animals and papers on the structure of the lacteal system, the distribution of epithelium in the human body, the structure and development of the hair, the formation of mucus and pus, etc. In 1840 he became professor of anatomy at Zürich, and in 1844 he was called to Heidelberg, where he taught not only anatomy, but physiology and pathology.

About this period he was engaged on his complete system of general anatomy, which formed the sixth volume of the new edition of S. T. von Sömmerring's treatise, published at Leipzig between 1841 and 1844. While at Heidelberg he published a zoological monograph on the sharks and rays, in conjunction with his master, Müller, and in 1846 his famous *Manual of Rational Pathology* began to appear. This book marked the beginning of a new era in pathological study, since in it physiology and pathology were treated, in Henle's own words, as "branches of one science," and the facts of disease were systematically considered with reference to their physiological relations. In 1852 he moved to Göttingen, whence he issued three years later the first instalment of his great *Handbook of Systematic Human Anatomy*, the last volume of which was not published till 1873. During the latter half of his life Henle's researches were mainly histological in character. His investigations embracing the minute anatomy of the blood vessels, serous membranes, kidney, eye, nails, central nervous system, etc. He died at Göttingen on May 13, 1885.

HENLEY, JOHN (1692–1759), English clergyman, commonly known as "Orator Henley," was born on Aug. 3, 1692, at Melton Mowbray, where his father was vicar. He graduated from St. John's College, Oxford, and, after holding various cures, was presented in 1723 to the rectory of Chelmondiston, Suffolk; but residence being insisted on, he resigned, and on July 3, 1726, opened what he called an "oratory" in Newport Market, London, which he licensed under the Toleration Act. In 1729 he transferred the scene of his operations to Lincoln's Inn Fields. Into his services he introduced many peculiar alterations: he drew up a "Primitive Liturgy," in which he substituted for the Nicene and Athanasian creeds two creeds taken from the Apostolical Constitutions; for his "Primitive Eucharist" he made use of unleavened bread and mixed wine; he distributed at the price of one shilling medals of admission to his oratory, with the device of a sun rising to the meridian, with the motto *Ad summa*, and the words *Inveniam viam aut faciam* below. But the most original element in the services was Henley himself, who is described by Pope in the *Dunciad* as

"Preacher at once and zany of his age."

His services were much frequented by the "free-thinkers," and he himself expressed his determination "to die a rational." For some time he edited the *Hyp Doctor*, a weekly paper established in opposition to the *Craftsman*. He died on Oct. 13, 1759.

Henley is the subject of several of Hogarth's prints. His life, professedly written by A. Welsted, but in all probability by himself, was inserted by him in his *Oratory Transactions* (1728). *See* J. Nichols, *History of Leicestershire* 4 vols. (1795–1815); I. Disraeli, *Calamities of Authors*, 2 vols. (1812, new ed. by the Earl of Beaconsfield, 1881).

HENLEY, WILLIAM ERNEST (1849–1903), British poet, critic and editor, was born at Gloucester and educated at the Crypt grammar school where he had the good fortune to have T. E. Brown (*q.v.*) as headmaster for a time. Henley contracted tuberculosis as a child, and one foot had to be amputated. He was placed in Edinburgh infirmary in 1874, to be under Lister's care, and from his bed there he sent to the *Cornhill Magazine* poems in irregular rhythms, describing with poignant force his experiences in hospital. Leslie Stephen, then editor, being in Edinburgh, took Robert Louis Stevenson, another recruit of the *Cornhill*, to see him in hospital. This meeting was the beginning of a famous friendship. In 1877 Henley went to London and began a long and distinguished journalistic career. He edited *London* (1877–82), the *Magazine of Art* (1882–86), and in 1888 became literary editor and in 1889 editor of the *Scots Observer*, transferred to London as the *National Observer*. In this paper appeared Kipling's *Barrack Room Ballads*. In 1880 appeared Henley's own *Book of Verse*, which included the verses written in hospital at Edinburgh, and in 1890 *Views and Reviews*. The criticisms, covering a wide range of authors (except Heine and Tolstoy, all English and French), though wilful and often one-sided were terse, trenchant and picturesque. There followed *The Song of the Sword* (1892), another volume of verse renamed in 1893 *London Voluntaries*; three plays in 1892 written with Stevenson—*Beau Austin*, *Deacon Brodie* and *Admiral Guéna*; and *Macaire* (1895). In 1898 Henley published a collection of his *Poems* and in 1901 a second volume of collected

poetry with the title *Hawthorn and Lavender*. He projected the excellent series of "Tudor Translations" and was engaged on the preface to the Authorized Version of the Bible in that edition when he died. He also prepared, with T. F. Henderson, the centenary edition of the poems of Robert Burns, contributing an essay on the poet to the last volume. He died on July 11, 1903. A portrait-bust of him by Rodin was presented by his widow to the National Portrait Gallery in 1913. His fame rests on his poetry. He excelled alike in his delicate experiments in complicated metres, and the strong impressionism of *Hospital Sketches* and *London Voluntaries*. The influence of Heine may be discerned in these "unrhymed rhythms"; but he was perhaps a truer and more successful disciple of Heine in his snatches of passionate song, the best of which should retain their place in English literature.

See also references in *Stevenson's Letters*; *Cornhill Magazine* (1903) (Sidney Low); *Fortnightly Review* (Aug. 1892) (Arthur Symonds); and for bibliography, *English Illustrated Magazine*, vol. xxix. p. 548.

HENLEY-ON-THAMES, a market town and municipal borough of Oxfordshire, England, on the left bank of the Thames, the terminus of a branch of the Great Western railway, by which it is 35½ m. W. of London, while it is 57½ m. by river. Pop. (1921) 6,836. It is situated at the foot of the Chiltern hills. The river is crossed by a stone bridge of five arches, constructed in 1786. The parish church (Decorated and Perpendicular) possesses a tower of intermingled flint and stone, attributed to Cardinal Wolsey, but more probably erected by Bishop Longland. The grammar school, founded in 1605, is incorporated with a Blue Coat school. Henley is celebrated for the annual Henley Royal Regatta, the principal gathering of amateur oarsmen in England, first held in 1839 and usually taking place in July.

Henley-on-Thames (Hanlegang, Henle, Handley) was a manor of the crown and was granted (1337) to John de Molyns, whose family held it for about 250 years. It is said that members for Henley sat in parliaments of Edward I. and Edward III., but no writs have been found. The town was incorporated in 1570-71. Henley suffered from both parties in the Civil War. William III. on his march to London (1688) rested here and received a deputation from the Lords. The period of prosperity in the 17th and 18th centuries was due to manufactures of glass and malt, and to trade in corn and wool. It is now a centre for market-gardening. The existing Thursday market was granted by a charter of John and the existing Corpus Christi fair by a charter of Henry VI.

HENNA, the Persian name for a small shrub found in India, Persia, the Levant and along the African coasts of the Mediterranean, where it is frequently cultivated. It is the *Lawsonia inermis* of botanists, so called because young trees are spineless, while older ones have the branchlets hardened into spines. It forms a slender shrubby plant of from 8 ft. to 10 ft. high, with opposite lance-shaped smooth leaves, which are entire at the margins, and bears small white four-petalled sweet-scented flowers disposed in panicles. Its Egyptian name is *Khenna*, its Arabic name *Al Khanna*, its Indian name *Mendee*, while in England it is called *Egyptian privet*, and in the West Indies, where it is naturalized, *Jamaica mignonette*.

Henna or Henné is of ancient repute as a cosmetic. This consists of the leaves of the *Lawsonia* powdered and made up into a paste; this is employed by the Egyptian women, and also by the Mohammedan women in India, to dye their finger-nails and other parts of their hands and feet an orange-red colour, which is considered to add to their beauty. The colour lasts for three or four weeks, when it requires to be renewed. It is moreover used for dyeing the hair and beard, and even the manes of horses; and the same material is employed for dyeing skins and morocco-leather a reddish-yellow, but it contains no tannin. The practice of dyeing the nails was common amongst the Egyptians, and not to conform to it would have been considered indecent. It has descended from very remote ages, as is proved by the evidence afforded by Egyptian mummies, the nails of which are most commonly stained a reddish hue. Henna is also said to have been held in repute amongst the Hebrews, being considered to be the plant referred to as camphire in the Bible (Song of Solomon i. 14, iv. 13). "The custom of dyeing the nails and palms of the hands and soles of the

feet of an iron-rust colour with henna," observes Dr. J. Forbes Royle, "exists throughout the East from the Mediterranean to the Ganges, as well as in northern Africa. In some parts the practice is not confined to women and children, but is also followed by men, especially in Persia. In dyeing the beard the hair is turned to red by this application, which is then changed to black by a preparation of indigo. In dyeing the hair of children, and the tails and manes of horses and asses, the process is allowed to stop at the red colour which the henna produces." Mohammed, it is said, used henna as a dye for his beard, and the fashion was adopted by the caliphs.

The preparation of henna consists in reducing the leaves and young twigs to a fine powder, catechu or lucerne leaves in a pulverized state being sometimes mixed with them. When required for use, the powder is made into a pasty mass with hot water, and is then spread upon the part to be dyed, where it is generally allowed to remain for one night. The distilled water from the flowers is used as a perfume.

HENNEBONT, a town of western France, in the department of Morbihan, 6 m. N.E. of Lorient. Pop. (1926) 6,243. Hennebont is famed for the resistance which it made, under the widow of Jean de Montfort, when besieged in 1342 by the armies of Philip of Valois and Charles of Blois during the War of the Succession in Brittany (see BRITTANY). It is near the mouth of the Blavet, which divides it into the Ville Close, the mediaeval military town, and the Ville Neuve on the left bank and the Vieille Ville on the right bank. The Villa Close, surrounded by ramparts and entered by a massive gateway flanked by machicolated towers, consists of narrow streets bordered by 16th and 17th century houses. The Ville Neuve, nearer the river, developed during the 17th century. The Gothic church of Notre-Dame de Paradis (16th century) has a tower with ornamented stone spire. There are scanty remains of the old fortress. Hennebont has a small but busy river-port accessible for small vessels. Hennebont is a market town for grain, cheese and agricultural produce; it has an important foundry manufacturing tin plate. Other industries are tanning, distilling and the manufacture of earthenware. Granite is worked in the neighbourhood.

HENNEPIN, LOUIS (1640- ?), Belgian missionary and explorer, was born in Ath, Belgium, about 1640. While quite young he joined the Franciscan order. In 1675 he went to Canada in company with a Recollet mission, crossing in the same ship with La Salle and Bishop De Laval. From Quebec, Hennepin carried on his missionary work (in 1677 among the Iroquois). The next year (1678) he accompanied La Salle on his expedition to the West. They reached the present site of Peoria (Jan. 1, 1680), when La Salle was compelled to return to Ft. Frontenac for supplies; Hennepin and the remainder of the party were despatched to explore the upper Mississippi. They reached the falls of St. Anthony, where the modern Minneapolis stands, in July 1680, and were soon afterwards captured by Sioux Indians. Hennepin was rescued in June 1681 by Graysolon du Lhut (Duluth) and went to Quebec. In 1683 Hennepin was in France where he published a *Description de la Louisiane*, a full account of his exploits, but in 1697, La Salle having died, he brought out a revised copy of his earlier book, *Nouvelle Découverte*, in which he claimed to have explored the Mississippi to its mouth. This bold assumption was soon discredited and Hennepin's otherwise valuable contributions to the history of New France and American ethnology are looked upon with suspicion. He incurred the displeasure of his order by refusing to return to America and as a result his last years were spent in obscurity.

See J. G. Shea, *A Description of Louisiana by Father Louis Hennepin* (1880); "Father Louis Hennepin" in vol. iv. of Justin Winsor's *Narrative and Critical History of America* (1889). A complete bibliography of Hennepin's works is found in C. R. Remington's *The Shipyard of the Griffin* (Buffalo, 1891).

HENNER, JEAN JACQUES (1829-1905), French painter, was born on March 5, 1829, at Bernweiler (Alsace), the son of a peasant. He first studied at Altkirch in 1841. In 1844 he worked at Strasbourg under Gabriel Guérin, and in 1846 he entered the Ecole des Beaux Arts in Paris under M. Drolling. He returned to his native place for two years in 1855 to paint portraits, a col-

lection of which are now at the Sundgau Museum at Altkirch. In 1857 he joined the studio of Picot in Paris, and took the Prix de Rome with a painting of "Adam and Eve finding the Body of Abel" (1858). At Rome he was guided by Flandrin, and, among other works, painted four pictures for the gallery at Colmar. He first exhibited at the Salon in 1863 a "Bather Asleep," and subsequently contributed more or less regularly until 1903. He died in Paris on July 23, 1905. He is best known for his paintings of nude figures posed in ideal landscape enveloped in a golden clare-obscure suggestive of Correggio. He also painted a number of portraits. A self portrait is in the Uffizi at Florence. There are nine pictures by him in the Luxembourg gallery and 31 in the Palais des Beaux Arts (Salle Henner). In 1924 the Henner museum, comprising about 200 paintings, drawings and lithographs, bequeathed by the artist's nephew, was inaugurated in the Avenue de Villiers in Paris.

HENOGAMY, a term used to denote the custom by which one, and only one, member of a family or stock is permitted to marry, or is required to marry according to definite rules which are not binding on other members of the family. Thus, among the Nabuthiri Brahmins of Malabar "the eldest son alone marries. The accepted practice, as well as the recognized principle among them, seems to be in consonance with the directions expounded by Manu, viz., immediately on the birth of his firstborn male child, a man is the father of a son, and is free from the debt to the Manes. That son is, therefore, worthy to receive the whole estate. That son alone, on whom he throws his debt, is begotten for (the fulfilment of) the law. And the next they consider the offspring of desire. . . . Should a Nabuthiri eldest son die, the next marries and so on." (E. Thurston, *Tribes and Castes of Southern India*, 1909, vol. v., p. 175.)

This custom, it is observed, has long been in force to keep the family property intact and to prevent its disintegration by partition which the marriage of the younger sons might necessitate (A. N. Krishna Iyer, *The Cochin Tribes and Castes*, 1912, vol. ii., p. 183). Polygamy "is often indulged in by the Nabuthiris, owing partly to their desire to have a son to perform funeral and other ceremonies for the spirits of the departed, and partly to dispose of the superfluous number of girls." (*Ibid.*, p. 210.) The younger males contract alliances with Nayar women. Their children belong to the *Tarwad*, a matrilineal group of their mothers and pollute their Brahmin fathers. This dislocation of the social order extends far down in Malabar society, and is ultimately traceable to the practice of henogamy among the patrilineal Brahmins. The belief in direct and specific reincarnation which is embodied in the teaching of Manu is connected with customs in the Punjab, where "the position of the firstborn is probably due to the fact that, if a son, his father is born again in him, so that the father is supposed to die at his birth, and in certain Khatri sections, e.g., the Kochhar, his funeral rites are actually performed—in the fifth month of the mother's pregnancy. Probably herein lies the explanation of the *dev-kaj*, or divine nuptials, a ceremony which consists in a formal re-marriage of the parents after the birth of their first son" (*Punjab. Census Report*, 1901, part I. p. 215).

Among the matrilineal Garos (*q.v.*) the youngest daughter is reserved for marriage with her father's brother's son, after he has married her own mother who, under the dual system, is also his paternal aunt (A. Playfair, *The Garos*, 1909, p. 67; *Assam Census Report*, 1891, p. 229). The elder daughters make their own arrangements for marriage.

There are other instances in India and elsewhere of rules by which special status—as regards inheritance and succession—is conferred by marriage between specified persons, as if one mode or set of rites gave peculiar dignity and validity. These devices mark decisively a change from a social order in which inheritance and succession are determined by the principle of social equivalence, as in the levirate (*q.v.*) or sororate (*q.v.*), which is expressed in terms of a classificatory system, to that order in which one line is selected, one son preferred, for transmission. The economic results which in history have accrued from the emergence of the principle of unilinealism have been, and still are, considerable. The custom of henogamy, if extended to cover the

case where special rites and conditions are used for the marriage of the eldest son, is of wide occurrence, and the survival in India of the strict logical form has, therefore, special interest.

HENRI, ROBERT (1865–1929). American painter, was born in Cincinnati, O., in 1865. In 1886 he entered the Pennsylvania Academy of Fine Arts, Philadelphia. Proceeding to Paris in 1888, he studied at Julien's and the École des Beaux Arts and visited Spain and Italy. Returning to the United States he became in 1891 an instructor at the Women's School of Design, Philadelphia. From 1896 to 1900 he was again in Paris, and exhibited at the Salon. During an extremely active life as a painter, he found time to teach and exercised considerable influence by the vigour and independence of his style as a portrait painter. From 1915–23 he taught at the Art Students' League, New York.

Of his works, "La Neige" was purchased in 1899 for the Luxembourg in Paris; "The Equestrian," Carnegie Art Institute, Pittsburgh; "Young Woman in Black," Art Institute, Chicago; "The Spanish Gypsy," Metropolitan Museum, New York, and "Indian Girl in White Ceremonial Blanket," in the Corcoran Gallery, Washington, D.C. He died in New York city, July 12, 1929.

HENRIETTA MARIA (1609–1666), queen of Charles I. of England, daughter of Henry IV. of France, was born on Nov. 25, 1609. The first serious overtures for her hand were made in the spring of 1624, on behalf of Charles, prince of Wales. Her brother, Louis XIII., consented to the marriage on the condition that the English Roman Catholics were relieved from the operation of the penal laws. She was married on May 11, 1625, in Paris, the duke of Chevreuse acting as proxy for Charles, who was now king, and she set out for England in June.

The early years of their married life were unhappy. Charles soon found an excuse for breaking his promise to relieve the English Catholics. His young wife was deeply offended, and the favourite Buckingham stirred the flames of his master's discontent. After the assassination of Buckingham (1628) the barrier between the married pair was broken down, and Charles caused much discontent by his favourable treatment of the Catholic subjects whom he had formerly persecuted. The children of the marriage were Charles II. (b. 1630), Mary, princess of Orange (b. 1631), James II. (b. 1633) Elizabeth (b. 1636), Henry, duke of Gloucester (b. 1640), and Henrietta, duchess of Orleans (b. 1644).

For some years Henrietta Maria's chief interests lay in the amusements of a brilliant court, and she took no part in politics. Her participation in the private rehearsals of the *Shepherd's Pastoral*, written by her favourite Walter Montague, probably drew down upon her the savage attack of Prynne. Her co-religionists found little aid from her till 1636. She had then recently opened a diplomatic communication with the see of Rome, and under the influence of a papal agent, a Scotsman named George Conn, accredited to her, thwarted Laud's proclamation against the Catholic recusants.

When the Scottish troubles broke out in 1639, she raised money from her fellow-Catholics to support the king's army on the borders. During the session of the Short Parliament in the spring of 1640, the queen urged the king to oppose himself to the House of Commons in defence of the Catholics. She was at the time generally believed to be the instigator of the Army Plot, in which the English people saw only an attempt to establish Catholic supremacy, but she was probably acting on the suggestion of her adviser Henry Jermyn. She threw herself heart and soul into the schemes for rescuing Strafford and coercing the parliament, and the impeachment of the five members on the charge of treason was brought about by her influence over the king.

In Feb. 1642 the queen went to the Continent to try to raise support in arms and money. In Feb. 1643 she landed at Bridlington quay with a large sum of money, but no foreign troops. She placed herself at the head of a force of loyalists, and in spite of some opposition marched through England to join the king near Oxford, which they entered together on July 14. By July 1644, however, her position had become so insecure that she was persuaded again to take refuge in France, where she received a pension of 12,000 crowns a month from the queen regent. As long

as her husband was alive the queen never ceased to make plans and raise funds to encourage his resistance, and she continued to hope for success until she heard of his execution in 1649.

She brought up her youngest child Henrietta in her own faith, but failed to induce her youngest son, the duke of Gloucester, to take the same course. When after the Restoration (Oct. 1660) she returned to England, she found that she had no place in the new world. She received from parliament a grant of £30,000 a year in compensation for the loss of her dower-lands, and the king added a similar yearly sum. In Jan. 1661 she returned to France to be present at the marriage of her daughter Henrietta to the duke of Orleans. She set out again for England in July 1662, and took up her residence once more at Somerset House. In 1665 she returned to France, and died on August 31, 1666, at Colombes, not far from Paris.

See I. A. Taylor, *The Life of Queen Henrietta Maria* (1905).

HENRY, "prince of the house" (Fr. *Henri*; Span. *Enrique*; Ger. *Heinrich*). The name of many European sovereigns.

HENRY (HENRY BENEDICT MARIA CLEMENT STUART) (1725–1807), usually known as Cardinal York, the last prince of the royal house of Stuart, younger son of James Stuart, was born in the Palazzo Muti at Rome on March 6, 1725. He was created duke of York by his father soon after his birth, and by this title he was always alluded to by Jacobite adherents of his house. In support of the Young Pretender's campaign in Scotland, Henry was despatched in the summer of 1745 to France, where he was placed in nominal command of French troops at Dunkirk, with which the marquis d'Argenson had some idea of invading England. Seven months after Charles's return from Scotland Henry, who had joined his brother in Paris, secretly left for Rome and, with his father's approval, but to his brother's disgust, was created a cardinal deacon under the title of the cardinal of York by Pope Benedict XIV. on July 3, 1747. In the following year he was ordained priest, and nominated arch-priest of the Vatican Basilica. In 1759 he was consecrated archbishop of Corinth *in partibus*, and in 1761 bishop of Frascati (the ancient Tusculum) in the Alban Hills near Rome, where he founded an ecclesiastical seminary. In 1763 he became vice-chancellor of St. Peter's. Henry Stuart held sinecure benefices in France, Spain and Spanish America, so that he became one of the wealthiest churchmen of the period, his annual revenue being said to amount to £30,000 sterling. On the death of his father, James Stuart, Henry tried unsuccessfully to induce Pope Clement XIII. to acknowledge his brother Charles as legitimate king of Great Britain. On Charles's death in 1788 Henry issued a manifesto asserting his hereditary right to the British crown. At the outbreak of the French Revolution he lost two rich French livings and his pension from Spain, and in Feb. 1798, at the approach of the invading French forces, he was forced to fly to Naples, whence he sailed to Messina. At this time he disposed of his family heirlooms to help the pope raise the tribute demanded by Napoleon. From Messina he proceeded by sea in order to be present at the expected conclave at Venice, where he arrived in the spring of 1799, aged, ill and almost penniless. George III., on the recommendation of Prince Augustus Frederick, duke of Sussex, gave a pension of £4,000 a year to the last of the royal Stuarts. Henry received this assistance gratefully, and subsequently left by his will certain British crown jewels in his possession to the prince regent. In 1800 Henry was able to return to Rome, and in 1803, being senior cardinal bishop, he became *ipso facto* dean of the sacred college and bishop of Ostia and Velletri. He died at Frascati on July 13, 1807, and was buried in the *Grotte Vaticane* of St. Peter's in an urn bearing the title "Henry IX."; he is also commemorated in Canova's well-known monument to the royal Stuarts (see JAMES). The Stuart archives, once the property of Cardinal York, were presented by Pope Pius VII. to the prince regent, who placed them in the royal library at Windsor Castle.

See B. W. Kelly, *Life of Cardinal York*; H. M. Vaughan, *Last of the Royal Stuarts*; A. Shield, *Henry Stuart, Cardinal of York, and his Times* (1908); T. F. Henderson, *The Royal Stuarts* (1914).

HENRY II. (973–1024), surnamed the "Saint," Roman emperor, son of Henry II., the Quarrelsome, duke of Bavaria,

and Gisela, daughter of Conrad, king of Burgundy, or Arles (d. 993), and great-grandson of the German king Henry I., was born on May 6, 973, and was educated at Hildesheim and at Regensburg. He became duke of Bavaria on his father's death in 995, and about 1001 married Kunigunde (d. 1037), daughter of Siegfried, count of Luxembourg. When Otto III. died childless in 1002, Henry was chosen German king by the Franks and Bavarians on June 7, 1002, and subsequently crowned by Willigis, archbishop of Mainz. He purchased the allegiance of the Thuringians and the Saxons; and when shortly afterwards the nobles of Lorraine did homage and Hermann of Swabia, his rival, submitted, he was generally recognized as king. An incipient war with Boleslaus I., the Great, king of Poland, who had extended his authority over Meissen and Lusatia, seized Bohemia, and allied himself with some discontented German nobles, including the king's brother, Bruno, bishop of Augsburg, was abandoned in favour of an expedition into Italy, where Arduin, margrave of Ivrea, had been elected king. Crossing the Alps Henry met with no resistance from Arduin, and in May 1004 was crowned king of the Lombards at Pavia. He then freed Bohemia from the rule of the Poles, led an expedition into Friesland, and compelled Boleslaus to sue for peace in 1005. A struggle with Baldwin IV., count of Flanders, in 1006 and 1007 was followed by trouble with the king's brothers-in-law, Dietrich and Adalbero of Luxembourg, who had seized respectively the bishopric of Metz and the archbishopric of Trier (Treves). In 1013, peace was made with Boleslaus and later in the year, the king went to Rome where, having recognized Benedict VIII. as the rightful pope, he was crowned emperor on Feb. 14, 1014. But the struggle with the Poles broke out afresh, and in 1015 and 1017 Henry led formidable armies against Boleslaus. On Jan. 30, he made peace at Bautzen, Boleslaus retaining Lusatia. As early as 1006 Henry had concluded a succession treaty with his uncle Rudolph III., the childless king of Burgundy, or Arles; but when Rudolph desired to abdicate in 1016 Henry's efforts to secure possession of the crown were resisted by the nobles. In 1020 the emperor was visited at Bamberg by Pope Benedict, in response to whose entreaty for assistance against the Greeks of southern Italy he crossed the Alps in 1021 for the third time. With the aid of the Normans he crippled the Greeks, but was compelled by pestilence among his troops to return to Germany in 1022. He died on July 13, 1024 at Grona near Göttingen.

Henry was an enthusiast for church reform, and under the influence of his friend Odilo, abbot of Cluny, sought to further the principles of the Cluniacs, and seconded the efforts of Benedict VIII. to prevent clerical marriage and the sale of spiritual dignities. Nevertheless he appointed bishops without the formality of an election, and sometimes attacked clerical privileges. He held numerous diets and issued frequent ordinances for peace, but feuds among the nobles were common, and the frontiers of the empire were insecure. Henry, who was the last emperor of the Saxon house, was the first to use the title "King of the Romans." He was canonized in 1146 by Eugenius III.

HENRY III. (1017–1056), surnamed the "Black," Roman emperor, only son of the emperor Conrad II., and Gisela, widow of Ernest I., duke of Swabia, was born on Oct. 28, 1017, designated as his father's successor in 1026, and crowned German king at Aix-la-Chapelle on April 14, 1028. In 1027 he was appointed duke of Bavaria, where he had been educated under Bruno, bishop of Augsburg and under Egilbert, bishop of Freising. In 1032 he took part in a campaign in Burgundy; in 1033 led an expedition against Ulalrich, prince of the Bohemians; and in June 1036 married Gunhilda, afterwards called Kunigunde, daughter of Canute, king of Denmark and England. In 1038 the emperor

formally handed over to him the kingdom of Burgundy, or Arles, and appointed him duke of Swabia.

When Conrad died in June 1039, Henry became sole ruler of the empire. A struggle soon broke out with Bretislaus, prince of the Bohemians, who revived the idea of an independent Slavonic state, and conquered various Polish towns. After suffering two defeats in 1040, in the following year Henry was able to compel Bretislaus to sue for peace and to do homage for Bohemia. In 1042 he received the homage of the Burgundians and his attention was then turned to the Hungarians, who had driven out their king Peter, and set up one Aba Samuel, or Ovo, who attacked eastern Bavaria. During 1043-45 Henry restored Peter, and brought Hungary completely under the German king.

In 1038 Queen Kunigunde had died and in 1043 the king married Agnes, daughter of William V., duke of Guienne. In 1044 Gothelon (Gozelo), duke of Lorraine, died, and some disturbance arose over Henry's refusal to grant the whole of the duchy to his son Godfrey, called the Bearded. Godfrey took up arms, but after a short imprisonment was confirmed in the possession of Upper Lorraine in 1046 which, however, he failed to secure. About this time, the rival popes were deposed, and the king secured the election of Suidger, bishop of Bamberg, who crowned Henry emperor on Dec. 25, 1046. He was immediately recognized by the Romans as *Patricius*, an office which carried with it at this time the right to appoint the pope. Supreme in church and state alike, ruler of Germany, Italy and Burgundy, overlord of Hungary and Bohemia, Henry occupied a commanding position. He made a victorious progress in southern Italy, where he restored Pandulph IV. to the principality of Capua, and asserted his authority over the Normans in Apulia and Aversa. Returning to Germany in 1047 he appointed two popes, Damasus II. and Leo IX., in quick succession, and faced a threatening combination in the west of the empire, where Godfrey of Lorraine was again in revolt, and with Baldwin V., count of Flanders and Dirk IV., count of Holland, who had previously caused trouble, was ravaging the emperor's lands in Lorraine. Assisted by the kings of England and Denmark, Henry subdued the rebels in 1050. Godfrey was deposed; but Baldwin in 1054 again revolted.

Meanwhile a reaction against German influence had taken place in Hungary. King Peter had been replaced in 1046 by Andreas I., and inroads into Bavaria followed. A brief peace was secured in 1053, but the emperor, occupied elsewhere, soon lost his authority in the east. On pope Leo's death, Henry nominated Gebhard, bishop of Eichstätt, to the vacant chair. In 1055 the emperor went a second time to Italy, where his authority was threatened by Godfrey of Lorraine, who had married Beatrice, widow of Boniface III., margrave of Tuscany, and was ruling her vast estates. Godfrey fled, however, on the appearance of Henry, who only remained a short time in Italy, during which he granted the duchy of Spoleto to the pope. During his absence, the deposed Conrad III., duke of Bavaria, Welf, duke of Carinthia, and Gebhard III., bishop of Regensburg, formed an unsuccessful conspiracy against him. The emperor died at Bodfeld on Oct. 5, 1056. He was a peace-loving prince, who favoured church reform and sought to suppress private warfare. But he alienated the sympathies of the nobles as a class, and, by allowing the southern duchies to pass into other hands, restored a power which was not always friendly to the royal house. Henry was a patron of learning, a founder of schools, and completed cathedrals at Spire, Worms and Mainz.

HENRY IV. (1050-1106), Roman emperor, son of the emperor Henry III. and Agnes, daughter of William V., duke of Guienne, was born on Nov. 11, 1050, chosen German king at

Tribur in 1053, and crowned at Aix-la-Chapelle on July 17, 1054. In 1055 he was appointed duke of Bavaria, and on his father's death in 1056 inherited the kingdoms of Germany, Italy and Burgundy. These territories were governed in his name by his mother, who was compelled in 1062 to hand over her control to Anno, archbishop of Cologne, and to Adalbert, archbishop of Bremen. In March 1065 Henry was declared of age, and in the following year married Bertha, daughter of Otto, count of Savoy.

In 1069 the king led expeditions against the Liutii, and against Dedo or Dedi II., margrave of a district east of Saxony; and soon afterwards quarrelled with Rudolph, duke of Swabia, and Berthold, duke of Carinthia. His struggle with Otto of Nordheim, duke of Bavaria, who was accused in 1070 of being privy to a plot to murder the king, ended in the duke's submission in 1071. Henry aroused the hostility of the Thuringians by supporting Siegfried, archbishop of Mainz, in his efforts to exact tithes from them, and the enmity of the Saxons by ordering a restoration of all crown lands in Saxony, by ravaging the country to supply the needs of his courtiers, and by holding its duke Magnus a prisoner. In 1073 the Thuringians joined the Saxons, and the war, which lasted with slight intermissions until 1088, exercised a potent influence upon Henry's fortunes elsewhere (*see* SAXONY). For Henry's dispute with Hildebrand (Pope Gregory VII.), his excommunication and his famous visit to Canossa *see* GREGORY VII.

Henry left Italy to find that in his absence Rudolph, duke of Swabia, had been chosen German king; and although Hildebrand had taken no part in this election, Henry sought to prevent the pope's journey to Germany, and tried to recover his former position. Though supported by most of the German bishops and by the Lombards and recognized in Burgundy, Bavaria and Franconia, Henry suffered defeat at Mellrichstadt in 1078 and at Flarchheim in 1080. Gregory's attitude remained neutral, in spite of appeals from both sides, until March 1080, when he again excommunicated Henry. At Henry's initiative, Gregory was declared deposed on three occasions, and an anti-pope was elected in the person of Wibert, archbishop of Ravenna, who took the name of Clement III.

The death of Rudolph, the rival German king, in Oct. 1080, left the king at liberty to go to Italy early in 1081. He found considerable support in Lombardy; placed Matilda, marchioness of Tuscany, the faithful friend of Gregory, under the imperial ban; took the Lombard crown at Pavia; and secured the recognition of Clement by a council. After two unsuccessful attacks, he took Rome in 1082, and a treaty was concluded with the Romans, who agreed that the quarrel between king and pope should be decided by a synod, and secretly bound themselves to induce the pope to crown Henry as emperor, or to choose another pope. The synod was a failure, and in March 1084 Gregory was declared deposed and Clement was recognized by the Romans. On March 31, 1084 Henry was crowned emperor by Clement, and received the patrician authority. His next step was to attack the fortresses still in the hands of the pope, but the advance of Robert Guiscard, duke of Apulia, compelled him to return to Germany.

Meanwhile the German rebels had chosen a fresh anti-king, Hermann, count of Luxemburg. In 1086 Henry was defeated near Würzburg, but in 1088 Hermann abandoned the struggle and the emperor was generally recognized in Saxony. Although Henry's power was in the ascendent, a few powerful nobles adhered to the cause of the new pope, Urban II. Among them was Welf, son of the deposed duke of Bavaria, whose marriage with Matilda of Tuscany rendered him formidable. The emperor accordingly returned to Italy in 1090, where Mantua and Milan were taken, and Pope Clement was restored to Rome.

Henry's first wife had died in 1087, and in 1089 he had married a Russian princess Praxedis, afterwards called Adelaide. Her conduct soon aroused his suspicions, and his own eldest son, Conrad, who had been crowned German king in 1087, was thought to be a partner in her guilt. Adelaide fled to Henry's enemies and brought charges against him; and the papal party induced Conrad to desert his father and to be crowned king of Italy at Monza in 1093. After five years of inactivity Henry returned to Germany where his position was stronger than ever. Welf had submitted

and had been restored to Bavaria; the diet assembled at Mainz in 1098 declared Conrad deposed, and chose the emperor's second son, Henry, afterwards the emperor Henry V., as German king, and the crusade of 1096 had freed Germany from many turbulent spirits. But the younger Henry, in 1104, encouraged by the adherents of the pope, declared he owed no allegiance to an excommunicated father. Saxony and Thuringia were soon in arms and in 1105, the emperor became a prisoner in the hands of his son. A diet at Mainz in December compelled him to abdicate, but contrary to the conditions, he was detained at Ingelheim and denied his freedom. Escaping to Cologne, he entered into negotiations with England, France and Denmark, and was engaged in collecting an army when he died at Liège on Aug. 7, 1106.

After a licentious youth, Henry displayed much diplomatic ability, and his abasement at Canossa may fairly be regarded as a move of policy to weaken the pope's position at the cost of a personal humiliation to himself. He was a friend of the lower orders, was capable of generosity, and showed considerable military skill. Unfortunate in the troubles with which he had to contend, he ably resisted the pretensions both of the papacy and of the ambitious feudal lords of Germany.

Mediaeval Hist.*, vol. 5.

HENRY V. (1081-1125), Roman emperor, son of the emperor Henry IV., was born on Jan. 8, 1081, and after the deposition of his elder brother, the German king Conrad (d. 1101), was chosen as his successor in 1098. In spite of his oath to take no part in the business of the empire during his father's lifetime, Henry was induced by his father's enemies to revolt in 1104, and some of the princes did homage to him at Mainz in Jan. 1106. In August of the same year the elder Henry died, when his son became sole ruler. In 1107 a campaign to restore Bořivoj II. to the dukedom of Bohemia was partially successful, and in the year following the king led his forces into Hungary, where he failed to take Pressburg. In 1109 he was unable to compel the Poles to renew their accustomed tribute, but in 1110 he succeeded in securing the dukedom of Bohemia for Ladislaus I.

The main interest of Henry's reign centres in the controversy over lay investiture which had been thrice prohibited by Paschal II. In 1110 Henry went to Italy with a large army, and at Sutri concluded an arrangement with Paschal by which he renounced the right of investiture in return for a promise of coronation, and the restoration to the empire of all lands given by kings, or emperors, to the German church since the time of Charlemagne. The king presented himself at St. Peter's on Feb. 12, 1111, for his coronation and the ratification of the treaty. The words commanding the clergy to restore the fiefs of the Crown to Henry were read amid a tumult of indignation, whereupon the pope refused to crown the king, who in return declined to renounce the right of investiture. Henry then left the city carrying the pope with him; and Paschal's failure to obtain assistance drew from him a confirmation of the king's right of investiture and a promise to crown him emperor.

In 1112 Lothair, duke of Saxony, rose against Henry, but was easily quelled. In 1113, however, a quarrel over the succession to the counties of Weimar and Orlamünde gave occasion for a fresh outbreak on the part of Lothair, whose troops were defeated at Warnstädt. Having been married in 1114 to Matilda, or Maud, daughter of Henry I. of England, the emperor was con-

fronted with a further rising, initiated by the citizens of Cologne, who were soon joined by the Saxons and others. Henry's forces were defeated at Welfesholz in 1115, and complications in Italy compelled him to leave Germany to the care of Frederick II. of Hohenstaufen, duke of Swabia, and his brother Conrad. After the departure of Henry from Rome in 1111 a council declared the privilege of lay investiture, which had been extorted from Paschal, to be invalid, and Guido, archbishop of Vienne, excommunicated the emperor, but the pope refused to ratify this sentence. The quarrel entered upon a new stage in 1115 when Matilda, daughter and heiress of Boniface, margrave of Tuscany, died leaving her vast estates to the papacy. Crossing the Alps in 1116, Henry took possession of Matilda's lands. By this time Paschal had withdrawn his consent to lay investiture and the excommunication had been published. The pope was compelled to fly and the emperor was crowned a second time by Burdinas, archbishop of Braga. Paschal was succeeded by Gelasius II. in Jan. 1118, but Henry secured the election of an antipope who took the name of Gregory VIII. Finally in the concordat of Worms (Sept. 1122) Henry renounced the right of investiture with ring and crozier, recognized the freedom of election of the clergy and promised to restore all church property. The new pope Calixtus II. agreed to allow elections to take place in presence of the imperial envoys, and the investiture with the sceptre to be granted by the emperor as a symbol that the estates of the church were held under the Crown. Henry was received again into the communion of the church, after he had abandoned his nominee, Gregory, to defeat. The emperor's concluding years were occupied with a campaign in Holland, and with a quarrel over the succession to the margraviate of Meissen. In 1124 he led an expedition against King Louis VI. of France and turned his arms against the citizens of Worms. He died at Utrecht on May 23, 1125.

HENRY VI. (1165-1197), Roman emperor, son of the emperor Frederick I. and Beatrix, daughter of Renaud III., count of upper Burgundy, was educated under Conrad of Querfurt, afterwards bishop of Hildesheim and Würzburg. Chosen German king at Bamberg in June 1169, he was crowned at Aix-la-Chapelle on Aug. 15, 1169, and invested with lands in Germany in 1179. In 1184 his father sought to procure his coronation from Pope Lucius III., but the pope refused because of the marriage arranged between Henry and Constance, daughter of the late king of Sicily, Roger I., a step which threatened to unite Sicily with Germany. This marriage took place at Milan in Jan. 1186, and soon afterwards Henry was crowned king of Italy. Having been recognized by the pope as Roman emperor elect, Henry returned to Germany, where a campaign against Henry the Lion, duke of Saxony, was followed by a peace made at Fulda in July 1190.

A promise of his coronation from Pope Clement III. led Henry to cross the Alps in the winter of 1190. He purchased the support of the cities of northern Italy, but on reaching Rome found Clement was dead and his successor, Celestine III., disinclined to carry out the coronation. However, the strength of the German army and a treaty made between the king and the Romans induced him to crown Henry on April 14, 1191. Meanwhile a party in Sicily had chosen Tancred, an illegitimate son of Roger, son of King Roger II., as king. Henry marched to Naples, but was compelled to raise the siege and return to Germany. There the Welfs and their earlier opponents were united against the emperor, vacancies in various bishoprics added to the confusion, and Henry was suspected of being implicated in the murder of Albert, bishop of Liège. His salvation came from the captivity of Richard I., king of England, and the skill with which he used this event to make peace with his foes. When Henry the Lion came to terms in March 1194, order was restored to Germany.

In the following May, Henry went again to Italy, where Pope Celestine had espoused the cause of Tancred. When he reached Sicily he found Tancred dead, and, meeting with little resistance, entered Palermo, where he was crowned king on Dec. 25, 1194. Leaving his wife, Constance, as regent, he returned to Germany in June 1195.

Having established his position in Germany and Italy, Henry began to cherish ideas of universal empire. Richard of England had already owned his supremacy, and declaring he would compel the king of France to do the same Henry sought to stir up strife between France and England. Nor did the Spanish kingdoms escape his notice. Tunis and Tripoli were claimed, and when the eastern emperor, Isaac Angelus, asked his help, he demanded in return the cession of the Balkan peninsula. The kings of Cyprus and Armenia asked for investiture at his hands. To complete his scheme two steps were necessary, a reconciliation with the pope and the recognition of his young son, Frederick, as his successor in the empire. The first was easily accomplished; the second was more difficult.

Henry met the princes at Worms in Dec. 1195 and by threats or negotiations won the consent of about 50 of them; but though the diet which met at Würzburg in April 1196 agreed to the scheme, the vigorous opposition of Adolph, archbishop of Cologne, and others rendered it inoperative. In June 1196 Henry went again to Italy to persuade the pope to crown his son who had been chosen king of the Romans at Frankfurt. Celestine refused, and the emperor then went to the south, where the oppression of his German officials had caused an insurrection, which was put down with terrible cruelty. At Messina on Sept. 28, 1197, Henry died from a cold caught whilst hunting.

Henry's poems appeared in F. H. von der Hagen's *Minnesinger* (Leipzig, 1838). The chief authorities for his life are Otto of Freising, *Chronicon*, continued by Otto of St. Blasius; Godfrey of Viterbo, *Gesta Friderici I. and Gesta Heinrici VI.*; Giselbert of Mons, *Chronicon Hanoniense*, all of which appear in the *Monum. Germ. hist. Scriptores*, Bde. xx., xxi., xxii. (1826-92). See also W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit*, Bd. iv. (Brunswick, 1877); T. Toeche, *Kaiser Heinrich VI.* (Leipzig, 1867); H. Bloch, *Forschungen zur Politik Kaiser Heinrichs VI.* (1892); K. A. Kneller, *Des Richard Löwenherz deutsche Gefangenschaft* (Freiburg, 1893); F. Gerlich, *Das Testament Heinrichs VI.* (1907); V. Pfaff, *Kaiser Heinrichs VI. höchstes Angebot an die römische Kurie, 1196* (1927), and *Camb. Mediaeval Hist.* vol. 5.

HENRY VII. (c. 1269-1313), Roman emperor, son of Henry III., count of Luxemburg, passed his early days under French influences. In 1288 he succeeded his father, and four years later married Margaret (d. 1311), daughter of John I., duke of Brabant. After the death of the German king, Albert I., he was elected to the vacant throne on Nov. 27, 1308. The Rhenish archbishops were pacified by the restoration of the Rhine tolls, negotiations were begun with Philip IV., king of France, and with Robert, king of Naples, and the Habsburgs were confirmed in their possessions. At this time Bohemia was ruled by Henry V., duke of Carinthia, but the prevailing disorder induced some of the Bohemians to offer the crown, together with the hand of Elizabeth, daughter of the late king Wenceslas II., to John, the son of the German king. Henry accepted the offer, and in Aug. 1310 John was invested with Bohemia and his marriage was celebrated.

Meanwhile Henry had crossed the Alps, with the hope of reuniting Germany and Italy, and of restoring the empire of the Hohenstaufen. Having entered Milan he placed the Lombard crown upon his head on Jan. 6, 1311. But trouble soon showed itself. His poverty compelled him to exact money from the citizens; the peaceful professions of the Guelphs were insincere, and Robert, king of Naples, watched his progress with suspicion. Risings took place and, after the capture of Brescia, Henry marched to Rome only to find the city in the hands of the Guelphs and the troops of King Robert. The king, unable to obtain possession of St. Peter's, was crowned emperor on June 29, 1312, in the church of St. John Lateran by some cardinals who declared they acted under compulsion. Failing to subdue Florence, the emperor allied himself with Frederick III., king of Sicily, and, with the Venetians, set out to attack Robert of Naples. On the march he was taken ill, and died at Buonconvento near

Siena on Aug. 24, 1313. Henry was hailed by Dante as the deliverer of Italy, and in the *Paradiso* the poet reserved for him a place marked by a crown.

Many of the contemporary documents for the life of Henry VII. are found in the *Rerum Italicarum scriptores*, ed. L. A. Muratori (Milan, 1723-51), in *Fontes rerum Germanicarum*, ed. J. F. Böhmer (Stuttgart, 1843-68), and in *Die Geschichtsschreiber der deutschen Vorzeit*, Bde. 79 and 80 (Leipzig, 1884). See also *Acta Henrici VII. imperatoris Romanorum*, ed. G. Dönniges (1839); F. Bonaini, *Acta Henrici VII. Romanorum imperatoris* (Florence, 1877); T. Lindner, *Deutsche Geschichte unter den Habsburgern und Luxemburgern* (Stuttgart, 1888-93); J. Heidemann, "Die Königswahl Heinrichs von Luxemburg," in the *Forschungen zur deutschen Geschichte*, Bd. xi. (Göttingen, 1862-86); B. Graefe, *Die Persönlichkeit Kaiser Heinrichs VII.* (1911); and F. Schneider, *Kaiser Heinrichs VII.* (1924).

HENRY (c. 1174-1216), emperor of Romania, or Constantinople, was a younger son of Baldwin, count of Flanders and Hainaut (d. 1195). Having joined the Fourth Crusade about 1201, he distinguished himself at the siege of Constantinople in 1204 and elsewhere, and soon became prominent among the princes of the new Latin empire of Constantinople. When his brother, the emperor Baldwin I., was captured at the battle of Adrianople in April 1205, Henry was chosen regent of the empire, succeeding to the throne when the news of Baldwin's death arrived. He was crowned on Aug. 20, 1205. Henry was a wise ruler, whose reign was largely passed in successful struggles with the Bulgarians and with his rival, Theodore Lascaris I., emperor of Nicaea. Henry appears to have been brave but not cruel, and tolerant but not weak; possessing "the superior courage to oppose, in a superstitious age, the pride and avarice of the clergy." He died, poisoned, it is said, by his Greek wife, on June 11, 1216. See Gibbon's *Decline and Fall of the Roman Empire*, vol. vi. (ed. J. B. Bury, 1898).

HENRY I. (1207?-1217), king of Castile, son of Alphonso VIII. of Castile and Eleanor of Aquitaine, daughter of Henry II. of England, born c. 1207. He was killed by the fall of a tile.

HENRY II. OF TRASTAMARA (1333-1379), king (1369) of Castile, eldest son of Alphonso XI. and his mistress, Leonora de Guzman. His father endowed him with great lordships in northern Spain, and made him count of Trastamara. After the accession of Alphonso's legitimate son, Peter the Cruel, Henry fled (1356) to France. In 1366 he persuaded the mercenary soldiers paid off by the kings of England and France to join him on an expedition to drive out Peter. The expedition was successful, but the Black Prince intervened on behalf of Peter and defeated Henry at Nájera (April 3, 1367). Henry fled to Aragon, returned with French soldiers of fortune under du Guesclin, besieged Peter in Montiel (La Mancha), tempted him out and killed him on March 23, 1369. Through his ten years' reign Henry remained a strong ally of the French king in his wars with the English, who supported the claims of Peter's natural daughters. To support his own, he made vast grants and concessions to nobles and cities, hence his title *El de las Mercedes*—he of the largesse.

HENRY III. (1379-1406), king (1390) of Castile, "El Doliente" (the Sufferer), was the son of John I., of Castile and Leon, and Beatrice, daughter of Ferdinand of Portugal. Though delicate and a minor, he succeeded, by the generous support of the cities, in regaining (1393) his crown lands from the nobles. In 1394 he summoned the Cortes at Madrid, and established a practically despotic royal authority, based on the consent of the commons. His marriage with Catherine, grand-daughter of Peter the Cruel united the rival claims of the descendants of Peter and of Henry of Trastamara. He died on Dec. 25, 1406.

HENRY IV. (1425-1474), king of Castile, "the Impotent," was the son of John II. of Castile and Leon and of Mary, daughter of Ferdinand I. of Aragon and Sicily. Born at Valladolid on

Jan. 6, 1425, he was weak and vacillating in character, and his reign was marked by incidents of the most ignominious kind. He divorced (1453) his wife Blanche of Navarre on the ground of mutual impotence, married Joan of Portugal in 1468, repudiated the daughter that she bore him, then claimed her for his own. Deposed in favour of his brother Alphonso in 1468, he was restored at the latter's death in the same year. He died at Madrid on Dec. 12, 1474.

HENRY I. (1068-1135), king of England, nicknamed Beauclerk, the fourth and youngest son of William I. by his queen Matilda of Flanders, was born in 1068 on English soil. Of his life before 1086, when he was solemnly knighted by his father at Westminster, we know little. He was his mother's favourite, and she bequeathed to him her English estates, which, however, he was not permitted to hold in his father's lifetime. Henry was given an excellent education, of which in later life he was proud. His attainments included Latin, which he could both read and write; he knew something of the English laws and language, and it may have been from an interest in natural history that he collected, during his reign, the Woodstock menagerie which was the admiration of his subjects. But from 1087 his life was one of action and vicissitudes which left him little leisure. Receiving, under the Conqueror's last dispositions, a legacy of 5,000 pounds of silver, but no land, he traded upon the pecuniary needs of Duke Robert of Normandy, from whom he purchased, for the small sum of £3,000, the district of the Cotentin. He negotiated with Rufus to obtain the possession of their mother's inheritance, but only incurred thereby the suspicions of the duke, who threw him into prison. In 1090 the prince vindicated his loyalty by suppressing, on Robert's behalf, a revolt of the citizens of Rouen which Rufus had fomented. But when his elder brothers were reconciled in the next year they combined to evict Henry from the Cotentin. He dissembled his resentment for a time, and lived for nearly two years in the French Vexin in great poverty. He then accepted from the citizens of Domfront an invitation to defend them against Robert of Bellême; and subsequently, coming to an agreement with Rufus, assisted the king in making war on their elder brother Robert. When Robert's departure for the First Crusade left Normandy in the hands of Rufus (1096) Henry took service under the latter, and he was in the royal hunting train on the day of Rufus's death (Aug. 2, 1100).

Had Robert been in Normandy the claim of Henry to the English crown might have been effectually opposed. But Robert only returned to the duchy a month after Henry's coronation. In the meantime the new king, by issuing his famous charter, by recalling Anselm, and by choosing the Anglo-Scottish princess Edith-Matilda, daughter of Malcolm III., king of the Scots, as his future queen, had cemented that alliance with the church and with the native English which was the foundation of his greatness. Anselm preached in his favour, English levies marched under the royal banner both to repel Robert's invasion (1101) and to crush the revolt of the Montgomeries headed by Robert of Bellême (1102). The alliance of crown and church was subsequently imperilled by the question of Investitures (1103-1106). Henry was sharply criticized for his ingratitude to Anselm (*q.v.*), in spite of the marked respect which he showed to the archbishop. At this juncture a sentence of excommunication would have been a dangerous blow to Henry's power in England. But the king's diplomatic skill enabled him to satisfy the church without surrendering any rights of consequence (1106); and he skilfully threw the blame of his previous conduct upon his counsellor, Robert of Meulan. Although the *Peterborough Chronicle* accuses Henry of oppression in his early years, the nation soon learned to regard him with respect. William of Malmesbury, about 1125, already treats Tinchebrai (1106) as an English victory and the revenge for Hastings. Henry was disliked but feared by the baronage, towards whom he showed gross bad faith in his disregard of his coronation promises. In 1110 he banished the more conspicuous malcontents, and from that date was safe against the plots of his English feudatories.

With Normandy he had more trouble, and the military skill which he had displayed at Tinchebrai was more than once put to

the test against Norman rebels. His Norman, like his English administration, was popular with the non-feudal classes, but doubtless oppressive towards the barons. The latter had abandoned the cause of Duke Robert, who remained a prisoner in England till his death (1134); but they embraced that of Robert's son William the Clito, whom Henry in a fit of generosity had allowed to go free after Tinchebrai. The Norman conspiracies of 1112, 1118 and 1123-24 were all formed in the Clito's interest. Both France and Anjou supported this pretender's cause from time to time; he was always a thorn in Henry's side till his untimely death at Alost (1128), but more especially after the catastrophe of the White Ship (1120) deprived the king of his only lawful son. But Henry emerged from these complications with enhanced prestige. His campaigns had been uneventful, his chief victory (Brémule, 1119) was little more than a skirmish. But he had held his own as a general, and as a diplomatist he had shown surpassing skill. The chief triumphs of his foreign policy were the marriage of his daughter Matilda to the emperor Henry V. (1114) which saved Normandy in 1124; the detachment of the pope, Calixtus II., from the side of France and the Clito (1119), and the Angevin marriages which he arranged for his son William Aetheling (1119) and for the widowed empress Matilda (1129) after her brother's death. This latter match, though unpopular in England and Normandy, was a fatal blow to the designs of Louis VI., and prepared the way for the expansion of English power beyond the Loire. After 1124 the disaffection of Normandy was crushed. The severity with which Henry treated the last rebels was regarded as a blot upon his fame; but the only case of merely vindictive punishment was that of the poet Luke de la Barre, who was sentenced to lose his eyes for a lampoon upon the king, and only escaped the sentence by committing suicide.

Henry's English government was severe and grasping; but he "kept good peace" and honourably distinguished himself among contemporary statesmen in an age when administrative reform was in the air. He spent more time in Normandy than in England. But he showed admirable judgment in his choice of subordinates; Robert of Meulan, who died in 1118, and Roger of Salisbury, who survived his master, were statesmen of no common order; and Henry was free from the mania of attending in person to every detail, which was the besetting sin of mediæval sovereigns. As a legislator Henry was conservative. He issued few ordinances; the unofficial compilation known as the *Leges Henrici* shows that, like the Conqueror, he made it his ideal to maintain the "law of Edward." His itinerant justices were not altogether a novelty in England or Normandy. It is characteristic of the man that the exchequer should be the chief institution created in his reign. The eulogies of the last *Peterborough Chronicle* on his government were written after the anarchy of Stephen's reign had invested his predecessor's "good peace" with the glamour of a golden age. Henry was respected and not tyrannous. He showed a lofty indifference to criticism such as that of Eadmer in the *Historia novorum*, which was published early in the reign. He showed, on some occasions, great deference to the opinions of the magnates. But dark stories, some certainly unfounded, were told of his prison-houses. Men thought him more cruel and more despotic than he actually was.

Henry was twice married. After the death of his first wife, Matilda (1080-1118), he took to wife Adelaide, daughter of Godfrey, count of Louvain (1121), in the hope of male issue. But the marriage proved childless, and the empress Matilda was designated as her father's successor, the English baronage being compelled to do her homage both in 1126, and again, after the Angevin marriage, in 1131. He had many illegitimate sons and daughters by various mistresses. Of these bastards the most important is Robert, earl of Gloucester, upon whom fell the main burden of defending Matilda's title against Stephen.

Henry died near Gisors on Dec. 1, 1135, in the 36th year of his reign, and was buried in the abbey of Reading which he himself had founded.

HENRY II. (1133-1189), king of England, son of Geoffrey Plantagenet, count of Anjou, by Matilda, daughter of Henry I., was born at Le Mans on March 25, 1133. He was brought to England during his mother's conflict with Stephen (1142), and was placed under the charge of a tutor at Bristol. He returned to Normandy in 1146. He next appeared on English soil in 1149¹ when he came to court the help of Scotland and the English baronage against King Stephen. The second visit was of short duration. In 1150 he was invested with Normandy by his father, whose death in the next year made him also count of Anjou. In 1152 by a marriage with Eleanor of Aquitaine, the divorced wife of the French king Louis VII., he acquired Poitou, Guienne and Gascony; but in doing so incurred the ill-will of his suzerain from which he suffered not a little in the future. Lastly in 1153 he was able, through the aid of the Church and his mother's partisans, to extort from Stephen the recognition of his claim to the English succession; and this claim was asserted without opposition immediately after Stephen's death (Oct. 25, 1154).

The first years of the reign were largely spent in restoring the public peace and recovering for the crown the lands and prerogatives which Stephen had bartered away. Amongst the older partisans of the Angevin house the most influential were Archbishop Theobald, whose good will guaranteed to Henry the support of the Church, and Nigel, bishop of Ely, who presided at the exchequer. But Thomas Becket, archdeacon of Canterbury, a younger statesman whom Theobald had discovered and promoted, soon became all-powerful. Becket lent himself entirely to his master's ambitions, which at this time centred round schemes of territorial aggrandizement. In 1155 Henry asked and obtained from Adrian IV. a licence to invade Ireland, which the king contemplated bestowing upon his brother, William of Anjou. This plan was dropped; but Malcolm of Scotland was forced to restore the northern counties which had been ceded to David; North Wales was invaded in 1157; and in 1159 Henry made an attempt, which was foiled by the intervention of Louis VII., to assert his wife's claims upon Toulouse. After vainly invoking the aid of the emperor Frederick I., the young king came to terms with Louis (1160), whose daughter was betrothed to Henry's namesake and heir. The peace proved unstable, and there was desultory skirmishing in 1161. The following year was chiefly spent in reforming the government of the continental provinces. In 1163 Henry returned to England, and almost immediately embarked on that quarrel with the Church which is the keynote to the middle period of the reign.

Henry had good cause to complain of the ecclesiastical courts, and had only awaited a convenient season to correct abuses which were admitted by all reasonable men. But he allowed the question to be complicated by personal issues. He was bitterly disappointed that Becket, on whom he bestowed the primacy, left vacant by the death of Theobald (1162), at once became the champion of clerical privilege; he and the archbishop were no longer on speaking terms when the Constitutions of Clarendon came up for debate. The king's demands were not intrinsically irreconcilable with the canon law, and the papacy

would probably have allowed them to take effect *sub silentio*, if Becket (*q.v.*) had not been goaded to extremity by persecution in the forms of law. After Becket's flight (1164), the king put himself still further in the wrong by impounding the revenues of Canterbury and banishing at one stroke a number of the archbishop's friends and connections. He showed, however, considerable dexterity in playing off the emperor against Alexander III. and Louis VII., and contrived for five years, partly by these means, partly by insincere negotiations with Becket, to stave off a papal interdict upon his dominions. When, in July 1170, he was forced by Alexander's threats to make terms with Becket, the king contrived that not a word should be said of the Constitutions. He undoubtedly hoped that in this matter he would have his way when Becket should be more in England and within his grasp. For the murder of Becket (Dec. 29, 1170) the king cannot be held responsible, though the deed was suggested by his impatient words. It was a misfortune to the royal cause; and Henry was compelled to purchase the papal absolution by a complete surrender on the question of criminous clerks (1172). When he heard of the murder he was panic-stricken; and his expedition to Ireland (1171), although so momentous for the future, was originally a mere pretext for placing himself beyond the reach of Alexander's censures.

Becket's fate, though it supplied an excuse, was certainly not the real cause of the troubles with his sons which disturbed the king's later years (1173-1189). But Henry's misfortunes were largely of his own making. Queen Eleanor, whom he alienated by his faithlessness, stirred up her sons to rebellion; and they had grievances enough to be easily persuaded. Henry was an affectionate but a suspicious and close-handed father. The titles which he bestowed on them carried little power, and served chiefly to denote the shares of the paternal inheritance which were to be theirs after his death. The excessive favour which he showed to John, his youngest-born, was another cause of heart-burning; and Louis, the old enemy, did his utmost to foment all discords. It must, however, be remembered in Henry's favour, that the supporters of the princes, both in England and in the foreign provinces, were animated by resentment against the soundest features of the king's administration; and that, in the rebellion of 1173, he received from the English commons such hearty support that any further attempt to raise a rebellion in England was considered hopeless. Henry, like his grandfather, gained in popularity with every year of his reign. In 1183 the death of Prince Henry, the heir-apparent, while engaged in a war against his brother Richard and their father, secured a short interval of peace. But in 1184 Geoffrey of Brittany and John combined with their father's leave to make war upon Richard, now the heir-apparent. After Geoffrey's death (1186) the feud between John and Richard drove the latter into an alliance with Philip Augustus of France. The ill-success of the old king in this war aggravated the disease from which he was suffering; and his heart was broken by the discovery that John, for whose sake he had alienated Richard, was in secret league with the victorious allies. Henry died at Chinon on July 6, 1189, and was buried at Fontevraud. By Eleanor of Aquitaine the king had five sons and three daughters. His eldest son, William, died young; his other sons, Henry, Richard, Geoffrey and John, are all mentioned above. His daughters were: Matilda (1156-1189), who became the wife of Henry the Lion, duke of Saxony; Eleanor (1162-1214), who married Alphonso III., king of Castile; and Joanna, who, after the death of William of Sicily in 1189, became the wife of Raymond VI., count of Toulouse, having previously accompanied her brother, Richard, to Palestine. He had also three illegitimate sons: Geoffrey, archbishop of York; Morgan; and William Longsword, earl of Salisbury.

Henry's power impressed the imagination of his contemporaries, who credited him with aiming at the conquest of France and the acquisition of the imperial title. But his ambitions of conquest were comparatively moderate in his later years. He attempted to secure Maurienne and Savoy for John by a marriage-alliance, for which a treaty was signed in 1173. But the project failed through the death of the intended bride; nor did

¹For a supposed visit in 1147, see J. H. Round in *English Historical Review*, v. 747.

the marriage of his third daughter, the princess Joanna (1165-1199), with William II., king of Sicily (1177) lead to English intervention in Italian politics. Henry once declined an offer of the empire, made by the opponents of Frederick Barbarossa; and he steadily supported the young Philip Augustus against the intrigues of French feudatories. The conquest of Ireland was carried out independently of his assistance, and perhaps against his wishes. He asserted his suzerainty over Scotland by the treaty of Falaise (1175), but not so stringently as to provoke Scottish hostility. This moderation was partly due to the embarrassments produced by the ecclesiastical question and the rebellions of the princes. But Henry, despite a violent and capricious temper, had a strong taste for the work of a legislator and administrator. He devoted infinite pains and thought to the reform of government both in England and Normandy. The legislation of his reign was probably in great part of his own contriving. His supervision of the law courts was close and jealous; he transacted a great amount of judicial business in his own person, even after he had formed a high court of justice which might sit without his personal presence. To these activities he devoted his scanty intervals of leisure. His government was stern; he over-rode the privileges of the baronage without regard to precedent; he persisted in keeping large districts under the arbitrary and vexatious jurisdiction of the forest-courts. But it is the general opinion of historians that he had a high sense of his responsibilities and a strong love of justice; despite the looseness of his personal morals, he commanded the affection and respect of Gilbert Foliot and Hugh of Lincoln, the most upright of the English bishops.

ORIGINAL AUTHORITIES.—Henry's laws are printed in W. Stubbs's *Select Charters* (Oxford, 1895). The chief chroniclers of his reign are William of Newburgh, Ralph de Diceto, the so-called Benedict of Peterborough, Roger of Hoveden, Robert de Torigni (or de Monte), Jordan Fantosme, Giraldus Cambrensis, Gervase of Canterbury; all printed in the *Rolls Series*. The biographies and letters contained in the 7 vols. of *Materials for the History of Thomas Becket* (ed. J. C. Robertson, *Rolls Series*, 1875-85) are valuable for the early and middle part of the reign. For Irish affairs the *Song of Dermot* (ed. Orpen, Oxford, 1892), for the rebellions of the princes the metrical *Histoire de Guillaume le Maréchal* (ed. Paul Meyer, 3 vols., Paris, 1891, etc.) are of importance. Henry's legal and administrative reforms are illustrated by the *Tractatus de legibus* attributed to Ranulph Glanville, his chief justiciar (ed. G. Phillips, Berlin, 1828); by the *Dialogus de scaccario* of Richard fitz Nigel (Oxford, 1902); the *Pipe Rolls*, printed by J. Hunter for the Record Commission (1844) and by the Pipe-Roll Society (1884, etc.) supply valuable details. The works of John of Salisbury (ed. Giles, 1848), Peter of Blois (ed. Migne), Walter Map (Camden Society, 1841, 1850) and the letters of Gilbert Foliot (ed. J. A. Giles, 1845) are useful for the social and Church history of the reign.

MODERN AUTHORITIES.—R. W. Eyton, *Itinerary of Henry II.* (1878); W. Stubbs, *Constitutional History*, vol. i. (1893), *Lectures on Mediaeval and Modern History* (1886) and *Early Plantagenets* (1876); the same author's introduction to the *Rolls* editions of "Benedict," Gervase, Diceto, Hoveden; Mrs. J. R. Green, *Henry II.* (1888); Miss K. Norgate, *England under the Angevin Kings* (2 vols., 1887); Sir J. H. Ramsay's *The Angevin Empire* (1893); H. W. C. Davis's *England under the Normans and Angevins* (1905); Sir F. Pollock and F. W. Maitland, *History of English Law* (2 vols., 1898); and F. Hardegen, *Imperialpolitik König Heinrichs II. von England* (Heidelberg, 1905). (H. W. C. D.)

HENRY III. (1207-1272), king of England, was the eldest son of King John by Isabella of Angoulême. Born on Oct. 1, 1207, the prince was but nine years old at the time of his father's death. The greater part of eastern England being in the hands of the French pretender, Louis, afterwards Louis VIII., and the rebel barons, Henry was crowned by his supporters at Gloucester, the western capital. John had committed his son to the protection of the Holy See; and a share in the government was accordingly allowed to the papal legates, Gualo and Pandulf, both during the civil war and for some time afterwards. But the title of regent was given by the loyal barons to William Marshal, the aged earl of Pembroke; and Peter des Roches, the Poitevin bishop of Winchester, received the charge of the king's person. The cause of the young Henry was fully vindicated by the end of 1217. Defeated both by land and sea, the French prince renounced his pretensions and evacuated England, leaving the regency to deal with the more difficult questions raised by the lawless insolence of the

royal partisans. Henry remained a passive spectator of the measures by which William Marshal (d. 1219) and his successor, the justiciar Hubert de Burgh, asserted the royal prerogative against native barons and foreign mercenaries. In 1223 Honorius III. declared the king of age, but this was a mere formality, intended to justify the resumption of the royal castles and demesnes which had passed into private hands during the civil war.

The personal rule of Henry III. began in 1227, when he was again proclaimed of age. Even then he remained for some time under the influence of Hubert de Burgh, whose chief rival, Peter des Roches, found it expedient to quit the kingdom for four years. But Henry was ambitious to recover the continental possessions which his father had lost. Against the wishes of the justiciar he planned and carried out an expedition to the west of France (1230) and, when it failed, laid the blame upon his minister. Other differences arose soon afterwards. Hubert was accused, with some reason, of enriching himself at the expense of the crown, and of encouraging popular riots against the alien clerks for whom the papacy was providing at the expense of the English Church. He was disgraced in 1232; and power passed for a time into the hands of Peter des Roches, who filled the administration with Poitevins. So began the period of misrule by which Henry III. is chiefly remembered. The Poitevins fell in 1234; they were removed at the demand of the barons and the primate Edmund Rich, who held them responsible for the tragic fate of the rebellious Richard Marshal. But the king replaced them with a new clique of servile and rapacious favourites. Disregarding the wishes of the Great Council, and excluding all the more important of the barons and bishops from office, he acted as his own chief minister and never condescended to justify his policy except when he stood in need of subsidies. When these were refused, he extorted aids from the towns, the Jews or the clergy, the three most defenceless bodies in the kingdom. Always in pecuniary straits through his extravagance, he pursued a foreign policy which would have been expensive under the most careful management. He hoped not only to regain the French possessions but to establish members of his own family as sovereigns in Italy and the Empire. These plans were artfully fostered by the Savoyard kinsmen of Eleanor, daughter of Raymond Berenger, count of Provence, whom he married at Canterbury on Jan. 14, 1236, and by his half-brothers, the sons of Queen Isabella and Hugo, count of la Marche. These favourites, not content with pushing their fortunes in the English court, encouraged the king in the wildest designs. In 1242 he led an expedition to Gascony which terminated disastrously with the defeat of Taillebourg; and hostilities with France were intermittently continued for 17 years. The Savoyards encouraged his natural tendency to support the Papacy against the Empire; early in the period of misrule he entered into a close alliance with Rome, which resulted in heavy taxation of the clergy and gave great umbrage to the barons. A cardinal-legate was sent to England at Henry's request, and during four years (1237-41) administered the English Church in a manner equally profitable to the king and the pope. After the recall of the legate Otho the alliance was less open and less cordial. Still the pope continued to share the spoils of the English clergy with the king, and the king to enforce the demands of Roman tax-collectors.

Circumstances favoured Henry's schemes. Archbishop Edmund Rich was timid and inexperienced; his successor, Boniface of Savoy, was a kinsman of the queen; Grosseteste, the most eminent of the bishops, died in 1253, when he was on the point of becoming a popular hero. Among the lay barons, the first place naturally belonged to Richard of Cornwall who, as the king's brother, was unwilling to take any steps which might impair the royal prerogative; while Simon de Montfort, earl of Leicester, the ablest man of his order, was regarded with suspicion as a foreigner, and linked to Henry's cause by his marriage with the princess Eleanor. Although the Great Council repeatedly protested against the king's misrule and extravagance, their remonstrances came to nothing for want of leaders and a clear-cut policy. But between 1248 and 1252 Henry alienated Montfort from his cause by taking the side of the Gascons, whom the earl had provoked to rebellion through his rigorous administration of their

duchy. A little later, when Montfort was committed to opposition, Henry foolishly accepted from Innocent IV. the crown of Sicily for his second son Edmund Crouchback (1255). Sicily was to be conquered from the Hohenstaufen at the expense of England; and Henry pledged his credit to the papacy for enormous subsidies, although years of comparative inactivity had already overwhelmed him with debts. On the publication of the ill-considered bargain the baronage at length took vigorous action. They forced upon the king the Provisions of Oxford (1258), which placed the government in the hands of a feudal oligarchy; they reduced expenditure, expelled the alien favourites from the kingdom, and insisted upon a final renunciation of the French claims. The king submitted for the moment, but at the first opportunity endeavoured to cancel his concessions. He obtained a papal absolution from his promises; and he tricked the opposition into accepting the arbitration of the French king, Louis IX., whose verdict was a foregone conclusion. But Henry was incapable of protecting with the strong hand the rights which he had recovered by his double-dealing. Ignominiously defeated by Montfort at Lewes (1264) he fell into the position of a cipher, equally despised by his opponents and supporters. He acquiesced in the earl's dictatorship; left to his eldest son, Edward, the difficult task of reorganizing the royal party; marched with the Montfortians to Evesham; and narrowly escaped sharing the fate of his gaoler. After Evesham (1265) he is hardly mentioned by the chroniclers. The compromise with the surviving rebels was arranged by his son in concert with Richard of Cornwall and the legate Ottobuono; the statute of Marlborough (1267), which purchased a lasting peace by judicious concessions, was similarly arranged between Edward and the earl of Gloucester. Edward was king in all but name for some years before the death of his father, by whom he was alternately suspected and adored.

Henry had in him some of the elements of a fine character. His mind was cultivated; he was a discriminating patron of literature, and Westminster Abbey is an abiding memorial of his artistic taste. His personal morality was irreproachable, except that he inherited the Plantagenet taste for crooked courses and dissimulation in political affairs; even in this respect the king's reputation has suffered unduly at the hands of Matthew Paris, whose literary skill is only equalled by his malice. The ambitions which Henry cherished, if extravagant, were never sordid; his patriotism, though seldom attested by practical measures, was thoroughly sincere. Some of his worst actions as a politician were due to a sincere, though exaggerated, gratitude for the support which the Papacy had given him during his minority. But he had neither the training nor the temper of a statesman. His dreams of autocracy at home and far-reaching dominion abroad were anachronisms in a century of constitutional ideas and national differentiation. Above all he earned the contempt of Englishmen and foreigners alike by the instability of his purpose. Matthew Paris said that he had a heart of wax; Dante relegated him to the limbo of ineffectual souls; and later generations have endorsed these scathing judgments.

Henry died at Westminster on Nov. 16, 1272; his widow, Eleanor, took the veil in 1276 and died at Amesbury on June 25, 1291. Their children were: the future king Edward I.; Edmund, earl of Lancaster; Margaret (1240-75), wife of Alexander III., of Scotland; Beatrice; and Katherine.

HENRY IV. (1367-1413), king of England, son of John of Gaunt, by Blanche, daughter of Henry, duke of Lancaster, was born on April 3, 1367, at Bolingbroke in Lincolnshire. As early as 1377 he is styled earl of Derby, and in 1380 he married Mary de Bohun (d. 1394) one of the co-heiresses of the last earl of Hereford. In 1387 he supported his uncle Thomas, duke of Gloucester, in his armed opposition to Richard II. and his favourites. Afterwards, probably through his father's influence, he changed sides. He was already distinguished for his knightly prowess, and for some years devoted himself to adventure. He thought of going on the crusade to Barbary; but instead, in July 1390, went to serve with the Teutonic knights in Lithuania. He came home in the following spring, but next year went again to Prussia, whence he journeyed by way of Venice to Cyprus and Jerusalem. After his return to England he sided with his father and the king against Gloucester, and in 1397 was made duke of Hereford. In Jan. 1398 he quarrelled with the duke of Norfolk, who charged him with treason. The dispute was to have been decided in the lists at Coventry in September; but at the last moment Richard intervened and banished them both.

When John of Gaunt died in Feb. 1399 Richard, contrary to his promise, confiscated the estates of Lancaster. Henry then felt himself free, and made friends with the exiled Arundels. Early in July, whilst Richard was absent in Ireland, he landed at Ravenspur in Yorkshire. He was at once joined by the Percies; and Richard, abandoned by his friends, surrendered at Flint on Aug. 19. On Richard's abdication Henry claimed the crown by right of blood from King Henry III., and through his right to recover the realm which was in point to be undone for default of governance and good law. Parliament formally accepted him, and thus Henry became king, "not so much by title of blood as by popular election" (Capgrave). The new dynasty had consequently a constitutional basis. But though the revolution of 1399 was popular in form, its success was due to an oligarchical faction. From the start Henry was embarrassed by the power and pretensions of the Percies. Nor was his hereditary title so good as that of the Mortimers. To domestic troubles was added the complication of disputes with Scotland and France. The first danger came from the friends of Richard, who plotted prematurely, and were crushed in Jan. 1400. During the summer of 1400 Henry made a not over-successful expedition to Scotland. The French court would not accept his overtures, but in the summer of 1401 a truce was patched up by the restoration of Richard's child-queen, Isabella of Valois. Meantime in 1400 and again in each of the two following autumns Henry tried in vain to subdue the revolt of Owen Glendower (*q.v.*). The success of the Percies over the Scots at Homildon Hill (Sept. 1402) was no advantage. Henry Percy (Hotspur) and his father, the earl of Northumberland, thought their services ill-requited, and finally made common cause with the partisans of Mortimer and the Welsh. The plot was frustrated by Hotspur's defeat at Shrewsbury (July 21, 1403); and Northumberland for the time submitted. Henry had, however, no one on whom he could rely outside his own family, except Archbishop Arundel. The Welsh were unsubdued; the French were plundering the southern coast; Northumberland was fomenting trouble in the north. In 1405 a plot to carry off the young Mortimers was defeated; but Mowbray, the earl marshal, who had been privy to it, raised a rebellion in the north supported by Archbishop Scrope of York. Mowbray and Scrope were taken and beheaded; Northumberland escaped into Scotland. For the execution of the archbishop Henry was personally responsible, and he could never free himself from its odium. Popular belief regarded his subsequent illness as a judgment for his impiety. Apart from ill-health and unpopularity Henry had succeeded—relations with Scotland were secured by the capture of James, the heir to the crown; Northumberland was at last crushed at Bramham Moor (Feb. 1408); and a little later the Welsh revolt was mastered.

Henry, stricken with sore disease, was unable to reap the advantage. His necessities had all along enabled the Commons to extort concessions in parliament, until in 1406 he was forced to nominate a council and govern by its advice. However, with Archbishop Arundel as his chancellor, Henry still controlled the government. But in Jan. 1410 Arundel had to give way to the king's half-brother, Thomas Beaufort. Beaufort and his brother Henry, bishop of Winchester, were opposed to Arundel and supported by the prince of Wales. For two years the real government rested with the prince and the council. Under the prince's influence the English intervened in France in 1411 on the side of Burgundy. In this, and in some matters of home politics, the king disagreed with his ministers. There is good reason to suppose that the Beauforts had gone so far as to contemplate a forced abdication on the score of the king's ill-health. However, in Nov. 1411 Henry showed that he was still capable of vigorous action by discharging the prince and his supporters. Arundel again became chancellor, and the king's second son, Thomas, took his brother's place. The change was further marked by the sending of an expedition to France in support of Orleans. But Henry's health was failing steadily. On March 20, 1413, whilst praying in Westminster Abbey he was seized with a fainting fit, and died that same evening in the Jerusalem Chamber. He was buried at Canterbury.

By Mary de Bohun Henry had four sons: his successor Henry V., Thomas, duke of Clarence, John, duke of Bedford, and Humphrey, duke of Gloucester; and two daughters, Blanche, who married Louis III., elector palatine of the Rhine, and Philippa, who married Eric XIII., king of Sweden. Henry's second wife was Joan, or Joanna (c. 1370-1437), daughter of Charles the Bad, king of Navarre, and widow of John IV. or V., duke of Brittany, who survived until July 1437. By her he had no children.

BIBLIOGRAPHY.—The chief contemporary authorities are the *Annales Henrici Quarti* and T. Walsingham's *Historia Anglicana* (Rolls Series), Adam of Usk's *Chronicle* and the various *Chronicles of London*. The life by John Capgrave (*De illustribus Henricis*) is of little value. Some personal matter is contained in *Wardrobe Accounts of Henry, Earl of Derby* (Camden Soc.). For documents consult T. Rymer's *Foedera*; Sir N. H. Nicolas, *Proceedings and Ordinances of the Privy Council*; Sir H. Ellis, *Original Letters illustrative of English History* (1825-46); *Rolls of Parliament*; *Royal and Historical Letters, Henry IV.* (Rolls Series) and the *Calendars of Patent Rolls*. Of modern authorities the foremost is J. H. Wylie's minute and learned *Hist. of England under Henry IV.* (4 vols., 1884-1898). See also W. Stubbs, *Constitutional History*; Sir J. Ramsay, *Lancaster and York* (2 vols., Oxford, 1892), and C. W. C. Oman, *The Political History of England*, vol. iv. (C. L. K.)

HENRY V. (1387-1422), king of England, son of Henry IV. by Mary de Bohun, was born at Monmouth, in Aug. 1387. On his father's exile in 1398 Richard II. took the boy into his own charge, and treated him kindly. Next year the Lancastrian revolution forced Henry into precocious prominence as heir to the throne. From Oct. 1400 the administration of Wales was conducted in his name; less than three years later he was in actual command of the English forces and fought against the Percies at Shrewsbury. The Welsh revolt absorbed his energies till 1408. Then through the king's ill-health he began to take a wider share in politics. (See HENRY IV.) In Nov. 1411 the king discharged the prince from the council. The quarrel of father and son was political only. It may be to that political enmity that the tradition of Henry's riotous youth, immortalized by Shakespeare, is partly due. To that tradition Henry's strenuous life in war and politics is a sufficient general contradiction. The most famous incident, his quarrel with the chief-justice, has no contemporary authority and was first related by Sir Thomas Elyot in 1531. The story of Falstaff originated partly in Henry's early friendship for Oldcastle (q.v.). That friendship, and the prince's political opposition to Archbishop Arundel, perhaps encouraged Lollard hopes. If so, their disappointment may account for the statements of ecclesiastical writers, like Walsingham, that Henry on becoming king was changed suddenly into a new man.

Henry succeeded his father on March 20, 1413. He had to deal with three main problems—the restoration of domestic peace, the healing of schism in the Church and the recovery of English

prestige in Europe. Henry grasped them all together, and gradually built upon them a yet wider policy. From the first he made it clear that past differences were to be forgotten. Richard II. was honourably re-interred; the young Mortimer was taken into favour; the heirs of those who had suffered in the last reign were restored gradually to their titles and estates. With Oldcastle Henry used his personal influence in vain, and the gravest domestic danger was Lollard discontent. But the king's firmness nipped the movement in the bud (Jan. 1414), and made his own position as ruler secure. Save for the abortive Scrope and Cambridge plot in favour of Mortimer in July 1415, the rest of his reign was free from serious trouble at home.

Henry could now turn his attention to foreign affairs. Old commercial disputes and the support which the French had lent to Glendower gave a pretext for war with France. The campaign of 1415, with its brilliant conclusion at Agincourt (Oct. 25), was only the first step. Two years of patient preparation followed. The command of the sea was secured by driving the Genoese allies of the French out of the Channel. A successful diplomacy detached the emperor Sigismund from France, and by the Treaty of Canterbury paved the way to end the schism in the Church. In 1417 the war was renewed on a larger scale. Lower Normandy was quickly conquered, Rouen cut off from Paris and besieged. The French were paralysed by the disputes of Burgundians and Armagnacs. Henry skilfully played them off one against the other, without relaxing his warlike energy. In Jan. 1419 Rouen fell. By August the English were outside the walls of Paris. The intrigues of the French parties culminated in the assassination of John of Burgundy by the dauphin's partisans at Montereau (Sept. 10, 1419). Philip, the new duke, and the French court threw themselves into Henry's arms. After six months' negotiation Henry was, by the Treaty of Troyes, recognized as heir and regent of France, and on June 2, 1420, married Catherine, the king's daughter. He was now at the height of his power. His eventual success in France seemed certain. He shared with Sigismund the credit of having ended the Great Schism by obtaining the election of Pope Martin V. All the states of western Europe were being brought within the web of his diplomacy. The headship of Christendom was in his grasp, and schemes for a new crusade began to take shape. He actually sent an envoy to collect information in the East; but his plans were cut short by death. A visit to England in 1421 was interrupted by the defeat of Clarence at Baugé. The hardships of the longer winter siege of Meaux broke down his health, and he died at Bois de Vincennes on Aug. 3, 1422.

Henry's last words were a wish that he might live to rebuild the walls of Jerusalem. They are significant. His ideal was founded consciously on the models of Arthur and Godfrey as national king and leader of Christendom. So he is the typical mediaeval hero. For that very reason his schemes were doomed to end in disaster, since the time was come for a new departure. Yet he was not reactionary. His policy was constructive: a firm central government supported by parliament; church reform on conservative lines; commercial development; and the maintenance of national prestige. His aims in some respects anticipated those of his Tudor successors, but he would have accomplished them on mediaeval lines as a constitutional ruler. His success was due to the power of his personality. He could train able lieutenants, but at his death there was no one who could take his place as leader. War, diplomacy and civil administration were all dependent on his guidance. His dazzling achievements as a general have obscured his more sober qualities as a ruler, and even the sound strategy, with which he aimed to be master of the narrow seas. If he was not the founder of the English navy he was one of the first to realize its true importance. Henry had so high a sense of his own rights that he was merciless to disloyalty. But he was scrupulous of the rights of others, and it was his eager desire to further the cause of justice that impressed his French contemporaries. He has been charged with cruelty as a religious persecutor; but in fact he had as prince opposed the harsh policy of Archbishop Arundel, and as king sanctioned a more moderate course. Lollard executions during his reign had more often a political than a religious reason. To be just with sternness was in

his eyes a duty. In his personal conduct Henry was chaste, temperate and sincerely pious. He delighted in sport and all manly exercises. He was cultured with a taste for literature, art and music. Henry lies buried in Westminster Abbey. His tomb was stripped of its splendid adornment during the Reformation. The shield, helmet and saddle, which formed part of the original funeral equipment, still hang above it.

BIBLIOGRAPHY.—Of original authorities the best on the English side is the *Gesta Henrici Quinti* (down to 1416), printed anonymously for the English Historical Society, but probably written by Thomas Elmham, one of Henry's chaplains. Two lives edited by Thomas Hearne under the names of Elmham and Titus Livius Forojuliensis come from a common source; the longer, which Hearne ascribed incorrectly to Elmham, is perhaps the original work of Livius, who was an Italian in the service of Humphrey of Gloucester, and wrote about 1440. Other authorities are the *Chronicles of Walsingham* and *Otterbourne the English Chronicle or Brut*, and the various *London Chronicles*. On the French side the most valuable are *Chronicles of Monstrelet* and *St. Rémy* (both Burgundian) and the *Chronique du religieux de St. Denys* (the official view of the French court). For documents and modern authorities see under HENRY IV. See also C. L. Kingsford, *Henry V., the Typical Mediaeval Hero* (New York, 1901); and J. H. Wylie, *The Reign of Henry V.* (2 vols. 1914-19).

HENRY VI. (1421-1471), king of England, son of Henry V. and Catherine of Valois, was born at Windsor on Dec. 6, 1421. He became king of England on Sept. 1, 1422, and a few weeks later, on the death of his grandfather Charles VI., was proclaimed king of France also. Henry V. had directed that Richard Beauchamp, earl of Warwick (*q.v.*), should be his son's preceptor. As early as 1423 the baby king was made to appear at public functions and take his place in parliament. He was knighted by his uncle, Bedford at Leicester in May 1426, and on Nov. 6, 1429, was crowned at Westminster. Early in the next year he was taken over to France, and after long delay crowned in Paris on Dec. 16, 1431. His return to London Feb. 14, 1432 was celebrated with a great pageant devised by Lydgate.

During these early years Bedford ruled France wisely and at first with success, but he could not prevent the mischief which Humphrey of Gloucester (*q.v.*) caused both at home and abroad. Even in France the English lost ground steadily after the victory of Joan of Arc before Orleans in 1429. The climax came with the death of Bedford, and defection of Philip of Burgundy in 1435. This closed the first phase of Henry's reign. There followed 15 years of vain struggle in France, and growing disorder at home. The determining factor in politics was the conduct of the war. Cardinal Beaufort, and after him Suffolk, sought by working for peace to secure at least Guienne and Normandy. Gloucester courted popularity by opposing them throughout; with him was Richard of York, who stood next in succession to the crown. Beaufort controlled the council, and it was under his guidance that the king began to take part in the government. Thus it was natural that as Henry grew to manhood he seconded heartily the unpopular and difficult peace policy. Henry was unfortunate in his advisers. The cardinal was old, his nephews John and Edmund Beaufort were incompetent, Suffolk was tactless. Suffolk, however, achieved a great success by negotiating the marriage of Henry to Margaret of Anjou (*q.v.*) in 1445. Humphrey of Gloucester and Cardinal Beaufort both died early in 1447. Suffolk was now all-powerful in the favour of the king and queen. But his home administration was unpopular, whilst the incapacity of Edmund Beaufort ended in the loss of all Normandy and Guienne. Suffolk's fall in 1450 left Richard of York the foremost man in England. Henry's reign then entered on its last phase of dynastic struggle. Cade's rebellion suggested first that popular discontent might result in a change of rulers. But York, as heir to the throne, could bide his time. The situation was altered by the mental derangement of the king, and the birth of his son in 1453. York after a struggle secured the protectorship, and for the next year ruled England. Then Henry was restored to sanity, and the queen and Edmund Beaufort, now duke of Somerset, to power. Open war followed (*see WARS OF THE ROSES*), with the defeat and death of Somerset at St. Albans on May 22, 1455. Nevertheless a hollow peace was patched up, which continued during four years with lack of all governance. In 1459 war broke out again. On July

10, 1460 Henry was taken prisoner at Northampton, and forced to acknowledge York as heir, to the exclusion of his own son. Richard of York's death at Wakefield (Dec. 29, 1460), and the queen's victory at St. Albans (Feb. 17, 1461), brought Henry his freedom and no more. Edward of York had himself proclaimed king, and by his decisive victory at Towton on March 29, put an end to Henry's reign. For over three years Henry was a fugitive in Scotland. He returned to take part in an abortive rising in 1464. A year later he was captured in the north, and brought a prisoner to the Tower. For six months in 1470-1471 he emerged to hold a shadowy kingship as Warwick's puppet. Edward's final victory at Tewkesbury was followed by Henry's death on May 21, 1471, certainly by violence, perhaps at the hands of Richard of Gloucester.

Henry was the most hapless of monarchs. He was so honest and well-meaning that he might have made a good ruler in quiet times. But he was crushed by the burden of his inheritance. He had not the genius to find a way out of the French entanglement or the skill to steer a constitutional monarchy between rival factions. Henry's very virtues added to his difficulties. He was so trusting that any one could influence him, so faithful that he would not give up a minister who had become impossible. Thus even in the middle period he had no real control of the Government. Religious observances and study were his chief occupations. For education he was really zealous. The planning of his great foundations at Eton (1440) and King's college, Cambridge (1441), was the one thing which absorbed his interest. To both he was more than a royal founder, and the credit of the whole scheme belongs to him.

Henry's only son was Edward, Prince of Wales (1453-1471), who, having shared the many journeys and varying fortunes of his mother, Margaret, was killed after the battle of Tewkesbury (May 4, 1471) by some noblemen in attendance on Edward IV.

BIBLIOGRAPHY.—There is a life of Henry by his chaplain John Blakman (printed at the end of Hearne's edition of *Otterbourne*); but it is concerned only with his piety and patience in adversity. English chronicles for the reign are scanty; the best are the *Chronicles of London* (ed. C. L. Kingsford), with the analogous *Gregory's Chronicle* (ed. J. Gairdner for Camden Soc.) and *Chronicle of London* (ed. Sir H. N. Nicolas). *The Paston Letters*, with James Gairdner's valuable introductions, are indispensable. Other useful authorities are Joseph Stevenson's *Letters and Papers illustrative of the Wars of the English in France during the Reign of Henry VI.*; and *Correspondence of T. Bekynton* (both in the "Rolls" series). For the French war the chief sources are the *Chronicles of Monstrelet*, D'Escouchy and T. Basin. For other documents and modern authorities see under HENRY IV. For Henry's foundations see Sir H. C. Maxwell-Lyte, *History of Eton College* (1899), and J. B. Mullinger, *History of the University of Cambridge* (1888). (C. L. K.)

HENRY VII. (1457-1509), king of England, grandson of John of Gaunt and Catherine Swynford, whose issue born before their marriage had been legitimated by parliament, was the first king of the Tudor (*q.v.*) dynasty. He was the son of Edmund, earl of Richmond, and Margaret Beaufort, only daughter of John, duke of Somerset, and was born in Pembroke castle on Jan. 28, 1457, two months after his father's death. During the reign of Edward IV. the child Henry was hidden in various castles until his uncle Jasper took him to Brittany. There he was joined by many Englishmen driven abroad by the cruelties of Richard III. An invasion of England was planned in 1483 in concert with the duke of Buckingham's rising; but stormy weather defeated the movement. A second expedition, two years later, aided this time by France, was successful. Henry landed at Milford Haven among his Welsh allies and defeated Richard at the battle of Bosworth (Aug. 22, 1485). He was crowned at Westminster on Oct. 30, and in fulfilment of pledges to his Yorkist supporters, married Elizabeth (1465-1503), eldest daughter and heiress of Edward IV. (Jan. 18, 1486), whose two brothers had been murdered by Richard III. Thus the Red and White Roses were united and the pretexts for civil war done away with.

Nevertheless, Henry's reign was much disturbed by a succession of Yorkist conspiracies. Of the two most notable impostors, the first, Lambert Simnel (*q.v.*) personated the earl of Warwick, son of the duke of Clarence, but the rebellion in his favour was put down at the battle of Stoke, near Newark (June 16, 1487).

This movement had been greatly assisted by the Irish and by Margaret, duchess dowager of Burgundy, sister of Edward IV. The second pretender, Perkin Warbeck (*q.v.*), who impersonated (1492) Richard duke of York, one of the princes murdered in the Tower, was also much indebted to foreign support. Anxious as Henry was to avoid foreign wars, he was committed to war with France, partly by his desire of an alliance with Spain, and partly by desire to prevent the incorporation of Brittany with France. Moreover, the French king gave assistance to Perkin Warbeck. Henry gave Brittany defensive aid; but after the duchess Anne had married Charles VIII. of France, he felt bound to fulfil his obligations to Ferdinand and Isabella of Spain, and also to the German king Maximilian, by an invasion of France in 1492. After besieging Boulogne for some little time, he made peace with France at Etaples (Nov. 3, 1492).

Meanwhile Margaret of Burgundy received Perkin Warbeck as her nephew, and Maximilian, now estranged from Henry, recognized him (1494) as king of England. Perkin Warbeck attempted to land at Deal, but sailed to Ireland and then to Scotland, where James IV. received him (Nov. 1495), married him to an earl's daughter and made a futile invasion (1496) of England with him. But in 1497 he thought best to dismiss him, and Perkin, after an unsuccessful visit to Ireland, landed with a small body of men in Cornwall, where shortly before an insurrection on account of the taxation imposed for repelling the Scottish invasion, had been put down. Perkin, after a futile siege of Exeter and an advance to Taunton, took sanctuary at Beaulieu in Hampshire, and surrendered (Sept. 1497). Imprisoned near the earl of Warwick, in the Tower, he inveigled that simple-minded youth into a project of escape. For this, both were executed (1499) and during the rest of Henry's reign no further insurrections occurred.

The king was now seeking alliances for his children. While the eldest, Arthur, was still an infant, a marriage had been proposed for him with Catherine, daughter of Ferdinand of Aragon. Catherine was now brought to England and they were married on Nov. 14, 1501. On Arthur's death in the following April, Catherine was betrothed to the king's second son, Henry. Meanwhile Henry's eldest daughter Margaret was married (1503) to James IV. of Scotland—a match intended to confirm the treaty of peace signed in July 1499 and to make possible the ultimate union of England and Scotland, which actually resulted from it. Henry's queen died on Feb. 11, 1503, and during the remainder of his reign he made fruitless proposals for a second marriage—proposals in which political objects were the chief consideration.

In his latter years the king became unpopular from the extortions practised by his two instruments, Empson and Dudley, under the authority of antiquated statutes. From the beginning of his reign he had accumulated money, mainly for his own security against intrigues and conspiracies, and avarice had grown upon him. When he died in April 1509 he was undoubtedly the richest prince in Christendom. Before his death, however, he had finished the hospital of the Savoy and made provision for the magnificent chapel at Westminster which bears his name.

Henry not only terminated a disastrous civil war, put down the Scottish invasion and reduced Ireland to obedience, but after the profitable Treaty of Etaples, remained on good terms with France, with the duchy of Brittany and with Spain, and was able to mollify Maximilian. With Maximilian's son, the archduke Philip, governor of the Netherlands, Henry made a special effort to keep peace because of the commercial advantages involved. With the papacy also his diplomacy and orthodoxy kept him in friendly relations. During the 24 years of Henry's reign only seven parliaments met, the second one instituting the famous court of the Star Chamber for the correction of irregularities in the administration of justice due to the breakdown of the jury system. The question of wages, hours of labour and standards of commerce and manufacture, were also taken up by parliament, and internal trade became less local. When Henry died his position was strong both in England and on the Continent.

See W. Campbell, *Materials for a Hist. of the Reign of Henry VII.* in *Rolls Series* (2 vols. 1873-77); Francis Bacon, *Life of Henry VII.* (ed. Lumby, Cambridge 1881); J. Gairdner, *Henry the Seventh* (1889); H. A. L. Fisher in vol. v. (2nd ed. 1913) of the *Political Hist.*

of England; A. F. Pollard, *The Reign of Henry VII. from Contemporary sources* (3 vols. 1913-14); Gladys Temperley, *Henry VII.* (1914) and W. D. Bushell, *The Lady Margaret Beaufort and Henry VII.* (1916).

HENRY VIII. (1491-1547), king of England and Ireland, the third child and second son of Henry VII. and Elizabeth of York, was born at Greenwich on June 28, 1491. He was the first English monarch to be educated under the influence of the Renaissance, and his tutors included the poet Skelton; he became an accomplished scholar, linguist, musician and athlete, and by the death of his brother Arthur in 1502 and of his father on April 22, 1509 Henry VIII. succeeded to the throne.

He had been betrothed to his brother's widow Catherine of Aragon, and in spite of the protest which he had been made to register against the marriage, and of the doubts expressed by Julius II. and Archbishop Warham as to its validity, it was completed in the first few months of his reign. This step was largely due to the pressure brought to bear by Catherine's father Ferdinand upon Henry's council; he regarded England as a tool in his hands and Catherine as his resident ambassador. The young king himself at first took little interest in politics, and for two years affairs were managed by the pacific Richard Fox (*q.v.*) and Warham. Then Wolsey became supreme, while Henry was immersed in the pursuit of sport and other amusements. He took, however, the keenest interest from the first in learning and in the navy, and his inborn pride easily led him to support Wolsey's and Ferdinand's war-like designs on France. He followed an English army across the Channel in 1513, and personally took part in the successful sieges of Thérouanne and Tournay and the battle of Guinegate which led to the peace of 1514. Ferdinand, however, deserted the English alliance, and amid the consequent irritation against everything Spanish, there was talk of a divorce between Henry and Catherine (1514), whose issue had hitherto been attended with fatal misfortune. But the renewed antagonism between England and France which followed the accession of Francis I. (1515) led to a rapprochement with Ferdinand; the birth of the lady Mary (1516) held out hopes of the male issue which Henry so much desired; and the question of a divorce was postponed. Ferdinand died in that year (1516) and the emperor Maximilian in 1519. Their grandson Charles V. succeeded them both in all their realms and dignities in spite of Henry's hardly serious candidature for the empire; and a lifelong rivalry broke out between him and Francis I. Wolsey used this antagonism to make England arbiter between them; and both monarchs sought England's favour in 1520, Francis at the Field of Cloth of Gold and Charles V. more quietly in Kent. At the conference of Calais in 1521 English influence reached its zenith; but the alliance with Charles destroyed the balance on which that influence depended. Francis was overweighted, and his defeat at Pavia in 1525 made the emperor supreme. Feeble efforts to challenge his power in Italy provoked the sack of Rome in 1527; and the peace of Cambrai in 1529 was made without any reference to Wolsey or England's interests.

Meanwhile Henry had been developing a serious interest in politics, and he could brook no superior in whatever sphere he wished to shine. He began to adopt a more critical attitude towards Wolsey's policy, foreign and domestic; and to give ear to the murmurs against the cardinal and his ecclesiastical rule. Parliament had been kept at arm's length since 1515 lest it should attack the church; but Wolsey's expensive foreign policy rendered recourse to parliamentary subsidies indispensable. When it met in 1523 it refused Wolsey's demands, and forced loans were the result which increased the cardinal's unpopularity. Nor did success abroad now blunt the edge of domestic discontent. His fate, however, was sealed by his failure to obtain a divorce for Henry from the papal court.

The king's hopes of male issue had been disappointed, and by 1526 it was fairly certain that Henry could have no male heir to the throne while Catherine remained his wife. There was Mary, but no queen regnant had yet ruled in England; Margaret Beaufort had been passed over in favour of her son in 1485, and there was a popular impression that women were excluded from the

throne. No candidate living could have secured the succession without a recurrence of civil war. Moreover the unexampled fatality which had attended Henry's issue revived the theological scruples which had always existed about the marriage; and the breach with Charles V. in 1527 provoked a renewal of the design of 1514. All these considerations were magnified by Henry's passion for Anne Boleyn, though she certainly was not the sole or the main cause of the divorce. That the succession was the main point is proved by the fact that Henry's efforts were all directed to securing a wife and not a mistress. Wolsey persuaded him that the necessary divorce could be obtained from Rome, as it had been in the case of Louis XII. of France and Margaret of Scotland. For a time Clement VII. was inclined to concede the demand, and Campeggio in 1528 was given ample powers. But the prospect of French success in Italy which had encouraged the pope proved delusive, and in 1529 he had to submit to the yoke of Charles V. This involved a rejection of Henry's suit, not because Charles cared anything for his aunt, but because a divorce would mean disinheriting Charles's cousin Mary, and perhaps the eventual succession of the son of a French princess to the English throne.

Wolsey fell when Campeggio was recalled, and his fall involved the triumph of the anti-ecclesiastical party in England. Laymen who had resented their exclusion from power were now promoted to offices such as those of lord chancellor and lord privy seal which they had rarely held before; and parliament was encouraged to propound lay grievances against the church. On the support of the laity Henry relied to abolish papal jurisdiction and reduce clerical privilege and property in England; and by a close alliance with Francis I. he insured himself against the enmity of Charles V. But it was only gradually that the breach was completed with Rome. Henry had defended the papacy against Luther in 1521 and had received in return the title "defender of the faith." He never liked Protestantism, and he was prepared for peace with Rome on his own terms. Those terms were impossible of acceptance by a pope in Clement VII.'s position; but before Clement had made up his mind to reject them, Henry had discovered that the papacy was hardly worth conciliating. His eyes were opened to the extent of his own power as the exponent of national antipathy to papal jurisdiction and ecclesiastical privilege; and his appetite for power grew. With Cromwell's help he secured parliamentary support, and its usefulness led him to extend parliamentary representation to Wales and Calais, to defend the privileges of Parliament, and to yield rather than forfeit its confidence. He had little difficulty in securing the Acts of Annates, Appeals and Supremacy which completed the separation from Rome, or the dissolution of the monasteries which, by transferring enormous wealth from the church to the crown, really, in Cecil's opinion, ensured the reformation.

The abolition of the papal jurisdiction removed all obstacles to the divorce from Catherine and to the legalization of Henry's marriage with Anne Boleyn (1533). But the recognition of the royal supremacy could only be enforced at the cost of the heads of Sir Thomas More, Bishop Fisher and a number of monks and others among whom the Carthusians signalized themselves by their devotion (1535-1536). Anne Boleyn fared no better than the Catholic martyrs; she failed to produce a male heir to the throne, and her conduct afforded a jury of peers, over which her uncle, the duke of Norfolk, presided, sufficient excuse for condemning her to death on a charge of adultery (1536). Henry then married Jane Seymour, who was obnoxious to no one, gave birth to Edward VI., and then died (1537). The dissolution of the monasteries had meanwhile evoked a popular protest in the north, and it was only by skilful and unscrupulous diplomacy that Henry was enabled to suppress so easily the Pilgrimage of Grace. Foreign intervention was avoided through the renewal of war between Francis and Charles; and the insurgents were hampered by having no rival candidate for the throne and no means of securing the execution of their programme.

Nevertheless their rising warned Henry against further doctrinal charges. He had authorized the English Bible and some approach towards Protestant doctrine in the Ten Articles. He also considered the possibility of a political and theological

alliance with the Lutheran princes of Germany. But in 1538 he definitely rejected their theological terms, while in 1539-1540 they rejected his political proposals. By the statute of Six Articles (1539) he took his stand on Catholic doctrine; and when the Lutherans had rejected his alliance, and Cromwell's nominee, Anne of Cleves, had proved both distasteful on personal grounds and unnecessary because Charles and Francis were not really projecting a Catholic crusade against England, Anne was divorced and Cromwell beheaded. The new queen Catherine Howard represented the triumph of the reactionary party under Gardiner and Norfolk; but there was no idea of returning to the papal obedience, and even Catholic orthodoxy as represented by the Six Articles was only enforced by spasmodic outbursts of persecution and vain attempts to get rid of Cranmer.

The secular importance of Henry's activity has been somewhat obscured by his achievements in the sphere of ecclesiastical politics; but no small part of his energies was devoted to the task of expanding the royal authority at the expense of temporal competitors. Feudalism was not yet dead, and in the north and west there were mediaeval franchises in which the royal writ and common law hardly ran at all. Wales and its marches were brought into legal union with the rest of England by the statutes of Wales (1534-1536); and after the Pilgrimage of Grace the Council of the North was set up to bring into subjection the extensive jurisdictions of the northern earls. Neither they nor the lesser chiefs who flourished on the lack of common law and order could be reduced by ordinary methods, and the Councils of Wales and of the North were given summary powers derived from the Roman civil law similar to those exercised by the Star Chamber at Westminster and the court of Castle Chamber at Dublin. Ireland had been left by Wolsey to wallow in its own disorder; but disorder was anathema to Henry's mind, and in 1535 Sir William Skeffington was sent to apply English methods and artillery to the government of Ireland. Sir Anthony St. Leger continued his policy from 1540; Henry, instead of being merely lord of Ireland dependent on the pope, was made by an Irish act of parliament king, and supreme head of the Irish church. Conciliation was also tried with some success; plantation schemes were rejected in favour of an attempt to Anglicize the Irish; their chieftains were created earls and endowed with monastic lands; and so peaceful was Ireland in 1542 that the lord-deputy could send Irish kerns and gallow-glasses to fight against the Scots.

Henry, however, seems to have believed as much in the coercion of Scotland as in the conciliation of Ireland. Margaret Tudor's marriage had not reconciled the realms; and as soon as James V. became a possible pawn in the hands of Charles V., Henry bethought himself of his old claims to suzerainty over Scotland. At first he was willing to subordinate them to an attempt to win over Scotland to his anti-papal policy, and he made various efforts to bring about an interview with his nephew. But James V. was held aloof by Beaton and two French marriages; and France was alarmed by Henry's growing friendliness with Charles V., who was mollified by his cousin Mary's restoration to her place in the succession to the throne. In 1542 James madly sent a Scottish army to ruin at Solway Moss; his death a few weeks later left the Scottish throne to his infant daughter Mary Stuart, and Henry set to work to secure her hand for his son Edward and the recognition of his own suzerainty. A treaty was signed with the Scottish estates; but it was torn up a few months later under the influence of Beaton and the queen-dowager Mary of Guise, and Hertford was sent in 1544 to punish this breach of promise by sacking Edinburgh.

Perhaps to prevent French intervention in Scotland Henry joined Charles V. in invading France, and captured Boulogne (Sept. 1544). But Charles left his ally in the lurch and concluded the peace of Cr py that same month; and in 1545 Henry had to face alone a French invasion of the Isle of Wight. This attack proved abortive, and peace between England and France was made in 1546. Charles V.'s desertion inclined Henry to listen to the proposals of the threatened Lutheran princes, and the last two years of his reign were marked by a renewed tendency to advance

in a Protestant direction. Catherine Howard had been brought to the block (1542) on charges in which there was probably a good deal of truth, and her successor, Catherine Parr, was a patroness of the new learning. An act of 1545 dissolved chantries, colleges and other religious foundations; and in the autumn of 1546 the Spanish ambassador was anticipating further anti-ecclesiastical measures. Gardiner had almost been sent to the Tower, and Norfolk and Surrey were condemned to death, while Cranmer asserted that it was Henry's intention to convert the mass into a communion service. An opportunist to the last, he would readily have sacrificed any theological convictions he may have had in the interests of national uniformity. He died on Jan. 28, 1547, and was buried in St. George's Chapel, Windsor.

The atrocity of many of Henry's acts, the novelty and success of his religious policy, the apparent despotism of his methods, or all combined, have made it difficult to estimate calmly the importance of Henry's work or the conditions which made it possible. Henry's egotism was profound, and personal motives underlay his public action. While political and ecclesiastical conditions made the breach with Rome possible—and in the view of most Englishmen desirable—Henry VIII. was led to adopt the policy by private considerations. He worked for the good of the state because he thought his interests were bound up with those of the nation; and it was the real coincidence of this private and public point of view that made it possible for so selfish a man to achieve so much for his country. The royal supremacy over the church and the means by which it was enforced were harsh and violent expedients; but it was of the highest importance that England should be saved from religious civil war, and it could only be saved by a despotic government. It was necessary for the future development of England that its governmental system should be centralized and unified, that the authority of the monarchy should be more firmly extended over Wales and the western and northern borders, and that the still existing feudal franchises should be crushed; and these objects were worth the price paid in the methods of the Star Chamber and of the Councils of the North and of Wales. Henry's work on the navy requires no apology; without it Elizabeth's victory over the Spanish Armada, the liberation of the Netherlands and the development of English colonies would have been impossible; and "of all others the year 1545 best marks the birth of the English naval power" (Corbett, *Drake*, i. 59). His judgment was more at fault when he conquered Boulogne and sought by violence to bring Scotland into union with England. But at least Henry appreciated the necessity of union within the British Isles; and his work in Ireland relaid the foundations of English rule. No less important was his development of the parliamentary system. Representation was extended to Wales, Cheshire, Berwick and Calais; and parliamentary authority was enhanced, largely that it might deal with the church, until men began to complain of this new parliamentary infallibility. The privileges of the two Houses were encouraged and expanded, and parliament was led to exercise ever wider powers. This policy was not due to any belief on Henry's part in parliamentary government, but to opportunism, to the circumstance that parliament was willing to do most of the things which Henry desired, while competing authorities, the church and the old nobility, were not. Nevertheless, to the encouragement given by Henry VIII. parliament owed not a little of its future growth, and to the aid rendered by parliament Henry owed his success.

He has been described as a "despot under the forms of law"; and it is apparently true that he committed no illegal act. His despotism consists not in any attempt to rule unconstitutionally, but in the extraordinary degree to which he was able to use constitutional means in the furtherance of his own personal ends. His industry, his remarkable political insight, his lack of scruple, and his combined strength of will and subtlety of intellect enabled him to utilize all the forces which tended at that time towards strong government throughout western Europe. In Michelet's words, "le nouveau Messie est le roi"; and the monarchy alone seemed capable of guiding the state through the social and political anarchy which threatened all nations in their transition from mediaeval to modern organization. The king was the emblem, the

focus and the bond of national unity; and to preserve it men were ready to put up with vagaries which to other ages seem intolerable. Henry could thus behead ministers and divorce wives with comparative impunity, because the individual appeared to be of little importance compared with the state. This impunity provoked a licence which is responsible for the unlovely features of Henry's reign and character. The elevation and the isolation of his position fostered a detachment from ordinary virtues and compassion, and he was a remorseless incarnation of Machiavelli's *Prince*. He had an elastic conscience which was always at the beck and call of his desire, and he cared little for principle. But he had a passion for efficiency, and for the greatness of England and himself. His mind, in spite of its clinging to the outward forms of the old faith, was intensely secular; and he was as devoid of a moral sense as he was of a genuine religious temperament. His greatness consists in his practical aptitude, in his political perception, and in the self-restraint which enabled him to confine within limits tolerable to his people an insatiable appetite for power.

BIBLIOGRAPHY.—The original materials for Henry VIII.'s biography are practically all incorporated in the monumental *Letters and Papers of the Reign of Henry VIII.* (21 vols.), edited by Brewer and Gairdner and completed after fifty years' labour in 1910. A few further details may be gleaned from such contemporary sources as Hall's *Chronicle*, Cavendish's *Life of Wolsey*, W. Thomas's *The Pilgrim* and others; and some additions have been made to the documentary sources contained in the *Letters and Papers* by recent works, such as Ehse's *Römische Dokumente*, and Merriman's *Life and Letters of Thomas Cromwell*. Lord Herbert of Cherbury's *Life and Reign of Henry VIII.* (1649), while good for its time, is based upon a very partial knowledge of the sources and somewhat antiquated principles of historical scholarship. Froude's famous portraiture of Henry is coloured by the ideas of hero-worship and history which the author imbibed from Carlyle, and the rival portraits in Lingard, R. W. Dixon's *Church History* and Gasquet's *Henry VIII. and the Monasteries* by strong religious feeling. A more discriminating estimate is attempted by H. A. L. Fisher in Messrs. Longmans' *Political History of England*, vol. v. (1906). See also C. Bémont, *Premier divorce de Henry VIII. et le Schisme d'Angleterre* (1917); Francis Hackett, *Henry the Eighth* (1929).

Of the numerous paintings of Henry none is by Holbein, who, however, executed the striking chalk-drawing of Henry's head, now at Munich, and the famous but decaying cartoon at Devonshire House. The well-known three-quarter length at Windsor, usually attributed to Holbein, is by an inferior artist. The best collection of Henry's portraits was exhibited at the Burlington Fine Arts Club in 1909, and the catalogue of that exhibition contains the best description of them; several are reproduced in Pollard's *Henry VIII.* (Goupil) (1902), the letterpress of which was published by Longmans in a cheaper edition (1905). Henry composed numerous state papers still extant; his only book was his *Assertio septem sacramentorum contra M. Lutherum* (1521), a copy of which, signed by Henry himself, is at Windsor. His songs and ballads were edited (1912) by Lady M. Trefusis for the Roxburghe Club.

HENRY I. (1008–1060), king of France, son of King Robert and his queen, Constance of Aquitaine, and grandson of Hugh Capet, succeeded his father in 1031, although in 1027 he had already been anointed king at Reims and associated in the government with his father. His mother formed a powerful league with her younger son Robert, against him, and he was forced to take refuge with Robert II., duke of Normandy. In the civil war which resulted, Henry finally defeated his opponents in 1032. Constance died in 1034, and Robert was given the duchy of Burgundy, thus founding that great collateral line which was to rival the kings of France for three centuries. From 1033 to 1043 Henry was involved in a life and death contest with those nobles whose territory adjoined the royal domains, especially with the house of Blois and the counts of Champagne. Henry's success was largely due to the help given him by Robert of Normandy, but upon the accession of Robert's son William (the Conqueror), Normandy itself became the chief danger. From 1047 until his death, Henry was almost constantly at war with William, who held his own against two royal invasions, in 1055 and 1058. Henry's reign marks the height of feudalism, Normandy, Champagne and Burgundy being only nominally subject to royal authority. Yet Henry maintained the independence of the clergy against the pope Leo IX., and claimed Lorraine from the emperor Henry III. In 1059 he had his eldest son Philip crowned as joint king, and died the following year. Henry married in 1043 Maud, niece of the emperor Henry III., who died childless in 1044. In 1051 Henry married the Rus-

sian princess Anne, daughter of Yaroslav I., grand duke of Kiev. She bore him two sons, Philip, his successor, and Hugh, count of Vermandois.

See the *Historiae* of Rudolph Glaber, edited by M. Prou (Paris, 1886); F. Sochnée, *Catalogue des actes d'Henri I^{er}* (1907); de Caiz de Saint Aymour, *Anne de Russie, reine de France* (1896); E. Lavisse, *Histoire de France*, tome ii. (1901), and the article on Henry I. in *La Grande Encyclopédie* by M. Prou.

HENRY II. (1519–1559), king of France, the second son of Francis I. and Claude, succeeded to the throne in 1547. When only seven years old he was sent by his father, with his brother the dauphin Francis, as a hostage to Spain in 1526, whence they returned after the conclusion of the peace of Cambrai in 1530. Henry was too young to have carried away any abiding impressions, yet throughout his life his character, dress and bearing were far more Spanish than French. In 1533 his father married him to Catherine de' Medici, and he became dauphin by the death of his elder brother Francis in 1536. From that time he was under the domination of Catherine, of Diane de Poitiers, and also of Duke Anne de Montmorency, his mentor. His younger brother, Charles of Orleans, was his father's favourite; and the rivalry of Diane and the duchesse d'Étampes widened the breach between the king and the dauphin. Henry supported the constable Montmorency when he was disgraced in 1541; protested against the treaty of Crépy in 1544; and at the end of the reign held himself completely aloof. After his accession in 1547 Diane, Montmorency and the Guises were all-powerful, and dismissed Cardinal de Tournon, de Longueval, the duchesse d'Étampes and all the late king's friends and officials. At that time Henry was twenty-eight years old. He was a robust man, and inherited his father's love of violent exercise; but his character was weak and his intelligence mediocre, and he had none of the superficial and brilliant gifts of Francis I. He was cold, haughty, melancholy and dull. He was a bigoted Catholic, and showed to the Protestants even less mercy than his father. During his reign the royal authority became more severe and more absolute than ever. Resistance to the financial extortions of the government was cruelly chastised, and the "Chambre Ardente" was instituted against the Reformers. Abroad, the struggle was continued against Charles V. and Philip II., which ended in the much-discussed treaty of Cateau-Cambrésis. Some weeks afterwards high feast was held on the occasion of the double marriage of the king's daughter Elizabeth with the king of Spain, and of his sister Margaret with the duke of Savoy. On June 30, 1559, when tilting with the count of Montgomery, Henry was wounded in the temple by a lance; he died on July 10. By his wife Catherine de' Medici he had seven children living: Elizabeth, queen of Spain; Claude, duchess of Lorraine; Francis (II.), Charles (IX.) and Henry (III.), all of whom came to the throne; Marguerite, who became queen of Navarre in 1572; and Francis, duke of Alençon and afterwards of Anjou, who died in 1584.

The bulk of the documents for the reign of Henry II. are unpublished, and are in the Bibliothèque Nationale, Paris. Of the published documents, see especially the correspondence of Catherine de' Medici (ed. by de la Ferrière, Paris, 1880), of Diane de Poitiers (ed. by Guiffrey, Paris, 1866), of Antoine de Bourbon and Jeanne d'Albret (ed. by Rochambeau, Paris, 1877), of Odet de Selve, ambassador to England (ed. by Lefèvre-Pontalis, Paris, 1888) and of Dominique du Gabre, ambassador to Venice (ed. by Vitalis, Paris, 1903); Ribier, *Lettres et mémoires d'état* (Paris, 1666); *Relations des ambassadeurs vénitiens*, etc. See also H. Lemonnier, "La France sous Henri II." (Paris, 1904), in the *Histoire de France*, by E. Lavisse, which contains a fuller bibliography of the subject.

HENRY III. (1551–1589), king of France, third son of Henry II. and Catherine de' Medici, was born at Fontainebleau on Sept. 19, 1551. As duke of Anjou, he won, under the direction of Tavannes, the battles of Jarnac and Moncontour over Condé and Coligny in 1569, and he assisted his mother in organizing the massacre (1572) of St. Bartholomew. He was Catherine's favourite son, and she now (1573) secured his election to the throne of Poland. But next year the death of his brother, Charles IX., brought him back post-haste to assume the crown of France. His accession meant a fresh lease of power for Catherine, from whose authority he never emancipated himself. His indolence and his vicious and corrupt life scandalized both the Huguenots and the

Catholic party. For the civil conflicts of his reign, see FRANCE: History.

A revolt (May 12, 1588) in Paris, the "day of the barricades," forced Henry to take refuge at Chartres. He then secured the murder of Henry of Guise and his brother, the cardinal, at Blois (Dec. 23, 1588). Early in January, Catherine de' Medici died. "Now I am king," cried Henry. But Paris was in the hands of the partisans of Guise, many of the provinces were in revolt, and Henry was driven into alliance with Henry of Navarre. Together they were investing Paris, when the Leaguers avenged the Guise murders through the instrumentality of a fanatic monk, Jacques Clément, who stabbed the king at an audience on Aug. 1, 1589. Henry died a few hours later, naming Henry of Navarre as his successor. By his wife, Louise de Mercoeur, he left no children, and with him the male line of the house of Valois became extinct.

See Correspondence of Catherine de' Medici and of Henry IV. (in the *Collection de documents inédits*), and of the Venetian ambassadors, etc.; P. Matthieu, *Histoire de France*, vol. i. (1631); Scipion Dupleix, *Histoire de Henri III.* (1633); Robiquet, *Paris et la Ligue* (1886); and J. H. Mariéjol, "La Réforme et la Ligue," in the *Histoire de France*, by E. Lavisse (Paris, 1904), which contains a more complete bibliography.

HENRY IV. (1553–1610), king of France, the son of Antoine de Bourbon, duke of Vendôme, head of the younger branch of the Bourbons, descendant of Robert of Clermont, sixth son of St. Louis, and of Jeanne d'Albret, queen of Navarre, was born at Pau (Basses Pyrénées) on Dec. 14, 1553. He was educated as a Protestant, and in 1557 was sent to the court at Amiens. In 1561 he entered the Collège de Navarre at Paris, returning in 1565 to Béarn. During the third war of religion in France (1568–1570) he was taken by his mother to Gaspard de Coligny, leader of the Protestant forces since the death of Louis I., prince of Condé, at Jarnac, and distinguished himself at the battle of Amay-le-Duc in Burgundy in 1569. On his mother's death in 1572 Henry became king of Navarre and married Margaret de Valois (*q.v.*) sister of Charles IX. of France. He escaped the massacre of St. Bartholomew by a feigned abjuration. On Feb. 2, 1576, after several vain attempts, he escaped from the court, joined the combined forces of Protestants and of opponents of the king, and obtained by the treaty of Beaulieu (1576) the government of Guienne. In 1577 he secured the treaty of Bergerac, which foreshadowed the edict of Nantes. As a result of quarrels with his wife, and the unwelcome intervention of Henry III., he undertook the seventh war of religion, seized Cahors on May 5, 1580, and signed the treaty of Fleix on Nov. 26, 1580. The death (1584) of the duke of Anjou, brother of King Henry III., made Henry of Navarre heir presumptive to the throne of France. Excluded from it by the treaty of Nemours (1585) he began the "war of the three Henrys" by a campaign in Guienne (1586) and defeated Anne, duc de Joyeuse, at Coutras on Oct. 20, 1587. Then Henry III., driven from Paris by the League on account of his murder of the duke of Guise at Blois (1588), sought the aid of the king of Navarre to win back his capital, recognizing him as his heir. The assassination of Henry III. on Aug. 1, 1589 left Henry king of France; but he had to struggle for ten more years against the League and against Spain before he won his kingdom. The main events in that long struggle were the victory of Arques (1589) over Charles, duke of Mayenne; of Ivry (1590); the siege of Paris (1590); of Rouen (1592); the meeting of the Estates of the League (1593), which the *Satire Ménippée* turned to ridicule; and finally the conversion of Henry IV. to Catholicism in July 1593—an act of political wisdom, since it brought about the collapse of all opposition. Paris gave in to him on March 22, 1594 and province by province yielded to arms or negotiations; while the victory of Fontaine-Française (1595) and the capture of Amiens forced Philip II. of Spain to sign the peace of Vervins on May 2, 1598. On April 13 of that year Henry IV. had promulgated the Edict of Nantes.

Then Henry set to work to pacify and restore prosperity to his kingdom. Convinced by the experience of the wars that France needed an energetic central power, he pushed at times his royal prerogatives to excess, raising taxes in spite of the Estates, interfering in the administration of the towns, reforming their consti-

tutions, and holding himself free to reject the advice of the notables if he consulted them. Aided by his faithful friend Maximilien de Béthune, baron de Rosny and duc de Sully (*q.v.*), he reformed the finances, repressed abuses, suppressed useless offices, extinguished the formidable debt and realized a reserve of eighteen millions. To alleviate the distress of the people he undertook to develop both agriculture and industry: planting colonies of Dutch and Flemish settlers to drain the marshes of Saintonge, issuing prohibitive measures against the importation of foreign goods (1597), introducing the silk industry, encouraging the manufacture of cloth, of glass-ware, of tapestries (Gobelins), and under the direction of Sully—named *grand-voyer de France*—improving and increasing the routes for commerce. A complete system of canals was planned, that of Briare partly dug. New capitulations were concluded with the sultan Ahmed I. (1604) and treaties of commerce with England (1606), with Spain and Holland. Attempts were made in 1604 and 1608 to colonize Canada (*see* CHAMPLAIN, SAMUEL DE). The army was reorganized, its pay raised and assured, a school of cadets formed to supply it with officers, artillery constituted and strongholds on the frontier fortified. While lacking the artistic tastes of the Valois, Henry beautified Paris, building the great gallery of the Louvre, finishing the Tuileries, building the Pont Neuf, the Hôtel-de-Ville and the Place Royale.

The foreign policy of Henry IV. was directed against the Habsburgs. Without declaring war, he did all possible harm to them by alliances and diplomacy. In Italy he gained the grand duke of Tuscany—marrying his niece Marie de' Medici in 1600—the duke of Mantua, the republic of Venice and Pope Paul V. The duke of Savoy, who had held back from the treaty of Vervins in 1598, signed the treaty of Lyons in 1601; in exchange for the marquisate of Saluzzo, France acquired Bresse, Bugey, Valromey and the bailliage of Gex. In the Low Countries, Henry sent subsidies to the Dutch in their struggle against Spain. He concluded alliances with the Protestant princes in Germany, with the duke of Lorraine, the Swiss cantons (treaty of Soleure, 1602) and with Sweden. In 1609, the opening of the question of the succession of John William the Good, duke of Cleves, of Jülich and of Berg, led Henry, in spite of his own hesitations and those of his German allies, to declare war on the emperor Rudolph II. But he was assassinated by Ravaillac (*q.v.*) on May 14, 1610, upon the eve of his great enterprise, leaving his policy to be followed up later by Richelieu. Sully in his *Économies royales* attributes to his master the "great design" of constituting, after having defeated Austria, a vast European confederation of fifteen states—a "Christian Republic"—directed by a general council of sixty deputies reappointed every three years. But this "design" has been attributed rather to the imagination of Sully himself than to the more practical policy of the king.

No figure in France has been more popular than that of "Henry the Great." He was affable, quick-witted, good-hearted and generally indulgent. His courage amounted almost to recklessness. He was a better soldier than strategist. Although at bottom authoritative he surrounded himself with admirable advisers (Sully, Sillery, Villeroy, Jeannin) and profited from their co-operation. His numerous love affairs (of which the most famous are those with Gabrielle d'Estrées and Henriette d'Entragues), did not affect his policy, in which he was guided only by an exalted ideal of his royal office, and by a certain sympathy—perhaps exaggerated in popular tradition—for the common people.

Henry IV. had no children by his first wife, Margaret of Valois. By Marie de' Medici he had Louis, later Louis XIII.; Gaston, duke of Orleans; Elizabeth, who married Philip IV. of Spain; Christine, duchess of Savoy; and Henrietta, wife of Charles I. of England. Among his bastards the most famous were the children of Gabrielle d'Estrées—Caesar, duke of Vendôme, Alexander of Vendôme, and Catherine Henriette, duchess of Elbeuf. Several portraits of Henry are preserved at Paris, in the Bibliothèque Nationale (*cf.* Bouchot, *Portraits au crayon*, p. 189), at the Louvre (by Probus, bust by Barthélemy Prieur) at Versailles, Geneva (Henry at the age of fifteen), at Hampton Court, at Munich and at Florence.

For the sources of the history of his reign *see* the *Recueil des lettres missives de Henri IV.*, published from 1839 to 1853 by B. de Xivrey, in the *Collection de documents inédits relatifs à l'histoire de France*, and the various researches of Galitzin, Bautiot, Halphen, Dussieux and others. Besides their historic interest, the letters written personally by Henry, whether love notes or letters of state, reveal a charming writer. Mention should be made of Auguste Poirson's *Histoire du règne de Henri IV.* (2nd ed., 4 vols., Paris, 1862-67) and of J. H. Mariéjol's volume (vi.) in the *Histoire de France*, edited by Ernest Lavisse (Paris, 1905), where main sources and literature are given with each chapter. A *Revue Henri IV.* has been founded at Paris (1905). Finally, a complete survey of the sources for the period 1494-1610 is given by Henri Hauser in vol. vii. of *Sources de l'histoire de France* (Paris, 1906) in continuation of A. Molinier's collection of the sources for French history during the middle ages.

HENRY I. (876?-936), surnamed the "Fowler," German king, son of Otto the Illustrious, duke of Saxony, shared in early life in various campaigns for the defence of Saxony. He married Hatburg, a daughter of Irwin, count of Merseburg, but as she had taken the veil on the death of a former husband this union was declared illegal by the church, and in 909 he married Matilda, daughter of a Saxon count named Thiederich, and a reputed descendant of the hero Widukind. On his father's death in 912 he became duke of Saxony, which he defended against the Slavs (*see* SAXONY). In 918 the German king Conrad I. advised the nobles to make the Saxon duke his successor. The Franks and the Saxons met at Fritzlar in May 919 and chose Henry as German king. The new king refused to allow his election to be sanctioned by the church. His authority, save in Saxony, was merely nominal; but he secured a recognition of his sovereignty from the Bavarians and the Swabians. In 921 Charles III. of France recognized Henry as king of the East Franks, and when in 923 the French king was taken prisoner by Herbert, count of Vermandois, Lorraine came under Henry's authority, and Gisbert, who married his daughter Gerberga, was recognized as duke. Henry reduced various Slavonic tribes in the east to subjection, took Brennibor, the modern Brandenburg, from the Hevelli, and secured both banks of the Elbe for Saxony. In 923 he had bought a truce for ten years with the Hungarians, by a promise of tribute, and on its expiration he gained two great victories over them in 933 at Jechaburg and Riade. The Danes were defeated, and territory as far as the Eider secured for Germany; and the king sought further to extend his influence by entering into relations with the kings of England, France and Burgundy. He died at Memleben on July 2, 936. By his first wife, Hatburg, he left a son, Thankmar, who was excluded from the succession as illegitimate; and by Matilda he left three sons, the eldest of whom, Otto (afterwards the emperor Otto the Great), succeeded him, and two daughters. Henry undertook only such enterprises as he was able to carry through. Laying more stress on his position as duke of Saxony than king of Germany, he conferred great benefits on his duchy. The founder of her town life and the creator of her army, he ruled in harmony with her nobles and secured her frontiers from attack.

See Widukind of Corvei, "Res gestae Saxonicae," ed. G. Waitz in the *Monumenta Germaniae historica. Scriptores*, Band iii. (Hanover and Berlin, 1826 seq.); "Die Urkunde des deutschen Königs Heinrichs I.," edited by T. von Sickingen in the *Monumenta Germaniae historica. Diplomata* (Hanover, 1879); W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit*, Bände i., ii. (Leipzig, 1881); G. Waitz, *Jahrbücher des deutschen Reichs unter König Heinrich I.* (Leipzig, 1885); and F. Löher, *Die deutsche Politik König Heinrich I.* (Munich, 1857).

HENRY VII. (1211-1242), German king, son of the emperor Frederick II. and his first wife Constance, daughter of Alphonso II., king of Aragon, was crowned king of Sicily in 1212 and made duke of Swabia in 1216. Pope Innocent III. had favoured his coronation as king of Sicily in the hope that the union of Sicily with the Empire would be dissolved, and had obtained a promise from Frederick to this effect. Nevertheless Henry was chosen king of the Romans, or German king, at Frankfurt in April 1220, and crowned at Aix-la-Chapelle on May 8, 1222 by his guardian Engelbert, archbishop of Cologne. He appears to have spent most of his youth in Germany, and in 1225 was married to Margaret (d. 1267), daughter of Leopold VI., duke of Austria. The murder of Engelbert in 1225 was followed by an increase of disorder in Germany, and in 1227 Henry took part in a quarrel which had

arisen on the death of Henry V., the childless count palatine of the Rhine. Relations between Frederick and his son began to be strained. The emperor had favoured the Austrian marriage because Margaret's brother, Duke Frederick II., was childless; but Henry took up a hostile attitude towards his brother-in-law and wished to put away his wife and marry Agnes, daughter of Wenceslaus I., king of Bohemia. In 1231 Henry refused to appear at the diet at Ravenna, and opposed the privileges granted by Frederick to the princes at Worms. In 1232 he submitted to his father, but in 1233 he issued a manifesto to the princes, and in 1234 raised the standard of revolt at Boppard. He succeeded in forming an alliance with the Lombards in December 1234, but his few supporters fell away when the emperor reached Germany in 1235, and, after a vain attack on Worms, Henry submitted and was kept for some time as a prisoner in Germany. His formal deposition as German king was not considered necessary, as he had broken the oath taken in 1232. He was removed to San Felice in Apulia, and afterwards to Martirano in Calabria, where he died, probably by his own hand, on Feb. 12, 1242. His two sons, Frederick and Henry, died in Italy about 1251.

See J. Rohden, *Der Sturz Heinrichs VII.* (Göttingen, 1883); F. W. Schirrmacher, *Die letzten Hohenstaufen* (Göttingen, 1871); E. Winkelmann, *Kaiser Friedrich II.* (Leipzig, 1889); P. Reinhold, *Die Empörung König Heinrichs gegen seinen Vater* (1911).

HENRY I. (c. 1210–1274), surnamed *le Gros*, king of Navarre and count of Champagne, was the youngest son of Theobald I. king of Navarre by Margaret of Foix, and succeeded his eldest brother Theobald III. as king of Navarre and count of Champagne in December 1270. His proclamation at Pamplona, however, did not take place till March of the following year, and his coronation was delayed until May 1273. At his death in 1274 the male line of the counts of Champagne and kings of Navarre became extinct. He married in 1269 Blanche, daughter of Robert, count of Artois, and niece of King Louis IX. and was succeeded by his only legitimate child, Jeanne or Joanna, by whose marriage to Philip IV. afterwards king of France in 1284, the crown of Navarre was united to that of France.

HENRY II. (1503–1555), titular king of Navarre, was the eldest son of Jean d'Albret (d. 1516) by his wife Catherine de Foix, sister and heiress of Francis Phoebus, king of Navarre, and was born at Sanquesa in April 1503. When Catherine died in exile in 1517 Henry succeeded her in her claim on Navarre, which was disputed by Ferdinand I. king of Spain; and under the protection of Francis I. of France he assumed the title of king. After ineffectual conferences at Noyon in 1516 and at Montpellier in 1518, an active effort was made in 1521 to establish him in the *de facto* sovereignty; but the French troops which had seized the country were ultimately expelled by the Spaniards. In 1525 Henry was taken prisoner at the battle of Pavia, but he contrived to escape, and in 1526 married Margaret, the sister of Francis I. and widow of Charles, duke of Alençon. By her he was the father of Jeanne d'Albret (d. 1572), and was consequently the grandfather of Henry IV. of France. Henry, who had some sympathy with the Huguenots, died at Pau on May 25, 1555.

HENRY I. (1512–1580), king of Portugal, third son of Emanuel the Fortunate, was born in Lisbon on Jan. 31, 1512. In 1532 he was made archbishop of Braga. In 1542 he received the cardinal's hat, and in 1578 when he was called to succeed his grand-nephew Sebastian on the throne, he held the archbishoprics of Lisbon and Coimbra as well as that of Braga, in addition to the wealthy abbacy of Alcobazar. As a sovereign he proved weak, timid and incapable. On his death in 1580, the male line of the royal family which traced its descent from Henry, first count of Portugal (c. 1100), came to an end.

HENRY, PRINCE OF BATTENBERG: see **BATTENBERG** and **MOUNTBATTEN**.

HENRY II. (1489–1568), duke of Brunswick-Wolfenbüttel, son of Duke Henry I., was born on Nov. 10, 1489. He began to reign in 1514, but his brother William objected to the indivisibility of the duchy which had been decreed by the elder Henry, and it was only in 1535, after an imprisonment of 11 years, that William recognized his brother's title. In 1525 he assisted Philip, land-

grave of Hesse, to crush the rising of the peasants in north Germany, and in 1528 took help to Charles V. in Italy, where he narrowly escaped capture. He joined the Catholic princes in concerting measures for opposing the Reformation. Henry was attacked by Luther with unmeasured violence in a writing *Wider Hanns Worst*. The duke soon came into collision with the Protestant towns of Goslar and Brunswick, against the former of which a sentence of restitution had been pronounced by the imperial court of justice (*Reichskammergericht*). Charles V. had suspended the execution of this sentence, a proceeding which Henry declared was *ultra vires*. The league of Schmalkalden, led by Philip of Hesse and John Frederick, elector of Saxony, took up arms to defend the towns; and in 1542 Brunswick was overrun and the duke forced to flee. In September 1545 he tried to regain his duchy, but was taken prisoner by Philip, and only released in April 1547. After his return to Brunswick he quarrelled with his subjects on political and religious questions, while his duchy was ravaged by Albert Alcibiades, prince of Bayreuth. Henry joined the league of princes against Albert, and after the death of Maurice, elector of Saxony, at Sievershausen in July 1553, he commanded the allied troops and defeated Albert in two engagements. In his later years he was reconciled with his Protestant subjects. He died at Wolfenbüttel on June 11, 1568. The duke was twice married, firstly in 1515 to Maria (d. 1541), sister of Ulrich of Württemberg, and secondly in 1556 to Sophia (d. 1575) daughter of Sigismund I., king of Poland. He had a romantic attachment to Eva von Trott, whom he represented as dead and afterwards kept concealed at Staufenburg. He was succeeded by his only surviving son, Julius (1528–1589).

See F. Koldewey, *Heinz von Wolfenbüttel* (Halle, 1883); and F. Bruns, *Die Vertreibung Herzog Heinrichs von Braunschweig durch den Schmalkaldischen Bund* (Marburg, 1889).

HENRY (1108?–1139), surnamed the "Proud," duke of Saxony and Bavaria, second son of Henry the Black, duke of Bavaria, and Wulfhild, daughter of Magnus Billung, duke of Saxony, was a member of the Welf family. His father and mother both died in 1126, and as his elder brother Conrad had entered the church, Henry became duke of Bavaria and shared the family possessions in Saxony, Bavaria and Swabia with his younger brother, Welf. In 1127 he married Gertrude, the only child of the German king, Lothair the Saxon, and at once took part in the warfare between the king and the Hohenstaufen brothers, Frederick II., duke of Swabia, and Conrad, afterwards the German king Conrad III. Simultaneously he suppressed a rising in Bavaria, led by Frederick, count of Bogen, during which both duke and count sought to establish their own candidates in the bishopric of Regensburg. Frederick submitted in 1133, and two years later the Hohenstaufen brothers made their peace with Lothair. In 1136 Henry accompanied Lothair to Italy, and taking command of one division of the German army marched into southern Italy, devastating the land as he went. It was probably about this time that he was invested with the margraviate of Tuscany and the lands of Matilda, the late margravine. After the Italian campaign Henry was appointed by the emperor as his successor in the dukedom of Saxony. When Lothair died in 1137 Henry's wealth and position made him a formidable candidate for the German throne; but his ambition aroused the jealousy of the princes, and prevented his election. The new king, Conrad III., demanded the imperial *insignia* which were in Henry's possession, and the duke in return asked for his investiture with the Saxon duchy. Conrad refused to assent on the pretext that it was unlawful for two duchies to be in one hand. Attempts at a settlement failed, and in July 1138 the duke was placed under the ban, and Saxony was given to Albert the Bear, afterwards margrave of Brandenburg. War broke out in Saxony and Bavaria, but was cut short by Henry's sudden death, whether by poison or not cannot be ascertained, at Quedlinburg on Oct. 20, 1139. Henry was a man of great ability, and his early death alone prevented him from playing an important part in German history.

See S. Riezler, *Geschichte Bayerns*, Band i. (Gotha, 1878); W. Bernhardt, *Lothar von Supplinburg* (Leipzig, 1879); W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit*, Band iv. (Brunswick, 1877); and A. L. Poole in *Cambridge Mediaeval History*, vol. v.

HENRY (1119-1195), surnamed the "Lion," duke of Saxony and Bavaria, only son of Henry the Proud, duke of Saxony and Bavaria, and Gertrude, daughter of the emperor Lothair the Saxon, was born at Ravensburg, and was a member of the family of Welf. In May 1142 Henry was invested as duke of Saxony at Frankfort, and Bavaria was given to Henry II., Jasomirgott, margrave of Austria, who married his mother. In 1147 Henry married Clementia, daughter of Conrad, duke of Zähringen (d. 1152). He made an expedition against the Abotrites, or Obotrites, in 1147, and won much land beyond the Elbe, in which were re-established the bishoprics of Mecklenburg, Oldenburg and Ratzeburg. Henry maintained, against Hartwig archbishop of Bremen, his right to invest these bishops, a privilege afterwards confirmed by the emperor Frederick I. In 1147 he made a formal claim on the duchy of Bavaria, and in 1151 made an unsuccessful attempt to take possession. The situation was changed in his favour when Frederick I. succeeded Conrad as German king in 1152. In 1154 he recognized the claim of Henry, who accompanied him on his first Italian campaign and suppressed a rising at Rome. Henry's formal investiture as duke of Bavaria took place in 1156. Two years later, Adolph II., count of Holstein, was compelled to cede Lübeck to him; campaigns in 1163 and 1164 broke the resistance of the Abotrites; and Saxon garrisons were established in the conquered lands. He had also helped Frederick I. in his expedition of 1157 against the Poles, and in 1159 had gone to his assistance in Italy.

In 1166 a coalition was formed against Henry at Merseburg under the leadership of Albert the Bear, margrave of Brandenburg, and Archbishop Hartwig. After indecisive fighting Frederick intervened, and made peace in 1168. Having obtained a divorce from his first wife in 1162, Henry was married in 1168 to Matilda (1156-89), daughter of Henry II. of England, and was soon afterwards sent by the emperor Frederick I. on an embassy to England and France. A war with Valdemar of Denmark, caused by a quarrel over the booty from the conquest of Rügen, lasted until 1171, when, in pursuance of a peace treaty Henry's daughter, Gertrude, married the Danish prince, Canute. During his pilgrimage to Jerusalem in 1172, Henry was received with great respect by the eastern emperor Manuel Comnenus at Constantinople.

A variety of reasons were leading to a rupture between Frederick and Henry, who showed little inclination to sacrifice his interests in Germany to help the imperial cause in Italy. He was displeased when his uncle, Welf, bequeathed his Italian and Swabian lands to the emperor, and the crisis came after Frederick's check before Alessandria in 1175. Henry declined to help the emperor in 1176, and though the peace of Venice provided for the restoration of Ulrich to his see of Halberstadt, Henry refused to give up the lands which he had seized belonging to the bishopric. This provoked a war in which Ulrich was joined by Philip, archbishop of Cologne. The dispute was to be settled at Worms, but Henry's failure to appear to answer the charges preferred against him, led to his being placed under the imperial ban at Würzburg in 1180, and deprived of his lands.

Meanwhile the war with Ulrich continued, but after his victory at Weissensee Henry's cause began to decline. When Frederick took the field in 1181, Henry sought peace. He was granted the counties of Lüneburg and Brunswick, but was banished under oath not to return without the emperor's permission. He went to Normandy, and afterwards to England, returning to Germany with Frederick's permission in 1185. He was soon regarded once more as a menace to peace, and of the three alternatives offered by the emperor in 1188 he rejected the idea of making a formal renunciation of his claim, or of participating in the crusade, and chose exile, going again to England in 1189. A few months later, he returned to Saxony, asserting that his lands had not been defended according to the emperor's promise. He found many allies, won Lübeck, and soon almost the whole of Saxony was in his power. King Henry VI. took the field against him, and in 1190 a peace was arranged at Fulda, by which he retained Brunswick and Lüneburg, received half the revenues of Lübeck, and gave two of his sons as hostages. In 1193 he revolted

against Henry VI., but the captivity of his brother-in-law Richard I., king of England, led to a reconciliation. Henry passed his later years in intellectual and artistic pursuits at Brunswick, where he died on Aug. 6, 1195. One of his sons was Otto, afterwards the emperor Otto IV., and another was Henry (d. 1227) count palatine of the Rhine.

Henry won his surname of "Lion" by his intrepidity. His influence on the fortunes of Saxony and northern Germany was considerable. He colonized the whole of northern Germany down to the Elbe; he founded numerous towns in Germany and sought to spread Christianity by introducing the Cistercians, founding bishoprics, and building churches and monasteries. Lane Poole, in the *Cambridge Medieval History* says of him, "He ruled an *imperium in imperio*, but he did not abuse his privileged position; his rule for the 20 years which followed the settlement of Ratisbon was beneficial to Germany, if it was detrimental to the interests of individual princes. Henry threw himself with all his energy into the work of German expansion, the promotion of commercial enterprise, the development of municipal life."

The authorities for the life of Henry the Lion are those dealing with the reign of the emperor Frederick I., and the early years of his son King Henry VI. The chief modern works are G. Prutz, *Heinrich der Löwe* (Leipzig, 1866); M. Philippson, *Geschichte Heinrichs des Löwen* (Leipzig, 1867, 2nd ed. 1918); and L. Weiland, *Das sächsische Herzogthum unter Lothar und Heinrich dem Löwen* (Greifswald 1866); F. Güterbock, *Der Prozess Heinrichs des Löwen* (1909); A. L. Poole, *Henry the Lion* (1912) and E. Gronen, *Die Machtpolitik H. des Löwen* (1919).

HENRY, JAMES (1798-1876), Irish classical scholar, was born in Dublin on Dec. 13, 1798 and died on July 14, 1876. His chief publication was the *Aeneidea* (1873-92), of which only the notes on the first book were published during the author's lifetime. As a textual critic Henry was exceedingly conservative.

See obituary notice by J. P. Mahaffy in the *Academy* of Aug. 12, 1876, where a list of his works, nearly all of which were privately printed, is given.

HENRY, JOSEPH (1797-1878), American physicist and scientific administrator, was born in Albany, N.Y., on Dec. 17, 1797, of Scottish ancestry. Henry attended a country district school to the age of 13; showing little interest in study, he was apprenticed to a watchmaker. A popular book on natural history picked up in his 16th year awoke his ambition, so that he resumed his education, attending Albany academy, teaching in country schools and tutoring to pay his way; completing the prescribed course, he continued his studies in chemistry, anatomy and physiology with a view to practising medicine. An unexpected appointment in 1825 to survey a route for a State road from the Hudson river to Lake Erie changed his goal to engineering, and it was with some reluctance that in 1826 he accepted an appointment to teach mathematics and natural philosophy in the Albany academy.

But his decision proved a most happy one. Beginning experiments in electromagnetism, Henry was the first to insulate wire for the magnetic coil; he invented the "spool" or "bobbin" winding; he discovered the necessary law of proportion between the electromotive force in the battery and the resistance of the magnet. He thus worked out for the first time the differing functions of two entirely different kinds of electromagnets; the one surrounded by numerous coils of no great length revolutionized the feeble electromagnet of Sturgeon. The other surrounded by a continuous coil of very great length made possible for the first time the transmission of a current over a great distance with little loss. Every electrical dynamo or motor uses the electromagnet in practically the form in which it was left by Henry in 1829. The principles involved in the "intensity" magnet constitute the indispensable basis of every form of the electromagnetic telegraph since invented, and Henry himself invented and demonstrated what appears to have been the first practical electromagnetic telegraph in 1830-31 at Albany. It consisted of a mile of copper bell-wire interposed in a circuit between a small Cruickshanks battery and an "intensity" magnet of continuous fine coil. A permanent magnet pivoted to swing hori-

zontally like the compass needle, was arranged so that one end remained in contact with a leg of the soft iron core, while the other end was near an office bell. At each excitation of the electromagnet the suspended magnet was repelled from one leg and attracted by the other, so that its free end tapped the bell. This was the first instance of magnetizing iron at a great distance, or of a suitable combination of magnet and battery being so arranged as to be capable of such action. Reporting his achievements in *Silliman's Journal* in 1831 Henry pointed out that the way was now clear for the invention of the commercial electromagnetic telegraph. In 1835, after his transfer to Princeton, he added a step in the invention of the "relay" by which a relatively feeble current operated an electromagnet which in turn controlled the local circuit of a more powerful magnet. This invention is extensively used in the field of electrical control, known as distant control. It was also in 1835 that Henry first used the earth as a return conductor. But in 1829 he had devised and constructed the first electromagnetic motor, an oscillating machine with automatic pole-changer, publishing a description of it in 1831. This machine was the forerunner of all electric motors. In the same period he made two other fundamental discoveries. The honour for the discovery of self-induction which he announced in 1832 has been universally conceded to him, and it was chiefly in recognition of this achievement that the International Congress of Electricians in Chicago in 1893 gave his name to the standard unit of inductive resistance. The other discovery, that of electromagnetic induction, was made independently and at the same period by both Henry and Faraday, and since the latter published first, the credit is rightfully given to him.

Professorship at Princeton.—In 1832 Henry was appointed to fill the chair of natural philosophy at Princeton. In addition to courses in physics and mathematics he lectured in chemistry, mineralogy, geology; later adding astronomy and architecture. Continuing his physical researches, he discovered that a current of low potential could induce a current of high potential by a suitable arrangement of the coils. He elucidated the laws upon which the electrical transformer of to-day is constructed. He found, also, that a second induced current could induce a third; the third a fourth; and so on, indefinitely; and that these currents could be induced at a distance. Some of his experiments in induction involved the transmission of electric force without wires through the floors and walls of buildings, and in one case he magnetized a needle by the transmission from a lightning flash 8 m. away. This appears to be the earliest record of the action of ether waves of the type employed in radio telegraphy and telephony to-day. The discovery of the oscillatory character of the electrical discharge came in 1842. Outside the field of electricity, Henry showed that liquids and solids generally have the same amount of cohesion. He showed, by means of a thermo-galvanometer, that sun spots radiate less heat than the general solar surface. He invented a new method for determining the velocity of projectiles. And in 1844 he presented a theoretical paper foreshadowing the principle of the conservation of energy.

Secretaryship at Smithsonian Institution.—In Dec. 1846 the second great period of Henry's life began with his election as first secretary of the newly formed Smithsonian Institution. The plan of organization which he drew up for it was so far beyond the average intelligence of his day as to meet with bitter opposition. But scientific men turned to the institution as a rallying and guiding centre. Under his leadership branches of science hitherto unworked in the United States were taken up; activity in all fields was tremendously stirred; scientific exploration was made a beneficiary of the military exploration and commercial exploitation of the West; the Government's support of scientific activity was enlisted and given direction.

Creation of U.S. Weather Service.—While at Albany he had devoted much attention to meteorology, realizing the need for much more data, and one of his first acts at the Smithsonian was to organize a corps of volunteer observers spread over the continent. He introduced standard instruments from abroad, prepared tables of instructions, and for 30 years maintained the investigations, collecting, reducing and publishing results which now

form a considerable portion of the foundation of meteorological science. In this connection he was the first to use the telegraph to transmit weather reports; the first to indicate daily atmospheric conditions on a map; the first to embrace a continent under a single system; the first to make weather forecasts from the data obtained. The success of the Smithsonian meteorological work resulted in the creation of the U.S. weather bureau.

A second main achievement while at the Smithsonian was to supply American science with the first great agency for free publication of results. Of almost equal importance was the system Henry inaugurated of distribution of these publications to libraries and scientific bodies throughout the world. This soon developed into the system of international exchanges by which scientific and later government publications were exchanged between the rest of the world and America through the Smithsonian.

Other Scientific Work.—In 1852 Henry became a member of the lighthouse board, serving as chairman from 1871 till his death. This gave him the incentive to make his classical researches on sound in relation to fog signalling which provided his country with the most serviceable system of fog signals known to maritime powers. His researches also enabled the Government to exchange sperm oil for lard oil and later lard oil for mineral oil as an illuminant, greatly increasing the efficiency of light beacons. He directed the mobilization of scientific effort during the Civil War and was a prime mover in the organization of the National Academy of Sciences of which he was the second president. He also took a leading part in the organization of the American Association for the Advancement of Science and of the Philosophical Society of Washington.

Henry was by general consent the foremost of American physicists; his influence, not only upon the development of scientific work in the United States, but upon its character, cannot be overestimated. He was a man of varied culture, of large breadth and liberality of views, of generous impulses, of great gentleness and courtesy of manner, combined with equal firmness of purpose and energy of action. He died in Washington on May 13, 1878. (C. G. A.)

HENRY, MATTHEW (1662–1714), English nonconformist divine, was born on the confines of Flintshire and Shropshire, on Oct. 8, 1662. He was the son of Philip Henry, who had, two months earlier, been ejected by the Act of Uniformity. In 1687 Matthew Henry became minister of a Presbyterian congregation at Chester, removing in 1712 to Mare street, Hackney. Two years later (June 22, 1714), he died suddenly at Nantwich. Henry's well-known *Exposition of the Old and New Testaments* (1708–10) is a commentary of a practical and devotional rather than of a critical kind.

See biographies by W. Tong (1816), C. Chapman (1859), J. B. Williams (1828, new ed. 1865); and M. H. Lee, *Diaries and Letters of Philip Henry* (1883).

HENRY, O. (1862–1910), American short-story writer, was born in Greensboro (N.C.), Sept. 11, 1862. His real name was William Sydney Porter. Until 15 he attended school. Then he served for five years as a clerk in his uncle's drug store. For his health he spent two years on a friend's ranch in La Salle county, Texas, absorbing the colour and robust life of the south-west. In 1884 he moved to Austin, Texas, where he worked as a book-keeper and then spent four years in the General Land Office. About the time of his marriage (1887) he began to send paragraphs and humorous sketches to newspapers. During 1891 he was teller in the First National Bank of Austin. In 1894 he bought Brann's *Iconoclast*, a satiric weekly, and transformed it into an extraordinarily humorous farrago of skit and burlesque, illustrated by himself; the venture was not a financial success, and in 1895 he joined the staff of the *Houston Post*, writing a daily column. In 1896 he was indicted on a charge of having embezzled funds (amounting to about \$1,150) from the bank in Austin. This affair has never been cleared up. While waiting for trial he had the first news of the acceptance of some of his stories by important magazines. In 1898 he was sentenced to five years' imprisonment in the Ohio penitentiary. His term was reduced to three years and three months for good behaviour. In

prison he seriously settled down to story-writing. In 1903 he contracted to do a short story a week for the *New York World*, at \$100 each. His first book, *Cabbages and Kings*, was published in 1904. In 1907 he married Sarah Coleman, a boyhood friend. He died in New York, June 5, 1910, and was buried in Asheville, North Carolina.

O. Henry's varied life is reflected in his stories. The extraordinary productivity of his eight years in New York brought him rapid fame, though he himself lived in seclusion. The sale of his books has been enormous, and they have been translated into many languages. The genial magic of his fine imagination, humour and brilliant narrative skill, triumph over the occasional journalism of his method, and he remains endlessly and enchantingly re-readable. His New York stories are the most famous, but it is probable that some of the southern and western tales, in which there is less strain for glittering effect, are of more lasting value. The tragedy of his own life taught him a chivalrous tenderness for the unlucky. Some of the greatest native endowments a writer can have were undeniably his; of him, as much as of any modern writer, it can be said that he had "no talent, only genius."

BIBLIOGRAPHY.—Published volumes by O. Henry include the following: *Cabbages and Kings* (1904); *The Four Million* (1906); *The Trimmed Lamp* (1907); *Heart of the West* (1907); *The Gentle Grafter* (1908); *The Voice of the City* (1908); *Roads of Destiny* (1909); *Options* (1909); *Whirligigs* (1910); *Let Me Feel Your Pulse* (1910); *The Two Women* (1910); *Strictly Business* (1910); *The Gift of the Wise Men* (1911); *Sixes and Sevens* (1911); *Rolling Stones* (1912); *Waifs and Strays* (1917); *O. Henryana* (1920); *Letters to Lithopolis* (1922); *Postscripts* (1923). His *Complete Writings* were published in 1917. See C. Alphonso Smith, *O. Henry* (1916) and "The Age of O. Henry" in F. L. Pattee, *Side-Lights on American Literature* (1922), also A. J. Jennings, *Through the Shadows with O. Henry* (1921). (C. M.)

HENRY, PATRICK (1736–1799), American politician and orator, was born at Studley, Hanover county, Va., on May 29, 1736. He was the son of John Henry, a well-educated Scotsman, who served in Virginia as county surveyor, colonel and judge of a county court. His mother was one of a family named Winston of Welsh descent, noted for conversational and musical talent. A mediocre student in the country school and under his father's tutorship, Patrick proved equally unsuccessful in business. In seven years he failed twice as a storekeeper and once as a farmer. In the meantime he acquired a taste for reading history and decided to study law. After a brief period of preparation he was admitted to the bar at the age of 24 and rapidly acquired a considerable practice. Then in 1763 was delivered his speech in "The Parson's Cause," a suit brought about by the custom of paying the clergy in money or tobacco according to the state of the market, which made Henry the idol of the common people of Virginia and procured for him an enormous clientele. In 1765 he was elected a member of the Virginia legislature, where he became in the same year the author of the "Virginia Resolutions," which, being no less than a declaration of resistance to the Stamp Act and an assertion of the right of the colonies to legislate for themselves independently of the control of the British parliament, gave a most powerful impetus to the movement resulting in the American Revolution. In a speech urging their adoption appear the often-quoted words, said to have been uttered in tones of thrilling solemnity, "Caesar had his Brutus, Charles the First his Cromwell, and George the Third (here he was interrupted by cries of 'Treason') and George the Third may profit by their example! If this be treason, make the most of it."

In the House of Burgesses he was prominent as a radical in all measures in opposition to the British Government, and was a member of the first Virginia committee of correspondence. In 1774 and 1775 he was a delegate to the continental congress. In 1775, in the second revolutionary convention of Virginia, Henry, regarding war as inevitable, presented resolutions for arming the Virginia militia, supporting them in a speech with the dramatic peroration, "I know not what course others may take, but as for me, give me liberty or give me death!" The resolutions were passed and their author was made chairman of the committee for which they provided. The chief command of the forces of Virginia was also given to him, but he was so checked by the Com-

mittee of Public Safety, that he resigned on Feb. 28, 1776. In the Virginia convention of 1776 he favoured the postponement of a declaration of independence until a firm union of the colonies and the friendship of France and Spain had been secured. In the same convention he served on the committee which drafted the first constitution for Virginia, and was elected governor of the State, being re-elected in 1777 and 1778, thus serving as long as the new constitution allowed any man to serve continuously. As governor he gave Washington able support and sent out the expedition under George Rogers Clark (*q.v.*) into the Illinois country.

In 1778 he was chosen a delegate to Congress, but declined to serve. From 1780 to 1784 and from 1787 to 1790 he was again a member of his State legislature; and from 1784 to 1786 was again governor. Until 1786 he was a leading advocate of a stronger central government, but when chosen a delegate to the Philadelphia constitutional convention of 1787, he declined to serve and he led the opposition to ratification in Virginia, contending that the proposed Federal Constitution was dangerous to the liberties of the country. This change of attitude is thought to have been due chiefly to his suspicion of the North aroused by John Jay's proposal to surrender to Spain for 25 or 30 years the navigation of the Mississippi. From 1794 until his death he declined in succession the following offices: U.S. senator (1794), secretary of State in Washington's cabinet (1795), chief justice of the U.S. Supreme Court (1795), governor of Virginia (1796), to which office he had been elected by the assembly, and envoy to France (1799). In 1799, however, he consented to serve again in his State legislature, where he wished to combat the Virginia Resolutions; he never took his seat, since he died, on his Red Hill estate, on June 6 of that year. Henry was twice married, first to Sarah Skelton and second to Dorothea Dandridge.

See M. C. Tyler, *Patrick Henry* (1887); and Wm. Wirt Henry (Patrick Henry's grandson), *Patrick Henry, Life, Correspondence and Speeches* (1890–91); these supersede the very unsatisfactory biography by William Wirt, *Sketches of the Life and Character of Patrick Henry* (1817). See also George Morgan, *The True Patrick Henry* (1907).

HENRY, VICTOR (1850–1907), French philologist, was born at Colmar in Alsace on Aug. 17, 1850. Having held appointments at Douai and Lille, he was appointed professor of Sanskrit and comparative grammar in the University of Paris. A prolific and versatile writer, he is probably best known by the English translations of his *Précis de Grammaire comparée de l'anglais et de l'allemand* and *Précis . . . du Grec et du Latin*. Important works by him on India and Indian languages are: *Manuel pour étudier le Sanscrit védique* (with A. Bergaigne, 1890); *Eléments de Sanscrit classique* (1902); *Précis de grammaire Pâlie* (1904); *Les Littératures de l'Inde: Sanscrit, Pâli, Prâcrit* (1904); *La Magie dans l'Inde antique* (1904); *Le Parsisme* (1905); *L'Agnistoma* (1906). Obscure languages (such as Innok, Quichua, Greenland) and local dialects (*Lexique étymologique du Breton moderne*; *Le Dialecte Alaman de Colmar*) also claimed his attention. *Le Langage Martien* is a curious book. It contains a discussion of some 40 phrases (amounting to about 300 words), which a certain Mademoiselle Hélène Smith (a well-known spiritualist medium of Geneva), while on a hypnotic visit to the planet Mars, learnt and repeated and even wrote down during her trance as specimens of a language spoken there, explained to her by a disembodied interpreter.

HENRY, WILLIAM (1775–1836), English chemist, son of Thomas Henry (1734–1816), an apothecary and writer on chemistry, was born at Manchester on Dec. 12, 1775. One of his best-known papers (*Phil. Trans.*, 1803) describes experiments on the quantity of gases absorbed by water at different temperatures and under different pressures, the conclusion he reached ("Henry's law") being that "water takes up of gas condensed by one, two or more additional atmospheres, a quantity which, ordinarily compressed, would be equal to twice, thrice, etc., the volume absorbed under the common pressure of the atmosphere." His *Elements of Experimental Chemistry* (1799) went through 11 editions in 30 years. He died at Pendlebury, near Manchester, on Sept. 2, 1836.

HENRYETTA, a city of Okmulgee county, Okla., U.S.A., 80m. E. of Oklahoma City, on Federal highways 75 and 266 and

served by the Frisco and the Kansas, Oklahoma and Gulf railways. It has a landing field for aeroplanes. In 1910 the population was 1,671; in 1920, 5,889 (92.6% native white), and in 1928 it was estimated locally at 13,000. The city is surrounded by oil and gas wells, coal and zinc mines, and farms producing chiefly cotton, corn, live stock, strawberries and other small fruits. Its industries include smelters, carbon and gasolene plants, and cotton gins. Henryetta was settled in 1901 and incorporated in 1903.

HENRY FITZ HENRY (1155–1183), second son of Henry II., king of England, by Eleanor of Aquitaine, became heir to the throne on the death of his brother William (1156), and at the age of five was married to Marguerite, the infant daughter of Louis VII. In 1170 he was crowned at Westminster by Roger of York. The protests of Becket against this usurpation of the rights of Canterbury were the ultimate cause of the primate's murder. The young king soon quarrelled with his father, who allowed him no power and a wholly inadequate revenue, and headed the great baronial revolt of 1173. He was assisted by his father-in-law, to whose court he had repaired; but, failing to shake the old king's power either in Normandy or England, made peace in 1174. Despite the generous terms which he received, he continued to intrigue with Louis VII., and was in consequence jealously watched by his father. In 1182 he and his younger brother Geoffrey took up arms, on the side of the Poitevin rebels, against Richard Coeur de Lion, apparently from resentment at the favour which Henry II. had shown to Richard in giving him the government of Poitou while they were virtually landless. Henry II. took the field in aid of Richard; but the young king and Geoffrey continued to aid the Aquitanian rising until the young king died (June 11, 1183). His death was bitterly regretted by his father. Though of a fickle and treacherous nature, he had all the personal fascination of his family, and is extolled by his contemporaries as a mirror of chivalry.

The original authorities for Henry's life are Robert de Torigni, *Chronica*; Giraldus Cambrensis, *De instructione principum*, *Guillaume le Maréchal* (ed. P. Meyer, Paris, 1891, etc.); Benedict, *Gesta Henrici*, William of Newburgh. See also Kate Norgate, *England under the Angevin Kings* (1887); Sir James Ramsay, *Angevin Empire* (1903); and C. E. Hodgson, *Jung Heinrich, König von England* (Jena, 1906).

HENRY OF ALMAIN (1235–1271), so called from his father's German connections, was the son of Richard, earl of Cornwall and king of the Romans. As a nephew of both Henry III. and Simon de Montfort he wavered between the two at the beginning of the Barons' War, but finally took the royalist side and was among the prisoners taken by Montfort at Lewes (1264). In 1268 he took the cross with his cousin Edward, who, however, sent him back from Sicily to pacify the unruly province of Gascony. Henry took the land route with the kings of France and Sicily. While attending mass at Viterbo (March 13, 1271) he was attacked by Guy and Simon de Montfort, sons of Earl Simon, and foully murdered. This revenge was the more outrageous since Henry had personally exerted himself on behalf of the Montforts after Evesham. The deed is mentioned by Dante, who put Guy de Montfort in the seventh circle of hell.

See W. H. Blaauw, *The Barons' War* (ed. 1871); Ch. Bémont, *Simon de Montfort* (1884).

HENRY OF BLOIS, bishop of Winchester (1101–1171), was the son of Stephen, count of Blois, by Adela, daughter of William I., and brother of King Stephen. Educated at Cluny, he was brought to England by Henry I. and made abbot of Glastonbury. In 1129 he was given the bishopric of Winchester and allowed to hold his abbey in conjunction with it. His hopes of the see of Canterbury were disappointed, but he obtained in 1139 a legatine commission which gave him a higher rank than the primate. Indeed, one of the ecclesiastical councils over which he presided formally declared that the election of the king in England was the special privilege of the clergy. Stephen owed his crown to Henry (1135), but they quarrelled when Stephen refused to give Henry the primacy; and the bishop took up the cause of Roger of Salisbury (1139). After the battle of Lincoln (1141) Henry declared for Matilda; but finding his advice treated with contempt, rejoined his brother's side, and his successful defence of Winchester against the empress (Aug.–Sept. 1141) was the

turning-point of the civil war. The expiration of his legatine commission in 1144 deprived him of much of his power. At the accession of Henry II. (1154) he retired from the world. He died in 1171.

HENRY OF GHENT (HENRICUS DE GANDAVO) (d. 1293), scholastic philosopher, known as "Doctor Solennis," was born in Ghent, where he studied before going to Cologne. In 1267 he was a canon of Tournai and in 1276 archdeacon of Bruges. By 1277 he was a master of theology at Paris, where he strongly opposed the mendicants.

Henry's philosophy, with its strong Augustinian colouring of peripatetic elements, closely resembles that of the early Franciscans. Thus, like them, he maintains that matter has its own actuality and by the Divine power could exist apart from form, that there is no real distinction between essence and existence or between the soul and its faculties, that a *forma corporeitatis* in man must be assumed if the independent natures of body and soul are to be ensured, that divine illumination is necessary for true knowledge, and that an eternal creation is impossible. Duns Scotus, whose formal distinction and voluntaristic leanings Henry anticipates, attacks his more original contributions, including his theory of negation as the principle of individuation, his rejection of the *species intelligibiles* in cognition, his stress on the activity of the intellect, his philosophy of conscience, and his theories that the Divine essence under a *relatio rationis* to a creature is the form in which God knows things and that creatures existed *secundum esse essentiae* in the Divine mind from all eternity.

BIBLIOGRAPHY.—Henry's *Quodlibeta* was published at Paris (1518) and at Venice (1608 and 1613), and his *Summa theologiae* at Paris (1520) and at Ferrara (1646). His *Comm. on the Physics*, his *Quaestiones on the Metaphysics* and a logical treatise are still in manuscript. The *De Scriptoribus ecclesiasticis* is probably not by him. See F. Ehrle, "Beitr. zu den Biographien berühmter Scholastiker" in *Archiv. für Lit. u. Kirchengeschichte des Mittelalters* (1885); H. Delehaye, *Nouvelles Recherches sur Henri de Gand* (1886); C. Werner, *Heinrich von Gent als Repräsentant des christlichen Platonismus* (Vienna, 1878); De Wulf, *Hist. de la phil. scholastique dans les Pays-Bas* (1895); G. Hagemann, *De Henrici Gandavensis quem vocant ontologismo* (1898); J. Lichteferd, *Die Ethik Heinrichs v. Gent* (1906); R. Braun, *Die Erkenntnislehre Heinrichs v. Gent* (1916).

HENRY OF HUNTINGDON, English chronicler of the 12th century, was born, apparently, between the years 1080 and 1090. At an early age Henry entered the household of Bishop Robert Bloet, who appointed him in 1110 archdeacon of Hertford and Huntingdon. Henry was on familiar terms with his patron; and also, it would seem, with Bloet's successor, by whom he was encouraged to undertake the writing of an English history from the time of Julius Caesar. This work, undertaken before 1130, was first published in that year; the author subsequently published in succession four more editions, of which the last ends in 1154 with the accession of Henry II. The only recorded fact of the chronicler's later life is that he went with Archbishop Theobald to Rome in 1139.

The *Historia Anglorum* was first printed in Savile, *Rerum Anglicarum scriptores post Bedam* (1596), given in *Monumenta historica Britannica*, vol. i. (ed. H. Petrie and Sharpe, London, 1848). The standard edition is that of T. Arnold in the Rolls Series (1879). There is a translation by T. Forester in Bohn's *Antiquarian Library* (1853). The *Historia* is of little independent value before 1126. Arnold prints, in an appendix, a minor work from Henry's pen, the *Epistola ad Walterum de contemptu mundi*, which was written in 1135. It is a moralizing tract, but contains some interesting anecdotes about contemporaries. A book, *De miraculis*, composed of extracts from Bede, was appended along with three epistles to the later recensions of the *Historia*. Henry composed eight books of Latin epigrams; two books survive in the Lambeth ms., No. 118.

HENRY OF LAUSANNE (variously known as of Bruys, of Cluny, of Toulouse, and as the Deacon), French heresiarch of the first half of the 12th century. Practically nothing is known of his origin or early life, but if St. Bernard's reproach (*Ep.* 241) be true, Henry was an apostate monk.

In 1134 Henry appeared before Innocent III. at the council

of Pisa, where he was compelled to abjure his errors and was imprisoned. Towards 1139, Peter the Venerable, abbot of Cluny, wrote his *Epistola seu tractatus adversus Petrobrusianos* (Migne, *Patr. Lat.* 189) against the disciples of Peter of Bruys and Henry of Lausanne, whom he calls Henry of Bruys, and whom, at the moment of writing, he accuses of preaching heresy in the south of France. In 1145, at the instance of the legate Alberic, St. Bernard set out for the heretical towns of Bergerac, Périgueux, Sarlat, Cahors and Toulouse. At his approach Henry quitted Toulouse, leaving Bernard by his eloquence and miracles to make many converts and to restore Toulouse and Albi to orthodoxy. After inviting Henry to a disputation, which he refused to attend, St. Bernard returned to Clairvaux. Soon afterwards the heresiarch was arrested, brought before the bishop of Toulouse, and probably imprisoned for life.

See E. Vacandard, "Les Origines de l'hérésie albigeoise," *Revue des questions historiques* (1894), and *Vie de S. Bernard* (vol. II., 1895).

HENRY OF PORTUGAL, surnamed the "Navigator" (1394-1460), duke of Viseu, governor of the Algarve, was born at Oporto on March 4, 1394. He was the third surviving son of John (João) I., the founder of the Aviz dynasty, under whom Portugal, victorious against Castile and against the Moors of Morocco, began to take a prominent place among European nations; his mother was Philippa, daughter of John of Gaunt. When Ceuta, the "African Gibraltar," was taken in 1415, Prince Henry performed the most distinguished service of any Portuguese leader, and received knighthood; he was now created duke of Viseu and lord of Covilham, and about the same time began his explorations, which, however, limited in their original conception, certainly developed into a search for a better knowledge of the western ocean and for a sea-way along the unknown coast of Africa to the supposed western Nile (our Senegal), to the rich negro lands beyond the Sahara desert, to the half-true, half-fabled realm of Prester John, and so ultimately to the Indies.

In 1415, the year of Ceuta, the prince sent out one John de Trasto on a voyage which brought the Portuguese to Grand Canary. There was no discovery here, for the whole Canarian archipelago was now well known to French and Spanish mariners. But in 1418 Zarco rediscovered Porto Santo, and in 1420 Madeira, which had originally been discovered in the 14th century. In 1424-25 Prince Henry attempted to purchase the Canaries, and began the colonization of the Madeira group, both in Madeira itself and in Porto Santo, for which he obtained charters (1430 and 1433) from the Portuguese Crown. In 1427, again, with his father King John, he sent out the pilot Diogo de Sevil, followed in 1431 by Gonçalo Velho Cabral, to explore the Azores. This rediscovery of the far western archipelago suggests that Henry had in mind the possibility of such a western route to Asia as Columbus attempted in 1492. Meantime, in 1418, Henry had gone in person to relieve Ceuta from an attack of Morocco and Granada Mussulmans; had accomplished his task, and had planned, though he did not carry out, a seizure of Gibraltar. At this time, it is probable that he was gathering information from the Moors with regard to the coast of "Guinea" and the interior of Africa. In 1419, after his return to Portugal, he was created governor of the "kingdom" of Algarve, the southernmost province of Portugal; and his connection now began with what afterwards became known as the "Infante's Town" (*Villa do Infante*) at Sagres, close to Cape St. Vincent; where, before 1438, a *Tercena Nabal* or naval arsenal grew up and where, from 1438, after the Tangier expedition, the prince often resided.

In 1433 King John died, exhorting his son not to abandon his schemes; and in 1434 one of Henry's ships, commanded by Gil Eannes, at length doubled Cape Bojador. In 1435 Baldaya, the prince's cup-bearer, passed 50 leagues beyond; and by 1436 the Portuguese had almost reached Cape Blanco. Plans of further conquest in Morocco, resulting in 1437 in the disastrous attack upon Tangier, and followed in 1438 by the death of King Edward (Duarte) and the domestic troubles of the minority of Affonso V., now interrupted Atlantic and African exploration down to 1441, except in the Azores, where rediscovery and colonization progressed, as is shown by the royal licence of July 2, 1439, to

people "the seven islands" of the group then known. In 1441 exploration began again in earnest with the venture of Antam Gonçalves, who brought to Portugal the first slaves and gold-dust from the Guinea coasts beyond Bojador; while Nuno Tristam in the same year pushed on to Cape Blanco. These successes produced a great effect; the cause of discovery became popular; and many volunteers, especially merchants and seamen from Lisbon and Lagos, came forward. In 1442 Nuno Tristam reached the Bay or Bight of Arguim, where the infante erected a fort in 1448, and where for years the Portuguese carried on vigorous slave-raiding. Meantime the prince, who was now a knight of the Garter of England, proceeded with his Sagres buildings, which formed the nucleus of the "Infante's Town," and which had been begun about 1437.

In 1444-46 there was a burst of maritime and exploring activity; more than 30 ships sailed with Henry's licence to Guinea; and several of their commanders achieved notable success. Thus Diniz Díaz, Nuno Tristam, and others reached the Senegal in 1445; Díaz rounded Cape Verde in the same year; and in 1446 Alvaro Fernandez pushed on almost to our Sierra Leone, to a point 110 leagues beyond Cape Verde. This was perhaps the most distant point reached before 1461. In 1444, moreover, the island of St. Michael in the Azores was sighted (May 8), and in 1445 its colonization was begun. During this latter year also Juan Fernandez (*q.v.*) spent seven months among the natives of the Arguim coast, and brought back the first trustworthy first-hand European account of the Sahara hinterland. Slave-raiding continued ceaselessly; by 1446 the Portuguese had carried off nearly a thousand captives from the newly surveyed coasts; but between this time and the voyages of Cadamosto (*q.v.*) in 1455-1456, the prince altered his policy, forbade the kidnapping of the natives and endeavoured to promote their peaceful intercourse with his men. In 1445-46, again, Dom Henry renewed his earlier attempts to purchase or seize the Canaries, which brought Portugal to the verge of war with Castile; but the home Government refused to support him, and the project was again abandoned. Azurara's narrative ceases in 1448; one of the latest expeditions noticed by him is that of a foreigner in the prince's service, "Vallarte the Dane," which ended in destruction near the Gambia, after passing Cape Verde in 1448. After this the chief matters in Dom Henry's life are, first, the progress of discovery and colonization in the Azores; secondly, the rapid progress of civilization in Madeira, evidenced by its timber, sugar, corn and honey, and above all by its wine; and thirdly, the explorations of Cadamosto and Diogo Gomez (*q.v.*).

Cadamosto in 1455 and 1456, explored part of the courses of the Senegal and the Gambia, discovered the Cape Verde islands (1456), named and mapped more carefully than before a considerable section of the coast beyond Cape Verde, and gave much new information on the trade-routes of north-west Africa and on the native races; while Gomez, in his first important venture (after 1448 and before 1458), though not accomplishing the full Indian purpose of his voyage (he took a native interpreter with him for use "in the event of reaching India"), explored and observed in the Gambia valley and along the adjacent coasts with fully as much care and profit. As a result of these expeditions the infante seems to have sent out in 1458 a mission to convert the Gambia negroes. Gomez' second voyage, resulting in another "discovery" of the Cape Verde islands, was probably in 1462, after the death of Prince Henry; it is likely that among the infante's last occupations were the necessary measures for the equipment and despatch of this venture, as well as of Pedro de Sintra's important expedition of 1461.

The infante's share in home politics was considerable, especially in the years of Affonso V.'s minority (1438, etc.) while his elder brother Pedro was regent. When Dom Pedro rose in revolt (1447), Henry stood by the king and allowed his brother to be crushed. In the Morocco campaigns of his last years, especially at the capture of Alcazar the Little (1458), he restored his military fame which brought him invitations from the pope, the emperor and the kings of Castile and England, to take command of their armies. The prince was also grand master of the Order of Christ, the

successor of the Templars in Portugal; and most of his Atlantic and African expeditions sailed under the flag of his order, whose revenues were at the service of his explorations, in whose name he asked and obtained the official recognition of Pope Eugenius IV. for his work, and on which he bestowed privileges in the new lands. As "protector of Portuguese studies," Dom Henry founded a professorship of theology, and perhaps also chairs of mathematics and medicine, in Lisbon. To instruct his captains, pilots and other pioneers more fully in the art of navigation and the making of maps and instruments he procured the aid of one Master Jacome from Majorca, together with that of certain Arab and Jewish mathematicians. We hear also of one Master Peter, who inscribed and illuminated maps for the infante; the mathematician Pedro Nunes declares that the prince's mariners were well taught and provided with instruments and rules of astronomy and geometry "which all map-makers should know"; Cadamosto tells us that the Portuguese caravels in his day were the best sailing ships afloat; while, from several matters recorded by Henry's biographers, it is clear that he devoted great attention to the study of earlier charts and of any available information he could gain upon the trade-routes of north-west Africa. Thus we find an Oran merchant corresponding with him about events happening in the negro-world of the Gambia basin in 1458. Even if there were never a formal "geographical school" at Sagres, or elsewhere in Portugal, founded by Prince Henry, it appears certain that his court was the centre of active and useful geographical study, as well as the source of the best practical exploration of the time.

The prince died on Nov. 13, 1460, in his town near Cape St. Vincent, and was buried in the church of St. Mary in Lagos, but a year later his body was removed to the superb monastery of Batalha. His great-nephew, King Dom Manuel, had a statue of him placed over the centre column of the side gate of the church of Belem, and in 1840 a monument was erected to him at Sagres.

HENRY RASPE (1202?-1247), German king and landgrave of Thuringia, was the second surviving son of Hermann I., landgrave of Thuringia, and Sophia, daughter of Otto I., duke of Bavaria. When his brother the landgrave Louis IV. died in Italy in 1227, Henry seized the government of Thuringia and expelled his brother's widow, St. Elizabeth of Hungary, and her son Hermann. With some trouble Henry made good his position, although his nephew Hermann II. was nominally the landgrave until his death in 1242. In 1236 Henry accompanied the emperor Frederick II. on a campaign against Frederick II., duke of Austria, and took part in the election of his son Conrad as German king at Vienna in 1237. But he did not appear at the diet of Verona in 1238; possibly he disliked the betrothal of his nephew Hermann to the emperor's daughter Margaret. At all events, when the projected marriage had been broken off the landgrave supported the emperor in 1239 in opposition to a plan formed by various princes to elect an anti-king. In 1241 Henry's loyalty again wavered, and he was himself mentioned as a possible anti-king. Frederick's visit to Germany in 1242 prevented this step for a time. In April 1246 Pope Innocent IV. wrote to the German princes advising them to choose Henry as their king in place of Frederick who had

just been declared deposed. Henry was elected at Veitshöchheim on May 22, 1246, and became known as the *Pfaffenkönig*, or parsons' king. Collecting an army, he defeated King Conrad near Frankfort on Aug. 5, 1246, and then, after holding a diet at Nuremberg, undertook the siege of Ulm. He died at the Wartburg on Feb. 17, 1247. Henry married Gertrude, sister of Frederick II., duke of Austria, but left no children, and on his death the male line of his family became extinct.

See T. Knochenhauer, *Geschichte Thüringens zur Zeit des ersten Landgrafenhauses* (Gotha, 1871); and R. Malsch, *Heinrich Raspe, Landgraf von Thüringen und deutscher König* (1911).

HENRYSON, ROBERT (fl. 1470-1500), Scottish poet, was born probably about 1425. It has been surmised that he was connected with the family of Henderson of Fordell, but of this there is no evidence. He is described, on the title-page of the 1570 edition of his *Fables*, as "scholemaister of Dunfermeling," probably of the grammar school of the Benedictine abbey there. As Dunbar (*q.v.*) refers to him as deceased in his *Lament for the Makaris*, his death may be dated about 1500.

Henryson's longest, and in many respects his most original and effective work, is his *Morall Fabillis of Esope*, a collection of 13 fables, chiefly based on the versions of Anonymus, Lydgate and Caxton. The outstanding merit of the work is its freshness of treatment. The old themes are retold with such vivacity, such fresh lights on human character, and with so much local "atmosphere," that they deserve the credit of original productions. They are certainly unrivalled in English fabulistic literature. The earliest available texts are the Charteris text printed by Lekpreuik in Edinburgh in 1570 and the Harleian ms. No. 3,865 in the British Museum.

In the *Testament of Cresseid* Henryson supplements Chaucer's tale of Troilus with the story of the tragedy of Cresseid. Here again his literary craftsmanship saves him from the disaster which must have overcome another poet in undertaking to continue the part of the story which Chaucer had intentionally left untold. The description of Cresseid's leprosy, of her meeting with Troilus, of his sorrow and charity, and of her death, give the poem a high place in writings of this genre.

The poem entitled *Orpheus and Eurydice*, which is drawn from Boethius, contains some good passages, especially the lyrical lament of Orpheus, with the refrains "Quhar art thou gane, my luf Erudices?" and "My lady quene and luf, Erudices." It is followed by a long *moralitas*, in the manner of the *Fables*.

Thirteen shorter poems have been ascribed to Henryson. Of these the pastoral dialogue "Robene and Makyne," perhaps the best known of his work, is the most successful. Its model may perhaps be found in the *pastourelles*, but it stands safely on its own merits.

The ms. authorities for the text are the Asloan, Bannatyne, Maitland Folio, Makculloch, Gray and Riddell. *The Testament of Cresseid* was printed by the Cambridge University Press (1926). The best edition, containing all the texts, is that of the Scottish Text Society (ed. G. Gregory Smith), the first volume of the text (vol. ii. of the work) appearing in 1906, vol. iii. in 1908, and vol. i., with an introduction, in 1914. *The Poems of Robert Henryson*, a revised text with notes and introduction, was edited by W. M. Metcalfe (Paisley, 1917).

HENSCHEL, SIR GEORGE (Isidor Georg) (1850-), English musician (naturalized 1890), of German family, was born at Breslau, and educated as a pianist, making his first public appearance in Berlin in 1862. He subsequently, however, took up singing, having developed a fine baritone voice. In 1877 he began a successful career in England and in 1881 he married the American soprano, Lillian Bailey (d. 1901), who was associated with him in a number of vocal recitals. He was also prominent as a conductor, started the London Symphony Concerts in 1886 and both in England and America (where he was the first conductor of the Boston Symphony Concerts, 1881) he did admirable work in this way, giving programmes always of the highest type. In 1907 he married as his second wife, Amy Louis, also a musician, of New York, while he continued singing and teaching until long past his 70th year. Among his compositions may be mentioned a fine *Stabat Mater* (Birmingham Festival 1894), an opera *Nubia* (Dresden, 1899) and many admirable songs.

See Sir George Henschel, *Musings and Memories of a Musician* (1918).

HENSELT, ADOLF VON (1814-1889), German composer, was born at Schwabach, Bavaria, May 12, 1814. When three years old he began to learn the violin, and at five the pianoforte under Frau v. Fladt. With financial help from King Louis I. he went to study under Hummel in Weimar, and thence in 1832 to Vienna, where, besides studying composition under Simon Sechter, he made a great success as a concert pianist. In 1837 he settled at Breslau, where he had married, but in the following year he migrated to St. Petersburg, where he became court pianist, acquired a great position, and was ennobled. He died at Warmbrunn, Silesia, on Oct. 10, 1889. The characteristic of Henselt's playing was a combination of Liszt's sonority with Hummel's smoothness and he was justly regarded as one of the greatest pianists of his time. His best known works are the concerto in F minor and a number of charming studies and salon pieces.

HENSLOW, JOHN STEVENS (1796-1861), English botanist and geologist, was born at Rochester on Feb. 6, 1796. He was educated at St. John's college, Cambridge, and in 1819, during a tour in the Isle of Wight with Adam Sedgwick, developed an interest in geology. His paper on the geology of the Isle of Man appeared in *Trans. Geol. Soc.* (1821), and on the geology of parts of Anglesey in *Trans. of the Cambridge Philosophical Society* (1821), a society founded by Sedgwick and Henslow. In 1822 Henslow became professor of mineralogy at Cambridge, and two years later took holy orders. In the following year he resigned the chair of mineralogy to succeed to that of botany. To him Darwin largely owed his attachment to natural history, and also his introduction to Captain Fitzroy of H.M.S. "Beagle." In 1832 Henslow was appointed vicar of Cholsey-cum-Moultsford, Berkshire, and in 1837 rector of Hitcham, Suffolk. Henslow died at Hitcham on May 16, 1861. His publications included *A Catalogue of British Plants* (1829; 2nd ed., 1835); *Principles of Descriptive and Physiological Botany* (1835); *Flora of Suffolk* (1860, with E. Skepper).

See the *Memoir*, by L. Jenyns (1862).

HENSLOWE, PHILIP (d. 1616), English theatrical manager, was the son of Edmund Henslowe of Lindfield, Sussex, master of the game in Ashdown forest and Broil park. He appears to have been in the service of the bailiff to Viscount Montague, and settled in Southwark before 1577. He married the bailiff's widow, and, with the fortune he got with her, he became a considerable owner of Southwark property. He started his connection with the stage when he bought (March 24, 1584) land near the southern end of Southwark bridge, on which stood the Little Rose playhouse, afterwards rebuilt as the Rose. Successive companies played in it under Henslowe's financial management between 1592 and 1603. The theatre at Newington Butts was also under him in 1594. A share of the control in the Swan theatre, which like the Rose was on the Bankside, fell to Henslowe before the close of the 16th century. With the actor Edward Alleyn, who married his step-daughter Joan Woodward, he built in Golden lane, Cripplegate Without, the Fortune playhouse, opened in Nov. 1600. In Dec. 1594 they had secured the Paris garden, a place for bear-baiting, on the Bankside, and in 1604 they bought the office of master of the royal game of bears, bulls and mastiffs from the holder, and obtained a patent. Alleyn sold his share to Henslowe in Feb. 1610, and three years later Henslowe formed a new partnership with Jacob Meade and built the Hope playhouse, designed for stage performances as well as bull and bear-baiting, and managed by Meade.

In the theatres in which Henslowe had a share were first produced many plays by the famous Elizabethan dramatists. His relations to the companies who acted in his theatres were very complicated. In the case of the "Admiral's Men" he was not their manager or director, but practically their banker, in which capacity he probably influenced policy and certainly had a hold on playwrights and actors to whom he made advances. What is known as "Henslowe's Diary" contains some accounts referring to Ashdown forest between 1576 and 1581, entered by John Henslowe, while the later entries by Philip Henslowe from 1592 to 1609 are

a principal source of information for the theatrical history of the time, and for the biography of individual playwrights and actors.

"Henslowe's Diary" passed into the hands of Edward Alleyn, and thence into the Library of Dulwich college, where the manuscript remained intact for more than 150 years. In 1780 Malone tried to borrow it, but it had been mislaid; in 1790 it was discovered and given into his charge. He was then at work on his *Variorum Shakespeare*. Malone had a transcript made of certain portions, and collated it with the original; and this transcript, with various notes and corrections by Malone, is now in the Dulwich library. An abstract of this transcript he also published with his *Variorum Shakespeare*. The ms. of the diary was eventually returned to the library in 1812 by Malone's executor. In 1840 it was lent to J. P. Collier, who in 1845 printed for the Shakespeare Society what purported to be a full edition, but it was afterwards shown by G. F. Warner (*Catalogue of the Dulwich library*, 1881) that a number of forged interpolations have been made, the responsibility for which rests on Collier.

See *Henslowe's Diary*, ed. J. P. Collier (Shakespeare Soc., 1845); *Henslowe's Diary*, ed. W. W. Greg (1904-08); *Henslowe Papers, being Documents Supplementary to Henslowe's Diary*, ed. W. W. Greg (1907); E. K. Chambers, *The Elizabethan Stage* (vol. i., 1923).

HENSON, HERBERT HENSLEY (1863-), English divine, was born in London on Nov. 8, 1863. As an unattached student at Oxford he graduated in 1884 and was elected a fellow of All Souls college. He was ordained in 1887, and after being head of Oxford House at Bethnal Green for a year, he was given the living of Barking, Essex. He was incumbent of St. Mary's hospital, Ilford 1895-1900, canon of Westminster and rector of St. Margaret's 1900-12, and dean of Durham 1912-18, when he was promoted to the bishopric of Hereford in succession to Dr. Percival. Owing to his pronounced liberal opinions in theology, and to his insistence on the validity of Nonconformist orders, his elevation to the bench of bishops aroused some controversy. In 1920 he was translated to the bishopric of Durham.

HENTY, GEORGE ALFRED (1832-1902), English war-correspondent and author, was born at Trumpington, near Cambridge, and educated at Westminster school and Caius college, Cambridge. He served in the Crimea in the Purveyor's department, and after the peace filled various posts in the department in England and Ireland, but he found the routine little to his taste, and drifted into journalism for the London *Standard*. He volunteered as special correspondent for the Austro-Italian War of 1866, accompanied Garibaldi in his Tirolese campaign, followed Lord Napier through the mountain gorges to Magdala, and Lord Wolsley across bush and swamp to Kumasi. Next he reported the Franco-German War, starved in Paris through the siege of the Commune and then turned south to rough it in the Pyrenees during the Carlist insurrection. He was in Asiatic Russia at the time of the Khiva expedition, and later saw the desperate hand-to-hand fighting of the Turks in the Serbian war. He found his real vocation in middle life, when he began to write excellent books of adventure for boys, many of which had a good historical background. His first boys' book *Out on the Pampas* dates from 1868; the last two, posthumously published, were *With Kitchener to the Sudan* (1903), and *With the Allies to Peking* (1904). There are some 80 of these stories. Henty died on board his yacht in Weymouth harbour on Nov. 16, 1902.

HENWOOD, WILLIAM JORY (1805-1875), English mining geologist, was born at Perron Wharf, Cornwall, on Jan. 16, 1805. He was assay-master and supervisor of tin in the duchy of Cornwall from 1832 to 1838. In 1840 he was elected F.R.S. In 1843 he went to take charge of the Gongo-Soco mines in Brazil; afterwards he proceeded to India to report on certain metalliferous deposits for the Indian Government. The mineral Henwoodite was named after him. He died at Penzance on Aug. 5, 1875.

HENZADA, a town and district of Lower Burma, formerly in the Pegu, but now in the Irrawaddy division. Area, 2,872 sq.m. Pop. (1921) 550,920. The district lies to the west of the Irrawaddy and stretches to the crest of the Arakan Yomas which forms the boundary between Henzada and the Sandoway district

of Arakan. The district thus comprises a tract of hilly, forested country on the west and a portion of the plain of the Irrawaddy on the east. The town of Henzada itself is usually regarded as lying at the southern end of the Irrawaddy valley proper and at the head of the delta. The low-lying eastern portions of the district are protected from inundation by immense embankments, so that almost the whole is suitable for rice cultivation. Tobacco is also an important crop. The hills in the western part are forested. The chief town of the district is Henzada, which had in 1921 a population of 23,651. Other towns in the district are Myan-aung, with a population of 7,793; and Kyangin with a population of 7,064 according to the 1921 census. The river towns are served by the steamers of the Irrawaddy Flotilla Company and a branch of the Burma Railway runs from Kyangin to Henzada and from Henzada to Bassein.

The district was once a portion of the Talaing kingdom of Pegu, afterwards annexed to the Burmese empire in 1753, and has no history of its own.

HEPATICA (*Hepatica americana*), a North American plant of the buttercup family (Ranunculaceae), called also liverleaf, liverwort and squirrel-cup, native in woods from Nova Scotia to Manitoba and south to Florida and Missouri. It is a low, almost stemless perennial, about 3 in. high, often growing in tufts, with thick, evergreen, three-lobed basal leaves on very hairy stalks, and delicate blue, purple or white flowers, about $\frac{3}{8}$ in. broad, composed of 6 to 12 sepals, and borne singly on hairy stalks. Immediately beneath the flower are three leaflets (involucre) simulating a calyx. The very similar sharp-lobed hepatica (*H. acutiloba*), with pointed instead of rounded leaf lobes, found from Quebec to Minnesota and south in the Alleghanies to Georgia and in the interior to Missouri, is rare or absent near the Atlantic coast. The hepaticas are among the earliest and best-known woodland wild flowers of eastern North America, the two species occurring together in many localities. The leaves that last over winter are deep olive green or bronzy above and reddish-purple or liver-coloured beneath. By some botanical authorities the genus *Hepatica* is included in the genus *Anemone*. The Old World hepatica or liverleaf (*Hepatica triloba* or *Anemone Hepatica*), widely distributed in Asia and Europe, and often cultivated, is not found native in the British Isles. (See ANEMONE; RANUNCULACEAE.)

BY COURTESY OF WILD FLOWER PRESERVATION SOCIETY

HEPATICA (HEPATICA AMERICANA), OFTEN CALLED LIVER-LEAF, BECAUSE OF ITS ROUND-LOBED LEAF, SOMEWHAT RESEMBLING A LIVER

HEPATOSCOPY, one of the oldest and most widespread methods of divining the future, both among primitive people and among several of the civilizations of antiquity, was by the reading of omens in the signs noted on the liver of the animal offered as a sacrifice to some deity. In ancient Babylonia it can be traced back to the 3rd millennium B.C. From the Etruscans it made its way to the Romans. Among the Greeks it was introduced at a very early period and persisted to a late day. It is still found in S.E. Asia, Borneo and in Africa.

The rite everywhere rests on the belief that the liver was at one time regarded as the seat of vitality. Filled with blood it was natural to regard it as the seat of the blood, which was everywhere in antiquity associated with life. It was a natural and short step to identify the liver with the soul as well as with the seat of life, and therefore as the centre of all manifestations of vitality and activity.

The theory underlying hepatoscopy consists of the belief (1) that the liver is the seat of life, or the soul of the animal; and (2) that the liver of the sacrificial animal, by virtue of its acceptance on the part of the god, took on the same character as the soul of the god to whom it was offered. If, therefore, one understood the signs noted on a particular liver, one entered, as it were, into

the mind (as one of the manifestations of soul-life) of the deity who had assimilated the being of the animal to his own being. To know the mind of the god was equivalent to knowing what the god in question proposed to do. Hence, when one approached a deity with an enquiry as to the outcome of some undertaking, the reading of the signs on the liver afforded a direct means of determining the course of future events, which was, according to current beliefs, in the control of the gods. Hepatoscopy represents the starting-point for the study of animal anatomy in general. We find in the Babylonian-Assyrian omen-texts special designations for the three main lobes of the sheep's liver; the groove separating the right lobe into two sections; the two appendixes attached to the upper lobe or *lobus pyramidalis*; the gall-bladder; and the cystic duct (compared, apparently, to a "penis") to which it is joined, as well as the hepatic duct (pictured as an "outlet") and the *ductus choleductus*, the depression separating the two lower lobes from the *lobus caudatus* and known as the *porta hepatis*. Lastly, to pass over unnecessary details, the markings of various kinds observed on the lobes of the livers of freshly slaughtered animals, which are due mainly to the traces left by the subsidiary hepatic ducts and hepatic veins on the liver surface, also had their special designations. The constantly varying character of these markings (no two livers being alike in this respect) furnished a particularly large field for the fancy of the *bārū*-priest. In the interpretation of these signs the two chief factors were association of ideas and association of words. For example, a long cystic duct would point to a long reign of the king. If the gall-bladder was swollen, it pointed to an extension or enlargement of some kind. If the *porta hepatis* was torn it prognosticated a plundering of the enemy's land. As among most people, a sign on the right side was favourable, but the same sign on the left side unfavourable. Past experience constituted an important factor in establishing the interpretation of signs noted. If, for example, on a certain occasion when the liver of a sacrificial animal was examined, certain events of a favourable character followed, the conclusion was drawn that the signs observed were favourable, and hence the recurrence of these signs on another occasion suggested a favourable answer to the question put to the priests. With this in view, omens given in the reigns of prominent rulers were preserved with special care as guides to the priests. In the course of time the collections of signs and their interpretation made by the *bārū*-priests grew in number until elaborate series were produced in which the endeavour was made to exhaust, so far as possible, all the varieties and modifications of the many signs, so as to furnish a complete handbook both for purposes of instruction and as a basis for the practical work of divination.

HEPBURN, SIR JOHN (c. 1598–1636), Scottish soldier in the Thirty Years' War, was a son of George Hepburn of Athelstaneford near Haddington. In 1620 and in the following years he served in Bohemia, on the lower Rhine and in the Netherlands, and in 1623 he entered the service of Gustavus Adolphus, who, two years later, appointed him colonel of a Scottish regiment of his army. He took part with his regiment in Gustavus's Polish wars, and in 1631, a few months before the battle of Breitenfeld he was placed in command of the "Scots" or "Green" brigade of the Swedish army. At Breitenfeld it was Hepburn's brigade which delivered the decisive stroke. He remained with Gustavus until the battle of the Alte Veste near Nuremberg. He then entered the French service, and raised two thousand men in Scotland for the French army, to which force was added in France the historic Scottish archer bodyguard of the French kings. The Royal Scots (Lothian) regiment (late 1st Foot) represents in the British army of to-day Hepburn's French regiment, and indirectly, through the amalgamation referred to, the Scottish contingent of the Hundred Years' War. Hepburn's claim to the right of the line of battle was bitterly resented by the senior French regiments. In 1633, Hepburn took part in the campaigns in Alsace and Lorraine (1634–36). In 1635 Bernhard of Saxe-Weimar, on entering the French service, brought with him Hepburn's former Swedish regiment, which was at once amalgamated with the French "régiment d'Hébron," the latter thus attaining the unusual strength of 8,300 men. Sir John Hepburn was killed at the siege of Saverne on

July 8, 1636. He was buried in Toul cathedral. Hepburn was a sincere Roman Catholic, and is said to have left Gustavus owing to a jest about his religion.

See James Grant, *Memoirs of Sir John Hepburn* (1851).

HEPHAESTION, a Macedonian general, celebrated as the friend of Alexander the Great, who called Hephaestion his Patroclus. In the later campaigns in Bactria and India, he superintended the founding of cities and colonies, and built the fleet intended to sail down the Indus. He was rewarded with a golden crown and the hand of Drypetis, the sister of Alexander's wife Stateira (324 B.C.). In the same year he died suddenly at Ecbatana. Mourning was ordered throughout Asia; at Babylon a funeral pile was erected and temples were built in his honour (see ALEXANDER THE GREAT).

HEPHAESTION, a grammarian of Alexandria who flourished in the age of the Antonines. His manual of Greek metres (*Ἑγχειρίδιον περὶ μέτρων*), which he abridged from his larger work, is the only complete treatise on the subject that has been preserved. The concluding chapter (*Περὶ ποιήματος*) discusses the various kinds of poetical composition. It is written in a simple style, and was much used as a school-book.

Editions by T. Gaisford (1835, with the valuable scholia), R. Westphal (1886, in *Scriptores metrici Graeci*) and M. Consruch (1906); translation by T. F. Barham (1843); see also W. Christ, *Gesch. der griech. Litt.* (1898); M. Cornsbruch, *De veterum Περὶ ποιήματος doctrina* (1890); J. E. Sandys, *Hist. Class. Schol.* (1921), i.

HEPHAESTUS (Gr. *Hēphaistos*), in Greek mythology, the god of fire. As the distribution of his shrines testifies, he was originally a deity of that Anatolian population known to the Greeks as Carians. The home of his worship seems to have been the Lycian Olympus, where a quantity of natural gas still escapes from the soil. This was in antiquity "at once the sanctuary and the image" of the god (Max. Tyr. *Dissert.* ii., 8). Hence the cult spread to other places in Asia Minor and to some islands, especially Lemnos and Moschylus, which it reached very early. Hephaestus became the god of fire in general, and consequently the divine smith and patron of craftsmen. His cult reached Athens not later than about 600 B.C., and was carried at an early but unknown date to the volcanic Liparaean Islands off Sicily, whence it spread sporadically to Sicily and Campania. Crete it never reached, and Greece proper, with the exception of Attica, hardly at all. Natural fires, volcanic or gaseous, were often considered to be the workshops of Hephaestus.

In Homer the fire-god was the son of Zeus and Hera, cast out from heaven, either by Zeus, when he fell on Lemnos, or by Hera, who threw him down immediately after his birth in disgust at his lameness, when he was received by the sea-goddesses Eurynome and Thetis (*Iliad*, i. 590; xviii. 395).

The subsequent return of Hephaestus to Olympus is a favourite theme in early art. His wife was Charis, (in the *Iliad*) or Aphrodite (in the *Odyssey*). The connexion of the rough Hephaestus with these goddesses is curious; it may be due to the beautiful works (*χαριέντα έργα*) of the smith-god, but it is possibly derived from the supposed fertilizing and productive power of fire, in which case Hephaestus is a natural mate of Charis, a goddess of spring, and Aphrodite, the goddess of love. In Homer, the skill of Hephaestus in metallurgy is often mentioned; his forge was on Olympus, where he was served by images of golden handmaids that he had animated. Similar myths are found in relation to the Finnish smith-god Ilmarinen and the Teutonic Wieland; a belief in the magical power of metal-workers is a common survival from an age in which their art was new and mysterious. In epic poetry Hephaestus is rather a comic figure, and his limping gait provokes "Homeric laughter" among the gods. It has been suggested that in an early stage of society the trade of a smith would be suitable for the lame; Hephaestus and the lame Wieland would thus conform to the type of their human counterparts.

At Athens, with its large industrial population, Hephaestus was an important god. He finds a place in the local myths (see ERECHTHEUS). His temple has been identified, not improbably, with the so-called "Theseum." It contained a statue of Athena,

and the two deities are often associated, in literature and cult, as the joint givers of civilization to the Athenians. The class of artisans was under their special protection; and the joint festival of the two divinities—the *Chalceia*—commemorated the invention of bronze-working by Hephaestus. In the *Hephaisteia* (the particular festival of the god) there was a torch race, a ceremonial not indeed confined to fire-gods like Hephaestus and Prometheus, but probably in its origin connected with them, whether its object was to purify and quicken the land, or (according to another theory) to transmit a new fire with all possible speed to places where the fire was polluted. The relation between Hephaestus and Prometheus is in some respects close, though the distinction between these gods is clearly marked. The fire, as an element, belongs to the Olympian Hephaestus; the Titan Prometheus, a more human character, steals it for the use of man. Prometheus resembles the Polynesian Maui, who went down to fetch fire from the volcano of Mahuika, the fire-god. Hephaestus is a culture-god mainly in his secondary aspect as the craftsman, whereas Prometheus originates all civilization with the gift of fire. But Prometheus despite his Greek name, in actual cult, was largely superseded by Hephaestus.

In archaic art Hephaestus is generally represented as bearded, though occasionally a younger beardless type is found, as on a vase (in the British Museum), on which he appears as a young man assisting Athena in the creation of Pandora. At a later time the bearded type prevails. The god is usually clothed in a short sleeveless tunic and wears a round close-fitting cap. His face is that of a middle-aged man, with unkempt hair. He is in fact represented as an idealized Greek craftsman, with the hammer, and sometimes the pincers. In art no attempt was made, as a rule, to indicate the lameness of Hephaestus; but one sculptor (Alcamenes) is said to have suggested the deformity without spoiling the statue.

See L. R. Farnell, *Cults of the Greek States*, v. (1909); and the classical dictionaries, especially L. Malten in Pauly-Wissowa, s.v. (1912). See also VULCAN.

HEPPENHEIM, a town of Germany, in the republic of Hesse, on the Bergstrasse, between Darmstadt and Heidelberg, 21 m. N. of the latter by rail. Pop. (1925) 7,693. The ruins of the castle of Starkenburg, built by the abbot, Ulrich von Lorsch, about 1064 and destroyed during the Seven Years' War, are near. Hops, wine and tobacco are grown, and there are large stone quarries, and several small industries in the town.

HEPPLEWHITE, GEORGE (d. 1786), one of the most famous English cabinet-makers of the 18th century. The only certain facts known about him are that he was apprenticed to Gillow at Lancaster, that he carried on business in the parish of St. Giles, Cripplegate, and that administration of his estate was granted to his widow Alice on June 27, 1786. After his death the business was continued by his widow under the style of A. Hepplewhite and Co. Our only approximate means of identifying his work are *The Cabinet-Maker and Upholsterer's Guide*, first published in 1788, and ten designs in *The Cabinet-maker's London Book of Prices* (1788), issued by the London Society of Cabinet-Makers. It is, however, exceedingly difficult to earmark any given piece of furniture as being the actual work or design of Hepplewhite, since to a very large extent the name represents rather a fashion than a man. Lightness, delicacy and grace are the distinguishing characteristics of Hepplewhite work, which depended for its effect more upon inlay than upon carving. If Hepplewhite was not the originator he appears to have been the most constant and successful user of the shield back for chairs. Where Chipendale had used the cabriole and the square leg with a good deal of carving, the Hepplewhite manner preferred a slighter leg, plain, fluted or reeded, tapering to a spade foot which often became the "spider leg" that characterized much of the late 18th-century furniture; this form of leg was not confined to chairs but was used also for tables and sideboards. Hepplewhite, or those who worked with him, appears to have originated, or at all events popularized, the winged easy-chair, in which the sides are continued to the same height as the back. The backs of Hepplewhite chairs were

often adorned with galleries and festoons of wheat-ears or pointed fern leaves, and not infrequently with the prince of Wales's feathers in some decorative form. It has been objected as an artistic flaw in Hepplewhite's chairs that they have the appearance of fragility. They are, however, constructionally sound as a rule. The painted and japanned work has been criticized on safer grounds. This delicate type of furniture, often made of satinwood, and painted with wreaths and festoons, with amorini and musical instruments or floral motives, has no elements of decorative permanence. With comparatively little use the paintings wear off and have to be renewed. A large proportion of Hepplewhite furniture is inlaid with the exotic woods which had come into high favour by the third quarter of the 18th century.

It was not in chairs alone that the Hepplewhite manner excelled. It made, for instance, a speciality of seats for the tall, narrow Georgian sash windows. These window-seats had ends rolling over outwards, and no backs, and display an elegant simplicity. Elegance, in fact, was the note of a style which on the whole was more distinctly English than that which preceded or immediately followed it. The smaller Hepplewhite pieces are much prized by collectors. Among these may be included urn-shaped knife-boxes in mahogany and satinwood, charming in form and decorative in the extreme; inlaid tea-caddies, varying greatly in shape and material; delicate little fire-screens with shaped poles; painted work-tables, and inlaid stands. Hepplewhite's bedsteads with carved and fluted pillars were very handsome and attractive. If we were dealing with a less elusive personality it would be just to say that Hepplewhite's work varies from the extreme of elegance and the most delicious simplicity to an unimaginative commonplace, and sometimes to actual ugliness. As it is, this summary may well be applied to the style as a whole—a style which was assuredly not the creation of any one man, but owed much alike of excellence and of defect to a school of cabinet-makers who were under the influence of conflicting tastes and changing ideals. See references under FURNITURE, EUROPEAN.

HEPTARCHY, a word which is frequently used to designate the period of English history between the coming of the Anglo-Saxons in 449 and the supremacy established by Egbert of Wessex early in the ninth century. It is derived from Gr. *ἑπτα*, seven, and *ἀρχή* rule, and was first used during the 16th century because of the belief held by Camden and other older historians, that during this period there were exactly seven kingdoms in England, *i.e.*, Northumbria, Mercia, East Anglia, Essex, Kent, Sussex, and Wessex. This belief is erroneous, as the number of kingdoms varied considerably from time to time; nevertheless the word still serves a useful purpose to denote the period.

HEPTASTYLE, an architectural term applied to a building or colonnade with seven columns in front.

HERA, in Greek mythology, the sister and wife of Zeus and queen of the Olympian gods; she was identified by the Romans with Juno. The derivation of the name is obscure and it seems likely that she is a pre-hellenic deity. Various ancient and modern theorists identify her with the air, earth, or moon. Whatever may have been her origin, to the historic Greeks (except a few poets or philosophers) she was a purely anthropomorphic goddess. In literature, from the times of Homer and Hesiod, she played an important part, appearing most frequently as the jealous and resentful wife of Zeus. In this character she pursues with vindictive hatred the heroines, such as Alcmena, Leto, and Semele, who were beloved by Zeus, and also their children. This character belongs to literature rather than to cult, in which the dignity and power of the goddess is naturally more emphasized.

The worship of Hera is found, in different degrees of prominence, throughout the Greek world. It was especially important in the ancient centres, Argos, Mycenae and Sparta, which she claims in the *Iliad* (iv. 51.) as her three dearest cities. Whether Hera was also worshipped by the early Dorians is uncertain; after the Dorian invasion she remained the chief deity of Argos, but her cult at Sparta was not so conspicuous. She received honour, however, in other parts of the Peloponnese, in central Greece, and in the islands, particularly Samos, where, according to the local tradition, she was born. As Hera Lacinia (from her Lacinian

temple near Croton) she was extensively worshipped in Magna Graecia.

The connection of Zeus and Hera was probably not primitive, since Dione seems to have preceded Hera as the wife of Zeus at Dodona. But it certainly is early. The close relation of the two deities appears in a frequent community of altars and sacrifices, and also in the *ἱερός γάμος*, a dramatic representation of their sacred marriage. For instance, at the Daedala, as the festival was

HERA, OR JUNO, QUEEN OF THE GODS, DESCENDING FROM OLYMPUS. A Roman statue found in the Villa Albani, in Rome

called at Plataea, an effigy was made from an oak-tree, dressed in bridal attire, and carried in a cart with a woman who acted as bridesmaid. The image was called Daedale, and the ritual was explained by a myth: Hera had left Zeus in her anger; in order to win her back, Zeus announced that he was about to marry, and dressed up a puppet to imitate a bride; Hera met the procession, tore the veil from the false bride, and, on discovering the ruse, became reconciled to her husband. The image was put away after each occasion; every 60 years a large number of such images, which had served in previous celebrations, were carried in procession to the top of Mount Cithaeron and were burned on an altar together with animals and the altar itself. As Frazer notes (*Golden Bough* [3rd ed.] ii. 140, *et seq.*; cf. Nilsson in *Journ. Hell. Stud.* xliii. 144), this festival appears to belong to the large class of mimetic charms designed to quicken the growth of vegetation; the marriage of Zeus and Hera would, in this case, represent the union of the king and queen of May. But it by no means follows that Hera was therefore originally a goddess of the earth or of vegetation, for we have no proof that she or Zeus had originally anything to do with it. At Samos the image of Hera was annually concealed on the seashore and solemnly discovered. There is nothing here to suggest a marriage of heaven and earth, or of two vegetation-spirits; as Dr. Farnell points out, the ritual appears to connect with certain local marriage customs. It is at least remarkable that, except at Argos, Hera had little to do with agriculture, and was not closely associated with such deities as Cybele, Demeter, Persephone, and Dionysus, whose connection with the earth, or with its fruits, is beyond doubt.

In her general cult Hera was worshipped in two main capacities: (1) as the consort of Zeus and queen of heaven; (2) as the goddess who presided over marriage, and, in a wider sense, over the various phases of a woman's life. The marriage-goddess naturally became the protectress of women in child-bed, and bore the title of the birth-goddess (*Eileithyia*), at Argos and Athens. In Homer (*Il.* xi. 270) and Hesiod (*Theog.* 922) she is the mother of the *Eileithyiai*, or the single *Eileithyia*. Her cult-titles *παρθένος* (or *παῖς*), *τέλεια* and *χήρα* the "maiden," "wife," and "widow" (or "divorced") express the different conditions in the lives of her human worshippers. The Argives believed that Hera recovered her virginity every year by bathing in a certain spring (Paus. viii. 22, 2), a belief which probably reflects the custom of ceremonial purification after marriage (see Frazer, *Adonis*, p. 176). Although Hera was not the bestower of feminine charm to the same extent as Aphrodite, she was the patron of a contest for beauty in a Lesbian festival (*καλλιστεία*). It is this relation to women which gives some slight plausibility to her identification with the moon, which is constantly associated with them.

Among her particular worshippers, at Argos and Samos, Hera was much more than the queen of heaven and the marriage-goddess. As the patron of these cities (*πολιούχος*) she held a place corresponding to that of Athena in Athens. In Argos the agricul-

tural character of her ritual is well marked; the first oxen used in ploughing were dedicated to her as *Ζευξιδία* ("lady of the yoke"); and the sprouting ears of corn were called "the flowers of Hera." She was worshipped as the goddess of flowers (*ἄνθεα*); girls served in her temple under the name of "flower-bearers," and a flower festival (*Ἡροσανθία*, *Ἡροάνθεια*) was celebrated by Peloponnesian women in spring. These rites recall our May day observance and give colour to the earth-goddess theory. On the other hand, it must be remembered that the patron deity of a Greek state had very wide functions; and it is not surprising to find that Hera (whatever her origin may have been) assumed an agricultural character among her own people, whose occupations were largely agricultural. So, although the warlike character of Hera was not elsewhere prominent, she assumed a militant aspect in her two chief cities; a festival called the Shield was part of the Argive cult, and there was an armed procession in her honour at Samos. The city-goddess, whether Hera or Athena, must be chief alike in peace and war.

The cow was the animal especially sacred to Hera both in ritual and in mythology. The Homeric epithet *βοώπις* may have meant "cow-faced" to the earliest worshippers of Hera (see Io) though by Homer and the later Greeks it was understood as "large-eyed," like the cow. A car drawn by oxen seems to have been widely used in the processions of Hera, and the cow was her most frequent sacrifice. The cuckoo was also sacred to Hera, who, according to the Argive legend, was wooed by Zeus in the form of the bird. In later times the peacock, which was still unfamiliar to the Greeks in the 5th century, was her favourite, especially at Samos.

Cult-statues.—A log at Thespieae, a plank at Samos, a pillar at Argos served to represent the goddess. In the archaic period of sculpture the *ξάρον* or wooden statue of the Samian Hera by Smilis was famous. The most celebrated statue of Hera was the chryselephantine work of Polycleitus, made for the Heraion at Argos soon after 423 B.C. Polycleitus seems to have fixed the type of Hera as a youthful matron, but unfortunately the exact character of her head cannot be determined. A majestic and rather severe beauty marks the conception of Hera in later art, of which the Farnese bust at Naples and the Ludovisi Hera are the most conspicuous examples.

HERACLEIA (Gr. *Ἡράκλεια*) or, in the Latin form, **HERACLEA**, the name of a large number of ancient cities founded by the Greeks.

1. **HERACLEA**, an ancient city of Lucania, near the modern Policoro, 3 m. from the coast of the gulf of Tarentum, between the rivers Aciris (Agri) and Siris (Sinni) about 13 m. S.S.W. of Metapontum. It was a Greek colony founded by the Tarentines who had been defeated by the Thurians in 433 B.C. Here Pyrrhus, king of Epirus, defeated the consul Laevinus in 280 B.C., after he had crossed the river Siris. In 278 B.C., probably in order to detach it from Tarentum, the Romans made a special treaty with Heraclaea, on such favourable terms that in 89 B.C. the Roman citizenship given to the inhabitants by the Lex Plautia Papiria was only accepted after considerable hesitation. Having accepted Roman citizenship, it became a *municipium*; part of a copy on bronze of the Lex Iulia Municipalis of 46 B.C. found between Heraclaea and Metapontum, is of the highest importance for our knowledge of that law. It was still of importance under the empire; a branch road from Venusia joined the coast road here: but the site is now marked by a few heaps of ruins. Its mediaeval representative was Anglona, once a bishopric, but now itself a heap of ruins.

There was another Heraclaea to which Herodotus (v. 46) refers, near Mount Eryx, founded by Dorieus not long after 500 B.C. and soon destroyed by the Carthaginians and Egesteans.

2. **HERACLEA MINOA**, an ancient town on the south coast of Sicily, at the mouth of the river Halycus (modern *Platani*) some 20 m. W.N.W. of Girgenti. It was founded by Selinus and was

always a border town between Carthaginian and Greek territory. It was taken by the Lacedaemonian colonists under Euryleon shortly before 500 but must have fallen into Carthaginian hands before Acragas (406). They lost it temporarily to Agathocles and Pyrrhus, but used it as a base in the first Punic war.

3. **HERACLEA PONTICA** (mod. *Bender Ereğli*), an ancient city on the coast of Bithynia in Asia Minor, at the mouth of the Kilijsu. It was founded by a Megarian colony, which soon subjugated the native Mariandynians and extended its power over a considerable territory. The prosperity of the city was utterly destroyed in the Mithridatic war. It was the birthplace of Heracleides Ponticus. The modern town is best known for its lignite coal-mines, from which Constantinople receives a good part of its supply.

4. **HERACLEA SINTICA**, a town in Thracian Macedonia, to the south of the Strymon, the site of which was sought by Leake at the village of Zervokhori, and identified by the discovery of local coins, while other authorities place it further north, to the west of Demir Hissar.

5. **HERACLEA**, a town on the borders of Caria and Ionia, near the foot of Mount Latmus. A temple and a rock cut theatre were visible a century ago. In its neighbourhood was the burial cave of Endymion.

6. **HERACLEA-CYBISTRA** (mod. *Ereğli* in the vilayet of Konia), under the name Cybistra, had some importance in Hellenistic times owing to its position near the point where the road to the Cilician Gates enters the hills. It lay in the way of armies and was more than once sacked by the Arab invaders of Asia Minor (A.D. 805 and 832). It became Turkish (Seljuk) in the 11th century. Modern Ereğli had grown from a large village to a town since the railway reached it from Konia and Karaman in 1904; and it has now an hotel and good shops. Three hours' ride S. is the famous "Hittite" rock-relief of Ivriz, representing a king (probably of neighbouring Tyana) adoring a god (see *HITTITES*). This was the first "Hittite" monument discovered in modern times (early 18th century, by the Swede Otter, an emissary of Louis XIV.).

7. **HERACLEA LYNCESTIS** (mod. *Monastir*) was a town in Macedonia, on the Via Egnatia.

For Heraclaea Trachinia see *TRACHIS*, and for Heraclaea Perinthus see *PERINTHUS*.

HERACLEA was also the name of one of the Sporades, between Naxos and Ios, which is still called Raklia, and bears traces of a Greek township with temples to Tyche and Zeus Lophites.

HERACLEIDES PONTICUS, Greek philosopher, born at Heraclaea in Pontus, flourished in the 4th century B.C. He was a pupil of Plato. According to Suidas, Plato, on his departure for Sicily, left his school in charge of Heracleides. Fantastic stories about him are told in Diogenes Laertius, v. c. 6. He is said to have written brilliant works on a wide range of subjects, ethical, grammatical, musical, rhetorical, historical, as well as geometrical and dialectical treatises. He is famous in the history of astronomy for having been the first to maintain that the apparent daily rotation of the heavens is accounted for, not by the motion of the stars round the earth, but by the rotation of the earth itself about its own axis; he also took a notable step towards the Copernican hypothesis by declaring that the planets Mercury and Venus revolve in circles round the sun as centre like satellites.

For details of his life and work see Otto Voss, *De Heraclidis Pontici vita et scriptis* (1896). (T. L. H.)

HERACLEON, a Gnostic who flourished c. A.D. 125, probably in the south of Italy. He appears to have regarded the divine nature as a vast abyss in whose *pleroma* were aeons of different orders,—emanations from the source of being. Midway between the supreme God and the material world was the Demiurgus, who created the latter, and under whose jurisdiction the animal soul of man proceeded after death, while his celestial soul returned to its origin. Origen, who treats Heracleon as a notable exegete, has preserved fragments of his commentary on the fourth gospel (brought together by Grabe in vol. ii. of his *Spicilegium*), while Clement of Alexandria quotes what appears to be a passage from a commentary on Luke. These writings are intensely mystical and allegorical.

HERACLEONAS, East Roman emperor (Feb.–Sept. 641), was the son of Heraclius (q.v.) and Martina. At the end of Heraclius' reign he obtained through his mother's influence the title of Augustus (638), and after his father's death was proclaimed joint emperor with his half-brother Constantine III. The premature death of Constantine, in May 641, left Heraclionas sole ruler. But a suspicion that he and Martina had murdered Constantine led soon after to a revolt, and to the mutilation and banishment of the supposed offenders. Nothing is known about Heraclionas after 641.

HERACLIDAE, the general name for the numerous descendants of Heracles (Hercules); the name is especially used in antiquity for Hyllus and his descendants, the leaders of the Dorian invasion of the Peloponnese. The Dorian invasion and the collapse of the Heroic civilization is represented in Greek tradition as the "return of the Heraclids," seeking their father's inheritance, primarily Argos, of which he had been defrauded by Eurystheus. The legend appears to have been reduced to order by Ephorus, and the date fixed at 1104 B.C. It is difficult to give a coherent account of the story owing to the variations in even the earliest tradition, and the intrusion into the story of a mass of quite worthless legend in later writings.

The two main traditions may be summarized thus—chiefly from Herodotus and Pindar. The first centres round Echemus, king of Arcadia, who defeated the Heraclidae at the Isthmus before the Trojan war. They covenanted to stay away for three generations. At the end of this period the three sons of Aristomachus returned to Peloponnesus, captured it and divided the territory, Temenus taking Argos, the sons of Aristodemus Sparta and Cresphontes Messene. The second, implicit in Herodotus' account of the coming of the Dorians, tells of the adoption by Aegimius, the Thesalian ancestor of the Dorians, of Hyllus as co-heir with his own sons (hence the Dorian tribes, Hylleis, Pamphyloi and Dymanes); and of the subsequent conquest of Peloponnesus by the three and their followers. It is difficult to reconcile these traditions, and, considered separately, each presents problems. It is probable that Messene was never Dorian until its conquest by Sparta.

There are further complications in addition to the confusion introduced by later writers; for instance, there is a Heraclid called Aletes (the Wanderer) who appears in Peloponnesus in one of the stories; he may have come from Rhodes. And Herodotus has a story of a Heraclid dynasty in Lydia, who ruled for the 505 years before the Mermnadae dynasty (685), the last being Candaules, who was killed by Gyges the founder of the Mermnad house.

See, for the historical bearing of these stories, art. **DORIANS**. The main ancient authorities in addition to Herodotus (*passim* and esp. i. 56; ix. 26) are Pindar, *Pyth.* ix., *Olymp.* vii. See also Müller's *Dorians*; and Busolt, *Griechische Gesch.*, i. 2, 7.

HERACLITUS (c. 540–475 B.C.), Greek philosopher, was born at Ephesus of distinguished parentage. Of his early life we know nothing except perhaps that he declined the nominal position of Basileus. (See **ARCHON**.) From his lonely life, from the extreme profundity of his philosophy and from his contempt for mankind he was called the "Dark Philosopher" in contrast to Democritus, the "Laughing Philosopher."

Heraclitus is in a sense the founder of metaphysics. Starting from the physical standpoint of the Ionian school, he accepted their idea of the unity of nature, but denied their theory of being. For him, all things are one, and this one is also the many, the "opposite tension" of the opposites constituting the unity of the one. Hot and cold good and evil, night and day, etc., are the same in the sense that they are inseparable halves of one and the same thing. This primary substance is fire. In nature the sole actuality is change. All things are becoming, but they appear to remain the same, for while fire (of which even the soul is made) is transformed into the other elements, these also are transformed into fire. This rhythm of events and order in change is the reason or *logos* of the universe. There is no evidence to show that Heraclitus believed in a general conflagration. Knowledge consists in comprehending the all-pervading harmony as embodied in the manifold of perception. Virtue consists in the subordination of the individual to the laws of this harmony as the universal rea-

son wherein alone true freedom is to be found. "The law of things is a law of Reason Universal; but most men live as though they had a wisdom of their own." Ethics here stands to sociology in a close relation.

Though much popular theology pervades his ethical teaching, he attacks the ceremonies of popular religion. After his death, the chief disciple of Heraclitus' teaching was Cratylus.

HERACLIUS (Ἡρακλείος) (c. 575–642), East Roman emperor, was born in Cappadocia. His father held high military command under the emperor Maurice, and as governor of Africa maintained his independence against the usurper Phocas (q.v.). When invited to head a rebellion against the latter, he sent his son with a fleet which reached Constantinople unopposed, and precipitated the dethronement of Phocas. Proclaimed emperor (610), Heraclius set himself to reorganize the utterly disordered administration. At first he found himself helpless before the Persian armies (see **PERSIA: Ancient History**; and **CHOSROËS II.**) of Chosroës II., which conquered Syria and Egypt and since 616 had encamped opposite Constantinople; in 618 he even proposed to abandon his capital and seek a refuge in Carthage, but at the entreaty of the patriarch he took courage. By securing a loan from the Church and suspending the corn-distribution at Constantinople, he raised sufficient funds for war, and after making a treaty with the Avars, who had nearly surprised the capital during an incursion in 619, he was at last able to take the field against Persia. During his first expedition (622) he failed to secure a footing in Armenia, whence he had hoped to take the Persians in flank, but by his unwearied energy he restored the discipline and efficiency of the army. In his second campaign (624–26) he penetrated into Armenia and Albania, and beat the enemy in the open field. After a short stay at Constantinople, which his son Constantine had successfully defended against renewed incursions by the Avars, Heraclius resumed his attacks upon the Persians (627). Though deserted by the Khazars, with whom he had made an alliance upon entering into Pontus, he gained a decisive advantage by a brilliant march across the Armenian highlands into the Tigris plain, and a hard-fought victory over Chosroës' general, Shahrbaraz, in which Heraclius distinguished himself by his personal bravery. A subsequent revolution at the Persian court led to the dethronement of Chosroës in favour of his son Kavadh II. (q.v.); the new king promptly made peace with the emperor, whose troops were already advancing upon the Persian capital Ctesiphon (628). Having secured his eastern frontier, Heraclius returned to Constantinople with the true cross, which in 629 he brought back in person to Jerusalem. On the northern frontier of the empire he kept the Avars in check by inducing the Serbs to migrate from the Carpathians to the Balkan lands so as to divert the attention of the Avars.

The triumphs which Heraclius had won did not bring him lasting popularity. In his civil administration he followed out his own ideas without deferring to the nobles or the Church, and the opposition which he encountered from these quarters went far to paralyse his attempts at reform. Worn out by continuous fighting and weakened by dropsy, Heraclius failed to show sufficient energy against the new peril that menaced his eastern provinces

towards the end of his reign. In 629 the Saracens made their first incursion into Syria (see CALIPHATE, section A, § 1); in 636 they won a notable victory on the Yermuk (Hieromax), and in the following years conquered all Syria, Palestine and Egypt. Heraclius made no attempt to retrieve the misfortunes of his generals, but evacuated his possessions in sullen despair. The remaining years of his life he devoted to theological speculation and ecclesiastical reforms. His religious enthusiasm led him to oppress his Jewish subjects; on the other hand he sought to reconcile the Christian sects, and to this effect propounded in his *Ecthesis* a conciliatory doctrine of monothelism. Heraclius died of dropsy in 642. He had been twice married; his second union, with his niece Martina, was frequently made a matter of reproach to him. In spite of his partial failures, Heraclius must be regarded as one of the greatest of Byzantine emperors, and his early campaigns were the means of saving the realm from almost certain destruction.

HERALD; for the mediaeval and modern functions of a herald, see HERALDRY.

Greek Heralds, So-called.—The word "herald" is commonly used to translate Gr. κήρυξ, which has various meanings. (1) In Homer, a κήρυξ is mostly a trusted attendant or retainer of a chieftain, one might almost say a gentleman of the bedchamber. We several times hear of them attending and waiting on their lords, performing confidential services for them, and so forth. But they also have official and public functions; they proclaim and execute the king's will—in which capacity it would seem that their persons are inviolable—and summon and keep order at the folk-moot. (2) These functions continue at later times, and we find heralds acting as inviolable messengers between states, even in time of war, proclaiming meetings of a senate, popular assembly, or court of law, reciting the formulae of prayer, etc., thereat, and summoning persons to attend. Hermes, himself the herald of the gods, is their patron and carries a herald's staff (*caduceus*, κηρύκειον; see HERMES). (3) Besides these paid functionaries of the State, there was a clan of *kerykes* at Eleusis, who had certain duties in connection with the mysteries. (4) The word, however, often means no more than a crier, whether at the Olympian or other games or simply at a sale or the like.

Latin "Heralds."—Setting aside the misuse of "herald" to translate *praeco* (crier, auctioneer), or *apparitor* (summoner, attendant on a magistrate), we may notice the real equivalent of the Greek κήρυξ in his capacity as an inviolable messenger, the *fetialis*. A college of *fetiales* existed from very early times; such an institution was by no means confined to Rome, and parallels to it are found among quite low savages, giving us the right to suppose that it had long been recognized in Italy before our earliest historical documents. At Rome, if a breach of international law by a neighbouring state was alleged, two *fetiales* at least were appointed, the *pater patratus*, who was the senior member of the deputation, and the *Verbenarius*, or carrier of the sacred herbs (*verbenae*, *sagmina*), which apparently represented the Roman territory. These went to the State in question and thrice solemnly demanded redress (*clarigeratio*); if this was not obtained within 30 days, they reported the matter at Rome; when war was voted they returned to the frontier, and flung a javelin, made of cornel-wood and having either an iron point or one end sharpened and hardened by fire (this clearly is the older form), into the hostile territory, calling on the gods to witness the justice of their cause. In later times, a plot of land in Rome, containing the famous *columna bellica* or pillar of war, was by a legal fiction made to represent hostile territory, and the javelin cast into it, thus avoiding the long journeys overseas to perform the ceremony. They also made treaties of peace, when the terms

had been agreed upon and ratified. For this purpose, the deputation carried flint knives, or a flint knife, which was the embodiment of Jupiter, and kept in one of his temples (*Iuppiter lapis*). They met the deputation of the other state; the terms of the treaty were read aloud; a pig was killed with the knife (hence the phrase *foedus ferire*, to smite a treaty-victim, for "to make a treaty," the Greeks said ὀρκία τάμνειν, to cut oath-victims, and had a very similar rite), and Jupiter was invoked to smite Rome in like manner, if Rome were the first wantonly to violate the treaty. The college of *fetiales*, though little is heard of it after 201 B.C., continued to exist throughout the empire.

HERALDRY. Although the word heraldry properly belongs to all the business of the herald (*q.v.*), it has long attached itself to that which in earlier times was known as armory, the science of armorial bearings.

History of Armorial Bearings.—In all ages and in all quarters of the world distinguishing symbols have been adopted by tribes or nations, by families or by chieftains. Greek and Roman poets describe the devices borne on the shields of heroes, and many such painted shields are pictured on antique vases. Rabbinical writers have supported the fancy that the standards of the tribes set up in their camps bore figures devised from the prophecy of Jacob, the ravening wolf for Benjamin, the lion's whelp for Judah and the ship of Zebulon. In the East we have such ancient symbols as the five-clawed dragon of the Chinese empire and the chrysanthemum of the emperor of Japan. In Japan, indeed, the systematized badges borne by the noble clans may be regarded as akin to the heraldry of the West, and the circle with the three asarum leaves of the Tokugawa shoguns has been made as familiar to us by Japanese lacquer and porcelain as the red pellets of the Medici by old Italian fabrics. Before the landing of the Spaniards in Mexico the Aztec chiefs carried shields and banners, some of whose devices showed after the fashion of a phonetic writing the names of their bearers; and the eagle on the new banner of Mexico may be traced to the eagle that was once carved over the palace of Montezuma. That mysterious business of totemism, which students of folk-lore have discovered among most primitive peoples, must be regarded as another of the forerunners of true heraldry, the totem of a tribe supplying a badge which was sometimes displayed on the body of the tribesman in paint, scars or tattooing. Totemism so far touches our heraldry that some would trace to its symbols the white horse of Westphalia, the bull's head of the Mecklenburgers and many other ancient armories.

When true heraldry begins in Western Europe nothing is more remarkable than the suddenness of its development, once the idea of hereditary armorial symbols was taken by the nobles and knights. Its earliest examples are probably still to be discovered by research, but certain notes may be made which narrow the dates between which we must seek its origin. The older writers on heraldry, lacking exact archaeology, were wont to carry back the beginnings to the dark ages, even if they lacked the assurance of those who distributed blazons among the angelic host before the Creation. Even in our own times old misconceptions give ground slowly. Georg Ruexner's *Thurnier Buch* of 1522 is still cited for its evidence of the tournament laws of Henry the Fowler, by which those who would contend in tournaments were forced to show four generations of arms-bearing ancestors. Yet modern criticism has shattered the elaborated fiction of Ruexner. In England many legends survive of arms borne by the Conqueror and his companions. But nothing is more certain than that neither armorial banners nor shields of arms were borne on either side at Hastings. The famous record of the Bayeux tapestry shows shields which in some cases suggest rudely devised armorial bearings, but in no case can a shield be identified as one which is recognized in the generations after the Conquest. So far is the idea of personal arms from the artist, that the same warrior, seen in

FIG. 1.—SHIELDS BEARING ARMS CHARACTERISTIC OF THE MIDDLE AGES

(1) Shield from seal of Robert de Pinkeny, an early example of parted arms. (2) Shield of Joan atte Pole, widow of Robt. Hemenhale, from her seal (1403), showing parted arms. (3) Shield of Beatrice Stafford from her seal (1404), showing her arms of Stafford between those of her husbands—Thomas, Lord Roos, and Sir Richard Burley. (4) Shield of John Talbot, first Earl of Shrewsbury (d. 1453), showing four coats quartered. (5) Shield of Richard Beauchamp, Earl of Warwick, from his garter stall-plate (after 1423). The arms are Beauchamp quartering Newburgh with a scocheon of Clare quartering Despenser. (6) Ralph de Monhermer (1301) showing shield of arms, helm with crest and mantle, horse-crest and armorial trappings. (7) Shield and crested helm with hat and mantle of Thomas Hengrave (1401). (8) Arms of William, Lord Hastings, from his seal (1477), showing shield, crowned and crested helm with mantle and supporters. (9) Badge of John of Wethamstede, abbot of St. Albans (d. 1465), from his tomb in the abbey church. (10) Rudder badge of Willoughby. (11) Badge of Daore of Gilsland and Daore of the North. (12) Ostrich feather badge of Beaufort, from a garter stall-plate of 1440. The silver feather has a quill of gobony silver and azure. (13 and 14) Mohun. (15) Montagu. (16) Dynham

different parts of the tapestry's history, has his shield with differing devices. A generation later, Anna Comnena, the daughter of the Byzantine emperor, describing the shields of the French knights who came to Constantinople, tells us that their polished faces were plain.

Of all men, kings and princes might be the first to be found bearing arms. Yet the first English sovereign who appears on his great seal with arms on his shield is Richard I. His seal of 1189 shows his shield charged with a lion ramping towards the sinister side. Since one half only is seen of the rounded face of the shield, English antiquaries have perhaps too hastily suggested that the whole bearing was two lions face to face. But the mounted figure of Philip of Alsace, count of Flanders, on his seal of 1164 bears a like shield charged with a like lion, and in this case another shield on the counterseal makes it clear that this is the single lion of Flanders. Therefore we may take it that, in 1189, King Richard bore arms of a lion rampant, while, nine years later, another seal shows him with a shield of the familiar bearings which have been borne as the arms of England by each one of his successors.

That seal of Philip of Alsace is the earliest known example of the arms of the great counts of Flanders. The ancient arms of the kings of France, the blue shield powdered with golden fleurs-de-lys, appear even later. Louis le Jeune, on the crowning of his son Philip Augustus, ordered that the young prince should be clad in a blue dalmatic and blue shoes, sewn with golden fleurs-

de-lys, a flower whose name, as "Fleur de Loys," played upon that of his own, and possibly upon his epithet name of Florus. A seal of the same king has the device of a single lily. But the first French royal seal with the shield of the lilies is that of Louis VIII. (1223-1226). The eagle of the emperors may well be as ancient a bearing as any in Europe, seeing that Charlemagne is said, as the successor of the Caesars, to have used the eagle as his badge. The emperor Henry III. (1039-1056) has the sceptre on his seal surmounted by an eagle; in the 12th century the eagle was embroidered upon the imperial gloves. At Mölsen in 1080 the emperor's banner is said by William of Tyre to have borne the eagle, and with the beginning of regular heraldry this imperial badge would soon be displayed on a shield. The double-headed eagle is not seen on an imperial seal until after 1414, when the bird becomes the recognized arms of the king of the Romans.

There are, however, earlier examples of shields of arms than any of these. A document of the first importance is the description by John of Marmoustier of the marriage of Geoffrey of Anjou with Maude the empress, daughter of Henry I., when the king is said to have hung round the neck of his son-in-law a shield with golden "lioncels." Afterwards the monk speaks of Geoffrey in fight, "pictos leones preferens in clypeo." Two notes may be added to this account. The first is that the enamelled plate now in the museum at Le Mans, which is said to have been placed over the tomb of Geoffrey after his death in 1151, shows him bearing a

long shield of azure with six golden lioncels, thus confirming the monk's story. The second is the well-known fact that Geoffrey's bastard grandson, William with the Long Sword, undoubtedly bore these same arms of the six lions of gold in a blue field, even as they are still to be seen upon his tomb at Salisbury. Some ten years before Richard I. seals with the three leopards, his brother John, count of Mortain, is found using a seal upon which he bears two leopards, arms which later tradition assigns to the ancient dukes of Normandy and to their descendants the kings of England before Henry II., who is said to have added the third leopard in right of his wife, a legend of no value. Mr. Round has pointed out that Gilbert of Clare, earl of Hertford, who died in 1152, bears on his seal to a document sealed after 1138 and not later than 1146, the three cheverons afterwards so well known in England as the bearings of his successors. An old drawing of the seal of his uncle Gilbert, earl of Pembroke (*Lansdowne MS.* 203), shows a cheveronny shield used between 1138 and 1148. At some date between 1144 and 1150, Waleran, count of Meulan, shows on his seal a pennon and saddle-cloth with a checkered pattern: the house of Warenne, sprung from his mother's son, bore shields checky of gold and azure. In the inventory of Norman seals made by M. Demay, there is among the archives of the Manche a grant by Eudes, seigneur du Pont, sealed with a seal and counterseal of arms, to which M. Demay gives a date as early as 1128; but this is an error; the date should be 1218. Another type of seal common in this 12th century shows the personal device which had not yet developed into an armorial charge. A good example is that of Enguerrand de Candavène, count of St. Pol, where, although the shield of the horseman is uncharged, sheaves of oats, playing on his name, are strewn at the foot of the seal. Five of these sheaves were the arms of Candavène when the house came to display arms. In the same fashion three different members of the family of Armenteres in England show one, two or three swords upon their seals, but there is no evidence of a coat of arms derived from these devices.

From the beginning of the 13th century arms upon shields increase in number. Soon the most of the great houses of the west display them with pride. Leaders in the field, whether of a royal army or of a dozen spears, saw the military advantage of a custom which made shield and banner things that might be recognized in the press. Although it is probable that armorial bearings have their first place upon the shield, the charges of the shield are found displayed on the knight's long surcoat, his "coat of arms," on his banner or pennon, on the trapper of his horse and even upon the peaks of his saddle. An attempt has been made to connect the rise of armory with the adoption of the barrel-shaped close helm; but even when wearing the earlier Norman helmet with its long nasal the knight's face was not to be recognized. The Conqueror, as we know, had to bare his head before he could persuade his men at Hastings that he still lived. Armory satisfied a need which had long been felt. When fully armed, one galloping knight was like another; but friend and foe soon learned that the gold and blue checkers meant that Warenne was in the field and that the gold and red vair was for Ferrers. Earl Simon at Evesham sent up his barber to a spying place and, as the barber named in turn the banners which had come up against him, he knew that his last fight was at hand. In spite of these things the growth of the custom of sealing deeds and charters had at least as much influence in the development of armory as any military need. By this way, women and clerks, citizens and men of peace, corporations and colleges, came to share with the fighting man in the use of armorial bearings. Arms in stone, wood and brass decorated the tombs of the dead and the houses of the living; they were broidered in bed-curtains, coverlets and copes, painted on the sails of ships and enamelled upon all manner of goldsmiths' and silversmiths' work. And, even by warriors, the full splendour of armory was at all times displayed more fully in the fantastic magnificence of the tournament than in the rougher business of war.

There can be little doubt that ancient armorial bearings were chosen at will by the man who bore them, many reasons guiding his choice. Crosses in plenty were taken. Old writers have asserted that these crosses commemorate the badge of the cru-

saders, yet the fact that the cross is the symbol of the faith was reason enough. No symbolism can be found in such charges as bends and fesses; they are on the shield because a broad band, aslant or athwart, is a charge easily recognized. Mediaeval wisdom gave every noble and magnanimous quality to the lion, and therefore this beast is chosen by hundreds of knights as their bearing. We have already seen how the arms of a Candavène play upon his name. In ancient shields almost all beasts and birds other than the lion and the eagle play upon the bearer's name. No object is so humble that it is unwelcome to the knight seeking a pun for his shield. Trivet has a three-legged trivet. The legends which assert that certain arms were "won in the Holy Land" or granted by ancient kings for heroic deeds in the field are for the most part worthless fancies.

Tenants or neighbours of the great feudal lords were wont to make their arms by differencing the lord's shield or by bringing some charge of it into their own bearings. Thus a group of Kentish shields borrow lions from that of Leyborne, which is azure with six lions of silver. Shirland of Minster bore the same arms differenced with an ermine quarter. Detling had the silver lions in a sable field. The Vipont ring or annelet is in several shields of Westmorland knights, and the cheverons of Clare, the cinquefoil badge of Beaumont and the sheaves of Chester can be traced in the coats of many of the followers of those houses. Sometimes the lord himself set forth such arms in a formal grant, as when the baron of Greystock grants to Adam of Blencowe a shield in which his own three chaplets are charges. The Whitgreave family of Staffordshire still show a shield granted to their ancestor in 1442 by the earl of Stafford, in which the Stafford red cheveron on a golden field is four times repeated.

Differences.—By the custom of the middle ages the "whole coat," which is the undifferenced arms, belonged to one man only and was inherited whole only by his heirs. Younger branches differenced in many ways, following no rule. In modern armory the label is reckoned a difference proper only to an eldest son. But in older times, although the label was very commonly used by the son and heir apparent, he often chose another distinction during his father's lifetime, while the label is sometimes found upon the shields of younger sons. Changing the colours or varying the number of charges, drawing a bend or baston over the shield or adding a border are common differences of cadet lines. Beauchamp, earl of Warwick, bore "Gules with a fesse and six crosslets gold." His cousins are seen changing the crosslets for martlets or for billets. Bastards difference their father's arms, as a rule, in no more striking manner than the legitimate cadets. Towards the end of the 14th century we have the beginning of the custom whereby certain bastards of princely houses differenced the paternal arms by charging them upon a bend, a fesse or a chief, a cheveron or a quarter. Before his legitimation the eldest son of John of Gaunt by Katharine Swinford is said to have borne a shield party silver and azure with the arms of Lancaster on a bend. After his legitimation in 1397 he changed his bearings to the royal arms of France and England within a border gobony of silver and azure. Warren of Poynton, descended from the last earl Warenne and his concubine, Maude of Neirford, bore the checkered shield of Warenne with a quarter charged with the ermine lion of Neirford. By the end of the middle ages the baston under continental influence tended to become a bastard's difference in England and the jingle of the two words may have helped to support the custom. About the same time the border gobony began to acquire a like character. The "bar sinister" of the novelists is probably the baston sinister, with the ends coupé, which has since the time of Charles II. been familiar on the arms of certain descendants of the royal house. But it has rarely been seen in England over other shields; and, although the border gobony surrounds the arms granted to a peer of Victorian creation, the modern heralds have fallen into the habit of assigning, in nineteen cases out of twenty, a wavy border as the standard difference for illegitimacy.

Although no general register of arms was maintained it is remarkable that there was little conflict between persons who had chanced to assume the same arms. The famous suit in which Scrope, Grosvenor and Carminow all claimed the blue shield with

the golden bend is well known, and there are a few cases in the 14th century of like disputes which were never carried to the courts. But the men of the middle ages would seem to have had marvellous memories for blazonry; and we know that rolls of arms for reference, some of them the records of tournaments, existed in great numbers. A few examples of these remain to us, with painted shields or descriptions in French blazon, some of them containing many hundreds of names and arms.

To women were assigned, as a rule, the undifferenced arms of their fathers. In the early days of armory married women—well-born spinsters of full age were all but unknown outside the walls of religious houses—have seals on which appear the shield of the husband or the father or both shields side by side. But we have some instances of the shield in which two coats of arms are parted or, to use the modern phrase, "impaled." Early in the reign of King John, Robert de Pinkeny seals with a parted shield. On the right or dexter side—the right hand of a shield is at the right hand of the person covered by it—are two fusils of an indented fesse: on the left or sinister side are three waves. The arms of Pinkeny being an indented fesse, we may see in this shield the parted arms of husband and wife—the latter being probably a Basset. In many of the earliest examples, as in this, the dexter half of the husband's shield was united with the sinister half of that of the wife, both coats being, as modern antiquaries have it, dimidiated. This "dimidiation," however, had its inconvenience. With some coats it was impossible. If the wife bore arms with a quarter for the only charge, her half of the shield would be blank. Therefore the practice was early abandoned by the majority of bearers of parted shields although there is a survival of it in the

fact that borders and tressures continue to be "dimidiated" in order that the charges within them shall not be cramped. Parted shields came into common use from the reign of Edward II., and the rule is established that the husband's arms should take the dexter side. There are, however, several instances of the contrary practice. On the seal (1310) of Maude, wife of John Boutetort of Halstead, the engrailed saltire of the Boutetorts takes the sinister place. A twice-married woman would sometimes show a shield charged with her paternal arms between those of both of her husbands, as did Beatrice Stafford in 1404, while in 1412 Elizabeth, Lady of Clinton, seals with a shield pale with five coats—her arms of la Plaunche between those of four husbands. In most cases the parted shield is found on the wife's seal alone. Even in our own time it is recognized that the wife's arms should not appear upon the husband's official seal, upon his banner or surcoat or upon his shield when it is surrounded by the collar of an order. Parted arms, it may be noted, do not always represent a husband and wife. Richard II. parted with his quartered arms of France and England those ascribed to Edward the Confessor, and parting is often used on the continent where quartering would serve in England. In 1497 the seal of Giles Daubeney and Reynold Bray, fellow justices in eyre, shows their arms parted in one shield. English bishops, by a custom begun late in the 14th century, part the see's arms with their own. By modern English custom a husband and wife, where the wife is not an heir, use the parted coat on a shield, a widow bearing the same upon the lozenge on which, when a spinster, she displayed her father's coat alone. When the wife is an heir, her arms are now borne in a little scoccheon above those of her husband. If the husband's arms be in

an unquartered shield the central charge is often hidden away by this *scocheon*.

The practice of marshalling arms by quartering spread in England by reason of the example given by Eleanor, wife of Edward I., who displayed the castle of Castile quartered with the lion of Leon. Isabel of France, wife of Edward II., seals with a shield in whose four quarters are the arms of England, France, Navarre and Champagne. Early in the 14th century Simon de Montagu, an ancestor of the earls of Salisbury, quartered with his own arms a coat of azure with a golden griffon. In 1340 we have Laurence Hastings, earl of Pembroke, quartering with the Hastings arms the arms of Valence, as heir of his great-uncle Aymery, earl of Pembroke. In the preceding year the king had already asserted his claim to another kingdom by quartering France with England, and, after this, quartered shields became common in the great houses whose sons were carefully matched with heirs female. When the wife was an heir the husband would quarter her arms with his own, displaying, as a rule, the more important coat in the first quarter. Marshalling becomes more elaborate with shields showing both quarterings and partings, as in the seal (1368) of Sibil Arundel, where Arundel (Fitzalan) is quartered with Warenne and parted with the arms of Montagu. In all, save one, of these examples the quartering is in its simplest form, with one coat repeated in the first and fourth quarters of the shield and another in the second and third. But to a charter of 1434 Sir Henry Bromflete sets a seal upon which Bromflete quarters Vesci in the second quarter, Aton in the third and St. John in the fourth, after the fashion of the much earlier seal of Edward II.'s queen. Another development is that of what armorists style the "grand quarter," a quarter which is itself quartered, as in the shield of Reynold Grey of Ruthyn, which bears Grey in the first and fourth quarters and Hastings quartered with Valence in the third and fourth. Humphrey Bourchier, Lord Cromwell, in 1469, bears one grand quarter quartered with another, the first having Bourchier and Lovaine, the second Tattershall and Cromwell.

The last detail to be noted in mediaeval marshalling is the introduction into the shield of another surmounting shield called by old armorists the "innerscocheon" and by modern blazoners the "inescutcheon." John the Fearless, count of Flanders, marshalled his arms in 1409 as a quartered shield of the new and old coats of Burgundy. Above these coats a little *scocheon*, borne over the crossing of the quartering lines, had the black lion of Flanders, the arms of his mother. Richard Beauchamp, the adventurous earl of Warwick, who had seen most European courts during his wanderings, may have had this shield in mind when, over his arms of Beauchamp quartering Newburgh, he set a *scocheon* of Clare quartering Despenser, the arms of his wife Isabel Despenser, co-heir of the earls of Gloucester. The seal of his son-in-law, the King-Maker, shows four quarters—Beauchamp quartering Clare, Montagu quartering Monthermer, Nevill alone, and Newburgh quartering Despenser. An interesting use of the *scocheon en surtout* is that made by Richard Wydville, Lord Rivers, whose garter stall-plate has a grand quarter of Wydville and Prouz, quartering Beauchamp of Hache, the whole surmounted by a *scocheon* with the arms of Rieviers or Rivers, the house from which he took the title of his barony. On the continent the common use of the *scocheon* is to bear the paternal arms of a sovereign or noble, surmounting the quarterings of his kingdoms, principalities, fiefs or seigniories. The prince of Wales bore the arms of Saxony above those of the United Kingdom differenced with his silver label. Marshalling takes its most elaborate form, the most removed from the graceful simplicity of the middle ages, in such shields as the "Great Arms" of the Austrian empire, wherein are nine grand quarters each marshalling in various fashions from three to eleven coats, six of the grand-quarters bearing *scocheons en surtout*, each *scocheon* ensigned with a different crown.

Crests.—The most important accessory of the arms is the crested helm. Like the arms it has its pre-heraldic history in the crests of the Greek helmets, the wings, the wild boar's and bull's heads of Viking headpieces. A little roundel of the arms of a Japanese house was often borne as a crest in the Japanese helmet, stepped in a socket above the middle of the brim. The 12th-

century seal of Philip of Alsace, count of Flanders, shows a demi-lion painted or beaten on the side of the upper part of his helm, and upon his seal of 1198 King Richard Coeur de Lion's barrel-helm has a leopard upon the semicircular comb-ridge, the edge of which is set off with feathers arranged as two wings. Crests, however, came slowly into use in England, although before 1250 Roger de Quincy, earl of Winchester, is seen on his seal with a wyver upon his helm. Of the long roll of earls and barons sealing the famous letter to the pope in 1301 only five show true crests on their seals. Two of them are the earl of Lancaster and his brother, each with a wyver crest like that of Quincy. One, and the most remarkable, is John St. John of Halmaker, whose crest is a leopard standing between two upright palm branches. Ralph de Monhermer has an eagle crest, while Walter de Moncy's helm is surmounted by a fox-like beast. In three of these instances the crest is borne, as was often the case, by the horse as well as the rider. Others of these seals to the barons' letter have the fan-shaped crest without any decoration upon it. But as the furniture of tournaments grew more magnificent the crest gave a new field for display, and many strange shapes appear in painted and gilded wood, metal, leather or parchment above the helms of the jousts. The Berkeleys, great patrons of abbeys, bore a mitre as their crest painted with their arms, like crests being sometimes seen on the continent where the wearer was *advocatus* of a bishopric or abbey. The whole or half figures or the heads and necks of beasts and birds were employed by other families. Saracens' heads topped many helms, that of the great Chandos among them. Astley bore for his crest a silver harpy standing in marsh-sedge, a golden chain fastened to a crown about her neck. Dymoke played pleasantly on his name with a long-eared moke's scalp. Stanley took the eagle's nest in which the eagle is lighting down with a swaddled babe in his claws. Many early helms, as that of Sir John Loterel, painted in the Loterel psalter, repeat the arms on the sides of a fan-crest. Howard bore for a crest his arms painted on a pair of wings, while simple "bushes" of feathers are seen in great plenty. The crest of a cadet is often differenced like the arms, and thus a wyver or a leopard will have a label about its neck. The Montagu griffon on the helm of John, marquess of Montagu, holds in its beak the gimel ring with which he differenced his father's shield. His brother, the King-Maker, following a custom commoner abroad than at home, shows two crested helms on his seal, one for Montagu and one for Beauchamp—none for his father's house of Nevill. It is often stated that a man, unless by some special grace or allowance, can have but one crest. This, however, is contrary to the spirit of mediaeval armory in which a man, inheriting the coat of arms of another house than his own, took with it all its belongings, crest, badge and the like. The heraldry books, with more reason, deny crests to women and to the clergy, but examples are not wanting of mediaeval seals in which even this rule is broken. It is perhaps unfair to cite the case of the bishops of Durham who ride in full harness on their palatinate seals; but Henry Despenser, bishop of Norwich, has a helm on which the winged griffon's head of his house springs from a mitre, while Alexander Nevill, archbishop of York, seals with shield, supporters and crowned and crested helm like those of any lay magnate. A seal cut for the wife of Thomas Chetwode, a Cheshire squire, has a shield of her husband's arms parted with her own and surmounted by a crowned helm with the crest of a demi-lion; and this is not the only example of such bearings by a woman.

Before passing from the crest let us note that in England the juncture of crest and helm was commonly covered, especially after the beginning of the 15th century, by a torse or "wreath" of silk, twisted with one, two or three colours. Coronets or crowns and "hats of estate" often take the place of the wreath as a base for the crest, and there are other curious variants. With the wreath may be considered the mantle, a hanging cloth which, in its earliest form, is seen as two strips of silk or sendal attached to the top of the helm below the crest and streaming like pennants as the rider bent his head and charged. Such strips are often displayed from the conical top of an uncrested helm, and some ancient examples have the air of the two ends of a stole or of

the *infulae* of a bishop's mitre. The general opinion of antiquaries has been that the mantle originated among the crusaders as a protection for the steel helm from the rays of an Eastern sun; but the fact that mantles take in England their fuller form after our crusading days were over seems against this theory. When the fashion for slittering the edges of clothing came in, the edges of the mantle were slittered like the edge of the sleeve or skirt, and, flourished out on either side of the helm, it became the delight of the painter of armories and the seal engraver. Modern heraldry in England paints the mantle with the principal colour of the shield, lining it with the principal metal; this in cases where no old grant of arms is cited as evidence of another usage. The mantles of the king and of the prince of Wales are, however, of gold lined with ermine and those of other members of the royal house of gold lined with silver. In ancient examples there is great variety and freedom. Where the crest is the head of a griffon or bird the feathering of the neck will be carried on to cover the mantle. Other mantles will be powdered with badges or with charges from the shield, others checkered, barred or paled. More than thirty of the mantles enamelled on the stall-plates of the mediaeval Garter-knights are of red with an ermine lining, tinctures which in most cases have no reference to the shields below them.

Supporters.—Shields of arms, especially upon seals, are sometimes figured as hung round the necks of eagles, lions, swans and griffons, as strapped between the horns of a hart or to the boughs of a tree. Badges may fill in the blank spaces at the sides between the shield and the inscription on the rim, but in the later 13th and early 14th centuries the commonest objects so serving are sprigs
